SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 30, 1892.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOLUME X. (NEW SERIES.)

FROM JULY 1, 1892, TO DECEMBER 30, 1892.

LONDON:
Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1892

INDEX TO VOL. X. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

THE

ELECTRICAL ENGINEER.

No. 1, Vol. X. LONDON, JULY 1, 1892. PRICE 3D.

NOTES.

Manchester Town Hall.—Tenders for wiring this building must be sent in by July 5th to the Gas Committee, Manchester.

Antwerp.—An electric railway between Antwerp and Brussels, to do the journey in 25 minutes each way, is proposed to be carried out shortly.

Titles.—A good title for a play depending upon a message by telephone would be "Are you there?" It would be equally good as a general motto for the "National," especially the "query."

Carshalton.—Tenders are asked for the lighting of Carshalton with gas, oil, or other illuminant, at per lamp, exclusive of the cost of columns and lanterns, for 12 months from end of July. Tenders to Mr. J. W. Manley, clerk, by July 6.

Electric Traction in Belgium.—An electric overhead conductor railway is thought of from Place Rouppe to La Petite Espinette. The Thomson-Houston system have the matter in hand. The present traction is by steam engines.

Varley Testimonial.—The meeting called for to-day (Friday), at 4 p.m., with reference to the proposed Varley testimonial, will be held in No. 4 room, Westminster Palace Hotel, instead of at the offices of the Institution of Electrical Engineers.

Electric Cranes.—Besides the contract for two electrical cranes for the Southampton Harbour Board, Messrs. J. G. Statter and Co. have recently secured the order for three 23-unit dynamos at Lord Rothschild's installation at Tring Park.

Alternate-Current Dynamos.—Messrs. Mather and Platt have sent us their catalogue of alternate-current dynamos, showing machines both with direct-driven exciter and separately excited. They are for 1,000 to 2,000 volts, and from 16 up to 200 amperes.

Guildhall.—At the meeting of the Commissioners of Sewers on Tuesday, on the motion of Mr. Graham King, seconded by Mr. Williamson, it was referred to the engineer to submit to the Court the cost of lighting the Court-room and offices by means of electricity.

Spanish Telegraphs.—The Direct Spanish Telegraph Company, Limited, state that the Spanish inland telegraphic system, which has been stopped since the 20th ult., is now working, and they have direct communication with Madrid and all parts of Spain by their Bilbao cable.

Hove.—Referring to the inactivity of the special committee appointed to consider the subject of electric lighting at Hove, a member of the Council (Mr. Usher Robins) suggested at a meeting last week that the committee shall be renamed the "Electric Darkness Committee."

Lithanode Cells.—A considerable number of road-cars have now been fitted with lithanode battery lamps. A type of solid accumulator which we described some months ago is being developed, and is likely, we think, to render considerable service in accumulator traction.

Southampton.—A letter was read at the Southampton Town Council meeting last week from Mr. J. T. Hamilton, secretary of the Southampton Electric Light and Power Company, offering to supply electric power for lighting the municipal offices and other public buildings. This was referred to the Estates Committee.

Central Electric Railway.—Lord Morley's Committee of the House of Lords last Friday passed the Bill promoted by the Central London Railway Company empowering them to extend their authorised system from the Mansion House to Liverpool-street Station. This Bill has now been sanctioned by both Houses.

Conversazione.—The *conversazione* of the Institution, it will be remembered, takes place to-night (Friday), and a large meeting may be expected. In view of the limited amount of cloak-room at the Royal Institute of Painters in Water Colours, it would be desirable if visitors were to use soft hats or opera hats on the occasion.

Huddersfield.—The Local Government Board have sanctioned the borrowing of £12,000 for buildings in connection with electric lighting, and £38,000 for general purposes in connection with electric lighting, the former to be repaid in 30 years, the latter in 15 years. It has been decided to insure the tramway boilers.

Guildford.—At last meeting of the Guildford Town Council, the town clerk stated that he had received a letter from Mr. J. N. Shoolbred, enclosing his report on the electric lighting of the town. It was agreed to read the report in committee at the conclusion of the general business, and then to refer it to the Electric Light Committee.

The Election.—The Postmaster-General has issued notices warning telegraph operators not to approach candidates with references to their grievances, and forbidding meetings held without notice to the department, or without official reporter. The telegraphists greatly object to this action as curtailing their privileges as holders of the franchise.

Paignton.—Two tenders were received at the last meeting of the Paignton Local Board for keeping the electric bells connecting the police station with the fire stations in order for 12 months. Mr. John Toby tendered for £12. 12s., with certain prices for new materials; Messrs. McCormack tendered for £14. The matter was referred to the same committee as dealt with the fire brigade question, being found somewhat complicated.

Electioneering Lamps.—Colonel Wyndham Murray has been furnished with a portable electric handlamp for carriage use or for lecture purposes, made by the Lithanode Company. The lamp, which is handsomely mounted, is provided with two socket contacts, so that the light is given either generally or cast downwards with the glare guarded

from the speaker's eyes. It is very useful form of electric handlamp.

Midget Arc Lamps.—We have recently carried out some tests with the well-named "Midget" arc lamp. It takes five to six amperes at 40 to 45 volts, giving about 200 c.p., and for interior work is an admirable arc lamp. It burns noiselessly and steadily, and the small opal globe with which it is provided allows it to give a very soft and pleasant, though brilliant, light.

Electric Pumping Plant. — Messrs. Ernest Scott and Mountain have just completed a large electric pumping plant to the order of Messrs. G. B. and T. E. Forster for North Seaton Colliery. These pumps are claimed to be the largest electric pumps that have up to the present been made. We hope to be able to give full details when the installation is at work at the colliery.

Bournemouth.—Notice was received by the Bournemouth Town Council at their last meeting from the Bournemouth and District Electric Supply Company of their intention to lay underground mains along several principal roads, and it was resolved that consent be given subject to the company depositing plans drawn to a proper scale, and subject to the approval of the surveyor.

Electric Sailing Gig.—H. Smith, Esq., of Stile Hall, Chiswick, has had an electric sailing gig constructed for use on the Norfolk Broads. The boat is built of teak, and runs at 6½ miles an hour, being fitted with electric motor driven by E.P.S. cells placed below the water-line. The boat can be rowed, sailed, or electrically propelled at pleasure, accommodating six persons comfortably.

Alternators in Parallel.—With reference to our note on parallel running of alternators, we are informed that at the Bournemouth central station the Mordey alternators have been run in parallel as required for nearly three years—it is, indeed, the only possible way for them to run, as there is only one main into the town. The machines are two of 37 units and three of 75 units, driven by Brush engines.

Fuse Wires.—Mr. Chas. Wirt, who has devised some good forms of fuses, says the two following rules, the result of much practical experience, if adopted, would save much hesitation and confusion: (1) The length of any fuse should be not less than 20 times its diameter; (2) the length of any fuse should be not less than 1in. for every 100 volts on the circuit in which it is used. The lengths apply to the fuse wire proper, exclusive of terminals.

Personal.—Prof. Francis B. Crocker, president of the New York Electrical Society, is now on a visit to England. Prof. Crocker holds the chair of electrical engineering at Columbia College. He is one of the joint inventors of the Crocker-Wheeler motor, which has met with the greatest success of any small motor, over 100,000 having been put in use in America. Prof. Crocker is a young man, and a prominent official in many electrical organisations in the States.

Electric Cart.—The Ward Electrical Car Company have a brand-new electric cart constructed which will be sent out for use on the streets shortly. The cart, being electric and very much of a novelty, will be used for advertising purposes—and, if we are not misinformed, by a certain establishment whose electricity is mostly flannel. Such are the virtues of anything electric. The Ward Company, by the way, have just taken new premises at 75, Victoria-street, and the electric omnibuses are promised as still coming shortly.

Ferranti Meters.—The demand for small electric meters is now rapidly increasing, and orders received for r meters show a considerable proportion of five-ampere instruments, a size Messrs. Ferranti have recently commenced to make. This demand for small sizes seems to indicate that the number of small consumers is on the increase—a gratifying sign which supply companies will be glad enough to note, and will soon feel in their load diagrams. In this kind of business as well as with the baker, "It's the penny loaf that pays."

Manchester Art Gallery. — The Manchester Art Gallery Committee invite suggestions and tenders from electrical engineers as to the best method of illuminating the entrance hall at the Art Gallery, Moseley-street; also for the lighting of the two new galleries with incandescent lamps similar to the system now in use at the present galleries. The various lights in entrance hall and two new galleries to be supplied from the present dynamos. Further particulars will be supplied by the city surveyor, Town Hall, Manchester. Tenders to be delivered at above office by July 7.

Board of Trade Unit.—The statement having been copied all over the world that the British Board of Trade had determined to call their unit of electrical power *(1,000* watts for one hour) the "kelvin," it is evidently necessary again to call attention to the fact that this proposed name has been abandoned by personal request of Lord Kelvin. The choice still seems to lie between the words "Board of Trade unit," the simple "supply unit"—suggested by Lord Kelvin as an alternative—and the more scientific "kilowatt-hour." The latter is certainly to be preferred for technical use.

Struck by Lightning.—M. Boens gives an account in the Belgian medical *Bulletin* of two young women who were struck by lightning on July 27, 1891, at Nalinnes, Namur, during a violent storm. They were taken to the village doctor, who treated them continuously for two hours, when signs of returning life were seen, and at three o'clock next morning consciousness of both returned, one being soon well, but the other being left with a profound sciatica. Her tongue was also paralysed for two months, but both eventually recovered. The moral which M. Boens justly emphasises is that efforts to revive those struck by lightning should not too soon be given up, as continuous attempts to restore respiration during several hours may result in restitution of life.

Telephone v. Telegraph.—No wonder the Government Post Office is getting fearful that the spread of telephony may interfere with its telegraph business. No wonder they have decided to take the matter into their hands—the question was certainly getting serious. Major Flood Page, at the deputation to the Board of Trade, said that the telephone companies in Great Britain had distributed last year 160 million messages, against a total of 66 millions by the Post Office. We see that a journalist, M. Jean Martin, of the College of Preceptors, advertises he will telephone in French a message of about 400 words for a guinea, the charge for which under old conditions by telegraph would have been 66s., and he evidently makes a good profit for the French and shorthand part of it. The "telepham" will cut out the "telegram."

Wales.—An installation of electric light has been introduced at The Quinta, a well-known establishment at Weston Rhyn, North Wales. The engine and dynamo are laid in the engine-shed near the offices, the building having been rearranged for the purpose. The installation has been carried out by Messrs. B. Verity and Sons, London, the dynamo being of the Elwell-Parker type, driven by a Marshall 8-h.p. vertical engine, with boiler, the whole being laid on thick beds of concrete. Cables are laid to supply light in the house, conservatory, the offices, and the stables. The number of lamps fixed is 134, eight and

16 c.p. The installation includes a storage battery of 53 cells. The agent, Mr. W. E. Frith, superintended the work. The installation is the first in this neighbourhood on so large a scale, and there is no doubt that others in the neighbourhood will follow the example.

Bradford Tramways.—Our readers will be glad to hear that the experiments undertaken by Messrs. Easton and Anderson, in conjunction with Mr. M. Holroyd Smith, on behalf of the Bradford Corporation, to demonstrate the efficiency of electric energy in propelling tramcars up steep hills, have been brought to a successful conclusion, and arrangements are now being made for the construction and equipment of two miles of line where the average rise in the total length is 1 in 24, the road in many places being as steep as 1 in 13·3. The Corporation has consented to allow the temporary overhead conductors used for the demonstration to remain in position for another fortnight, in order that gentlemen from other towns interested in tramways may witness the running of the car. Anyone desiring personally to inspect the tramcar and its working can obtain the necessary permission on application to the London office of Messrs. Easton and Anderson, Limited, 3, Whitehall place.

Lemberg Exhibition.—An international exhibition of building materials will be opened at Lemberg, under the auspices of His Excellency the Governor of Galicia, on the 30th August and closed on the 20th September, 1892. It will comprise all the materials falling within the province of the architectural line, as stone, bricks, marble, cement, lime, timber and iron, locksmith's work, forged goods, metals employed in architecture, roofs, carpenter's work, glass, asphalte, waterproofs, paints, lacquers, varnish, paper hangings, tapestry, water supplies, pumping apparatus, bathing contrivances, ventilators, lighting materials, sewers, lifts, arrangements for the extinguishing of fire, house telegraphs, telephones, special arrangements chiefly of a hygienic nature. The executive committee meets at Lemberg. A special jury will allot medals to the exhibitors, which will be put to the disposal of the committee by the Austro-Hungarian Government. Foreign parties interested in this exhibition and requiring information are requested to apply without delay to Mr. Arthur Gobeit, at Prague, Karolinenthal, the delegate appointed for abroad, who is also ready upon request to charge himself with the representation of the foreign exhibitors for the term of the exhibition.

Telegraphs Bill.—In the House of Lords on Thursday, the 23rd ult., the House went into committee on the Telegraphs Bill. An amendment by Viscount Midleton was rejected. Lord Balfour of Burleigh moved an amendment on Clause 6 preserving the jurisdiction of the Commissioners of Sewers in the City of London, and obviating the possibility of there being any difference between the local authority exercising the powers under the Bill and the local authority whose consent was necessary under the Electric Lighting Act, 1882. The amendment was agreed to, and the Bill passed through committee without further amendment. In the House of Commons, on Monday, on the order for the consideration of the Lords amendment to this Bill, Sir J. Lubbock said that this Bill had been very rapidly passed through its stages in that House. It in some respects affected the powers of the London County Council, which, however, had had no opportunity of considering it. The vice-chairman of the Council, on behalf, as he understood, of the Parliamentary Committee, objected to the measure. At the same time, he did not feel justified in endeavouring to throw out the Bill, but he hoped that in future measures affecting London a longer time would be allowed for consideration. Mr. Pickersgill objected, but on division the Lords' amendments were agreed to.

Electric Tricycles.—The desires of those cyclists of the *dolce far niente* type, who wish electricity to do for them what other and more vigorous (if more heated) devotees do with their legs, must have received a rude shock last week in the disappearance from the scene of the Vaughan-Sherrin battery and motor. Described by nearly every paper in London, and favourably reported on by no less an authority than Prof. S. P. Thompson, this iron-manganese battery and special motor yet does not seem to have sufficient solid qualities of efficiency and economy behind it to make it go—or rather to make the tricycle go—for the battery syndicate itself is gone—voluntarily wound up by the shareholders. Alas for our hopes—and we were promised a trip up the river in a primary battery launch driven on this plan! The cyclists must evidently wait: and when electricity is applied to this wonderful modern machine—the cycle—it should be rather in a kind of Ward Leonard arrangement, by which the cyclists should work calmly always at the same speed, and the torque and speed of machine should vary at the motor. This, and not the actual carrying of a battery to do all the work, might be working in the direction of greatest usefulness.

Society of Arts.—One of the scientifically social events of the year is always the *conversazione* of the Society of Arts, when professors, celebrities, and their wives and relations meet in almost ideal surroundings to exchange compliments, listen to the music, and inspect the treasures of art and science at the national museum of Great Britain. Wednesday's function was no exception to the universally successful gatherings of the society, and for hours distinguished throngs were received by Sir Philip Cunliffe Owen (in the absence of Sir Richard Webster), wandered round the galleries, listened to the Royal Engineers' band, the exquisite singing and playing of the Meistersingers, or promenaded on the grass in the quadrangle to the accompaniment of music by the Scots' Guards, electric light, and brilliant costumes. Amongst electrical celebrities present were Prof. S. P. Thompson, Prof. Perry, Mr. J. W. Swan, Mr. Garcke, Mr. Ferranti, Mr. Kapp, Mr. Webb, and a large number of others, bearers of well-known names. There were also present Lord Stanley, Sir H. Doulton, Prof. Dewey, and the members of the council. The whole of the courts and corridors of the ground floors were open, together with the galleries containing the Raphael cartoons, the Sheepshanks collection, the William Smith collection of water-colour drawings, the Dyce and Forster pictures, and the Chantrey Bequest, all brilliantly illuminated by the electric light, making a reception scene that is not easily forgotten.

Glover's Cables.—Messrs. Walter T. Glover and Co., the well known cable manufacturers of Salford, certainly are determined to advance with the times. We see it in every sign. No sooner do we hear of a patent steel flexible piping, than the firm use it for covering cables; no sooner do we require anti-induction wires than they bring them out—flexibles, concentrics, high insulation, waterproof insulation, cables for central stations, houses, ships, and mines—all are brought forward with just that amount of detail that installing engineers should be able to find exactly what they require. And now they have brought out their catalogue on a new plan, so that requirements shall be still easier to find. We much admire the ingenious way in which details and particulars of all kinds are given in such convenient compass—and the book is made up to be a really handsome work instead of a mere dry catalogue. There is a finger-index cut into the leaves to turn up any detail you want at

once, and, above all, the reference numbers are now all arranged on a capital plan, to such a manner that they really describe what they stand for. For instance, you want a $^{19}/_{21}$ vulcanised rubber cable for 2,000 volts, 750 to 100 megohms per mile. You find this in class 66, and you wire for a mile of "No. 192166"—nothing could be simpler. A number of new and useful tables are added, making it quite a useful work of reference. We advise every electrical engineer to procure a copy of Glover's catalogue.

Electric Cranes.—The Works Committee of the Southampton Town Council reported in regard to tenders on amended designs for electric cranes that they had received the following tenders for the supply of two electric cranes:

	Two cranes.	Accessories, mains, etc.	Total.
Keys' Electric Company...	£2,700	... £1,175	... £3,875
Crompton and Co.	3,209	... 234	... 3,443
Statter and Co.	2,150	... 237	... 2,387

Messrs. Statter and Co.'s tender was recommended for acceptance. The surveyor, Mr. J. G. Poole, reported that the estimated cost of strengthening the quay to take the proposed gantrys and cranes was £665. Councillor Bone moved the adoption of the report, and said that the result of the visit of the deputation to Hamburg showed that the Hamburg electric cranes were much superior to those they proposed to have on the pier. Messrs. Statter's was the lowest tender, as on a former occasion. The cranes were to be made by an English firm. The Corporation would have to spend £600 in strengthening the quay. The junior bailiff, as one of the deputation which went to Hamburg, seconded, and said that it was a happy consummation of what they had in hand since November, 1889. He believed that they had taken a step in the right direction, and when they had the cranes in six months' time the Harbour Board would be the first persons in the kingdom to use electric cranes on their premises. Now that the railway company had possession of the docks, he hoped that they too would see that it would be policy on their part to follow on the same lines. The report was unanimously adopted.

Ship Struck by Lightning.—The following detailed account of the effect of lightning on a ship's compass recently is extremely interesting, and is probably almost unique: "Captain Woodcock is master of the 'Capella,' a steel steamer of 2,036 tons net register, having two masts, the lower masts being of iron, the top masts of wood. The steel wire rigging (served over) is carried to within about 3ft. of the trucks, but there is no special lightning conductor fitted. Captain Woodcock reports the following incident on May 16, in latitude 28·12 N., longitude 70·50 E.: 'The morning was squally, with rain, and thunder, and lightning. About half-past seven the storm seemed to have passed over, and the weather showed signs of clearing up, when, after a considerable interval, there was a very vivid flash of lightning, accompanied by a violent explosion by the rail, near the starboard fore rigging, which seemed as if something had exploded and scattered sparks and fire over the ship. The foretopmast was splintered near the spire, and some service torn off the topgallant backstay. The shock also affected the compasses; that on the upper bridge was deflected from N. 72 W. to N. 45 W., and remained for a short time that way. The wheelhouse compass, which had previously shown W.N.W., now showed E.S.E., and the compass on the poop was considerably affected also. After trying another compass card in the wheelhouse, found the card was not affected, but the shock had changed the magnetism of the ship so much that it r[illegible] end. The westerly deviation of the upper bridge compass was later on found to be increased 9deg. W. to 19deg. W. on the course steered (N. 72deg. W.). At 4 p.m. swung the ship completely round, and found the errors of the compasses very much altered; the deviation on the north was altered from 6deg. W. to 27deg. W. It was found after the ship was turned round that the wheelhouse compass had regained some of its original power, as the north point again pointed somewhere towards the north. Since the occurrence the compasses have never regained their original errors, and the magnets have had to be moved and some reversed, to reduce the errors and make them easier to be applied.'"

Overhead Wires.—On Wednesday afternoon, Mr. Courtenay Boyle, on behalf of the Board of Trade, received a deputation from the Electrical Section of the London Chamber of Commerce with reference to proposed alterations in the clauses of the Overhead Wires Bill. The deputation was introduced by Sir Vincent Barrington. Major Flood Page explained that the Electrical Section had several objections to make to certain clauses of the Bill for the benefit of the telephone industry, which he hoped would be taken into consideration by the Board. Mr. Courtenay Boyle said that it was a little out of order to receive deputations after public discussion had taken place, but as the question was still open the Board had agreed to consider, and had already embodied, alterations which would cover many of the objections. The clauses were then gone into seriatim. The chief alterations embodied were that the companies should mark routes of wires and positions on a map, 25in. to the mile, supplied by the County Council, six months being allowed instead of three; new wires were to be marked one month after running instead of 14 days beforehand—a great concession; clause 3, with reference to previous consent for fixing poles, is taken out altogether; 6ft. is to be the height above roofs instead of 7ft., and the clause is to refer to future wires only; the limit of 140 yards span is altered to no limit, provided consent of Council and local authority be obtained; the clause with reference to angle of crossing of street comes out; modifications of the factor of safety clause are allowed; the wind pressure calculated for to be 35lb. per square foot instead of 50lb.; the company owning the support is to be responsible for wires and attachments to that support; clause 11 is struck out; the clause with reference to weight and diameter of wire is altered to read that the wire shall not exceed 1lb. per lineal foot, instead of yard, and no limitation is given as to diameter; the clause re prevention of oxidation of support is suitably modified; the clause about connection to earth is struck out; clause 19, with reference to disused supports, reads that no support is to be left after it has ceased to be of use "unless the company intend to put it into use again"—an enormous difference to the company. The chief objection, however, was to the right of compulsory access to houses by inspectors. Major Flood Page said that wayleaves were difficult enough to obtain now, and if a wayleave carried compulsory power to inspect, householders would simply refuse to grant wayleaves at all, and the telephone industry would enormously suffer. The danger was problematical—out of 700,000 accidents only two had been traced to overhead wires. He urged that the companies should only be asked to do their best to obtain leave of access. Mr. Courtenay Boyle said the clause provided for access at "reasonable" time after "reasonable" notice. The question had been fully discussed, and he could hold out small hope of the Board's altering the clause. He would, however, bring it before their notice. The deputation thanked him and then withdrew.

CENTRAL STATION AT OXFORD.

On Saturday, June 18, the formal ceremony of turning on the current by the Mayor of Oxford took place. A large and influential company were gathered together to witness the ceremony. Before, however, saying anything more of this festal gathering, it may be well to supply our readers with a slight history of the undertaking and a description of the equipment of the station.

FIG. 1. - Oxford Electric Company's Station at Osney.

The Electric Installation and Maintenance Company obtained two provisional orders at the same time --one for Oxford and one for the Crystal Palace district. Last August the company was reconstructed; the business of the original company being restricted to the carrying out of the Crystal Palace District order, while the Electric Construction Corporation took over the Oxford order, and have carried out the work, with the intention, however, of ultimately transferring it to a local company, formed and

FIG. 2. -Dynamo Room.—Osney Station.

entitled, "The Oxford Electric Company." An application was therefore made to the Board of Trade to transfer the provisional order, which application has been duly granted by Electric Lighting Order Confirmation Bill (No. 4). In the meantime, as Mr. J. Irving Courtenay (chairman of the Oxford Company) explained at the statutory meeting, the Oxford Company made an agreement with the Electric Construction Corporation to provide for the construction of a fully equipped generating station for the supply of electricity, together with all the necessary street works, mains, transformers, and storage batteries for the supply of the area with which it was first proposed to deal. This area comprises High street, Cornmarket-street, Broad-street, Magdalen street (from the corner of Beaumont-street to Cornmarket-street), and Catherine-street. In this area there are 12 colleges, 39 public buildings, and 337 shops, offices, and private houses. Provision was made in the contract for a supply sufficient for about 15,000 lamps. The system proposed was described as a moderate high-pressure continuous current of 1,000 volts, with continuous current transformers to convert to 100 volts, and secondary batteries to supply current to lamps during the hours of minimum demand, so that during this period the generating station might be entirely shut down. The high pressure current goes by underground mains to the distributing stations, the principal one being in Broad-street. Under this contract the Electric Construction Corporation entered into a sub-contract with Mr. Kingerlee, a well-known local builder and contractor, for the erection of the necessary buildings at Osney, the site being close to the water's edge and extremely convenient. The whole of the works have been carried out by the Electric Construction Corporation from the designs of Mr. Thomas Parker, who has had, as resident engineer, a most efficient assistant in Mr. W. H. MacLean, under whose immediate superintendence the whole plant has been fitted up. The works, as completed and opened on June 18, include the general-

ing station at Osney, where there is a battery of accumulators and motor-dynamo, in addition to the generating plant, and sub-stations have been established at 45, Broad-street, where there is a larger battery of accumulators and motor-dynamos, the other sub-stations being in King street and in Queen street, where also motor dynamos are fixed

Coming now to a description of the station and its equipment, Fig. 1, prepared from a photograph, shows the river front of the building, Fig. 2 shows the engine and dynamo-room. This room is furthest from the river,

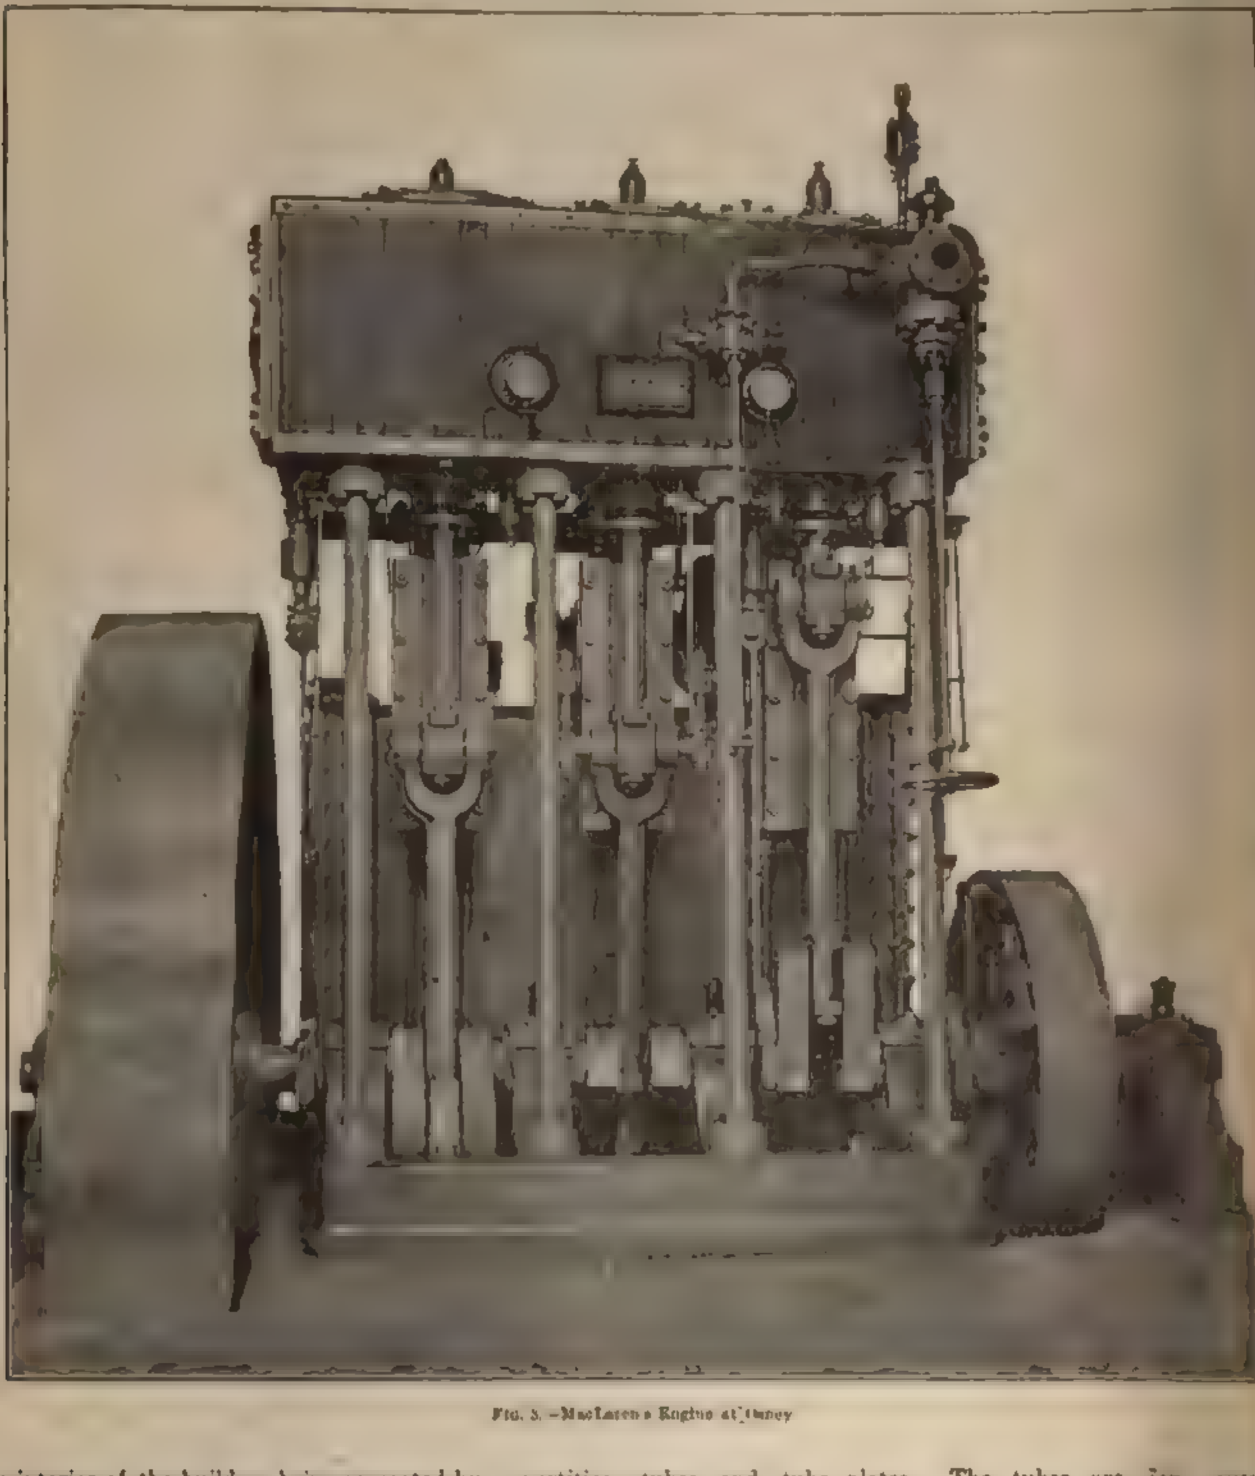

Fig. 3.—MacLaren's Engine at Osney

the interior of the building being separated by a partition wall seen behind the engines. The half of the building nearest the river front is devoted to boiler space, so that the fuel has to be moved through the shortest possible distance. The boilers and engines have been constructed by Messrs. J. and H. McLaren, of Leeds. The boilers are of the multitubular locomotive type, and are made of Siemens steel throughout, and with them is used a Green's economiser. The donkey pump is by Worthington.

The engines, Fig. 3, are of the vertical triple expansion with high pressure and intermediate cylinders d with steam at boiler pressure, and drained through a M'Dougall steam-trap into the hot-well The low pressure cylinder is not jacketed. The M'Laren automatic expansion governor works direct on to the high pressure slide valve, which is not balanced in any way. The governor being self locking is not affected by any friction on the slide valve. The steady running of the engines under very varying loads proves this governor to be all that could be desired, and being keyed on the crankshaft there is no fear of accident through the governor belt breaking or coming off The surface condenser is fitted with brass tubes and tube plates. The tubes are ⅝in. out diameter; cooling surface, 382 square feet; air-pu 11¼in. diameter by 14in. stroke; circulating pump, 10 diameter by 14in stroke; feed pump, 1½in. diameter 14in. stroke; all pumps placed behind the conde and worked by levers from the intermediate en crosshead. Clearances of cylinders are as follows · H pressure cylinder, top 117 cubic inches, bottom 161 di intermediate cylinder, top 237 cubic inches, bottom ditto; low pressure cylinder, top 482 cubic inches, bo 574 ditto, crankshaft, forged steel, 5½in. diameter, c pins 5½in. diameter, each bearing 9in. long, total leng

bearing surface of crankshaft 54in.; eccentric straps, wrought iron, lined with cast iron, eccentrics cast iron, all spindles $1\frac{3}{8}$in diameter, all wearing surfaces of ample area. The engines are very massive and substantial for the power

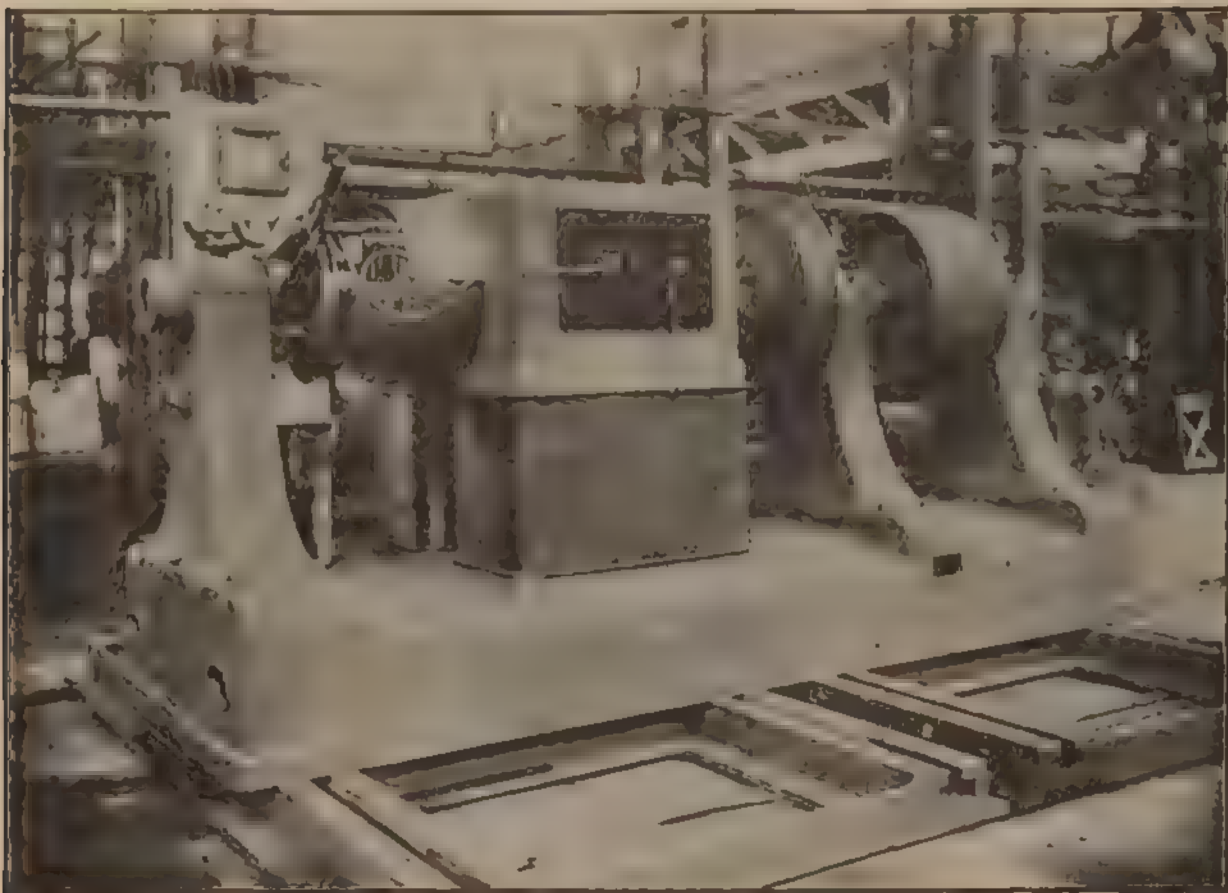

FIG. 4. Dynamo at Oxney.

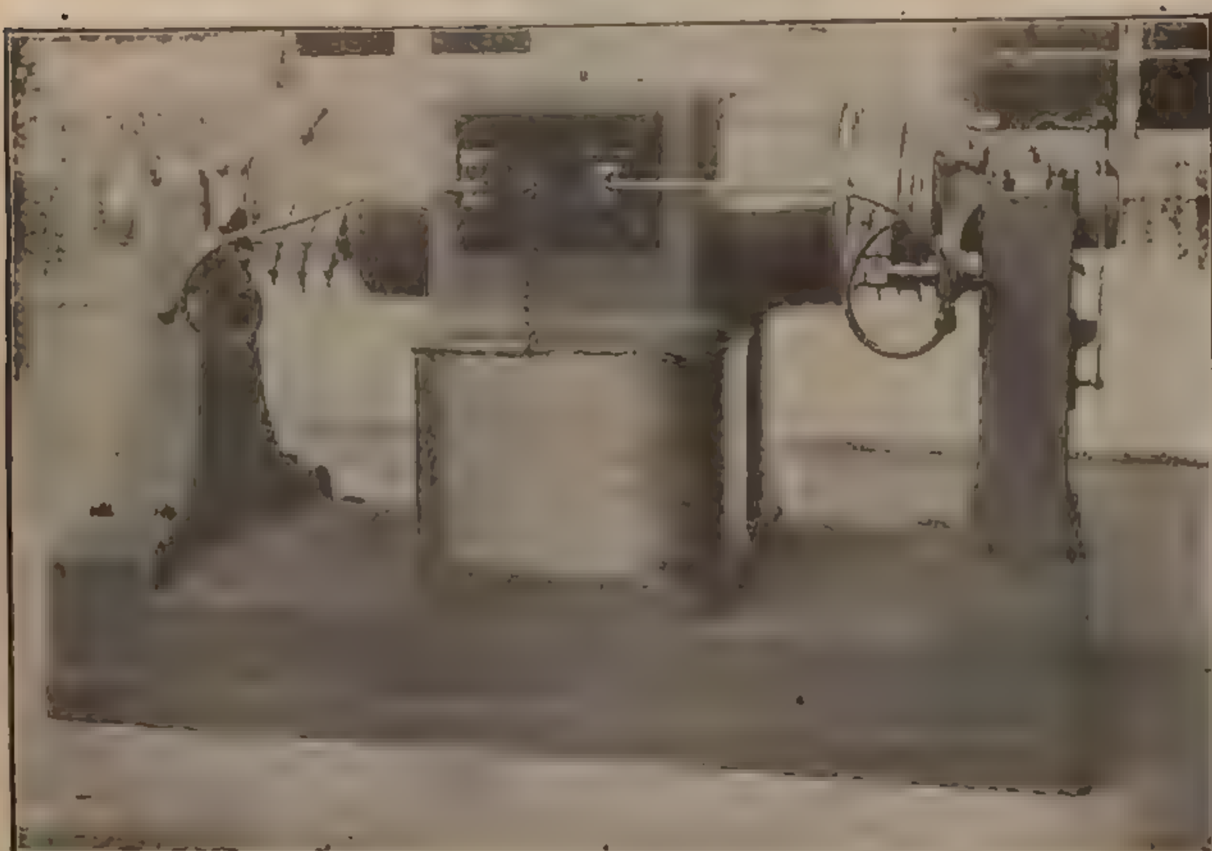

FIG. 5. Motor Dynamo at Oxney.

eccentric rod joints case-hardened and adjustable; piston-rods of steel, $2\frac{1}{4}$in. diameter; crossheads wrought iron, fitted with cast-iron slippers 96 square inches area, valve-

they require to develop. No expense has been spared in making these engines, so that it is expected they will work economically for many years without much cost for repairs

or tendency to breakdown. In addition to the foregoing information the builders have given the results of tests of these engines :

Type of engine	Inverted triple expansion	
Size of cylinders, h.p. 9in., m p. 14·25in. l p. 22·5in. by 24in. stroke		
Type of boiler	Locomotive	
Heating surface, fire box	116 sq. ft.	
Heating surface, tubes	764 sq. ft.	
Heating surface, total	880 sq. ft.	
Number of tubes	105	
Dimensions of tubes	11ft. 1½in. by 2¼in. outside diameter	
Material of tubes	Steel	
Dates of trial	19th Jan.	21st Jan.
Jackets	Not used.	Used
Duration of trial	245min.	240min.

Coal per square foot of grate area per hour	15·00	12·8	
Water evaporated per lb. of coal	10·18	10·11

The engines drive the dynamos by means of link leather belts, with centre steel links. The dynamos, Fig. 4, are direct current, giving an output of 1,080 volts, 80 amperes, at 400 revolutions The dynamos are fitted with extra bearing on the outside of the pulley, and are separately excited by three small continuous-current Elwell Parker dynamos, driven by rope gear from a pulley on the main shaft of the dynamos, as shown in the illustrations. The exciters are arranged to give 135 volts, so as to charge the accumulators used for lighting the central station. The pressure of the main dynamos may be regulated from 1,100

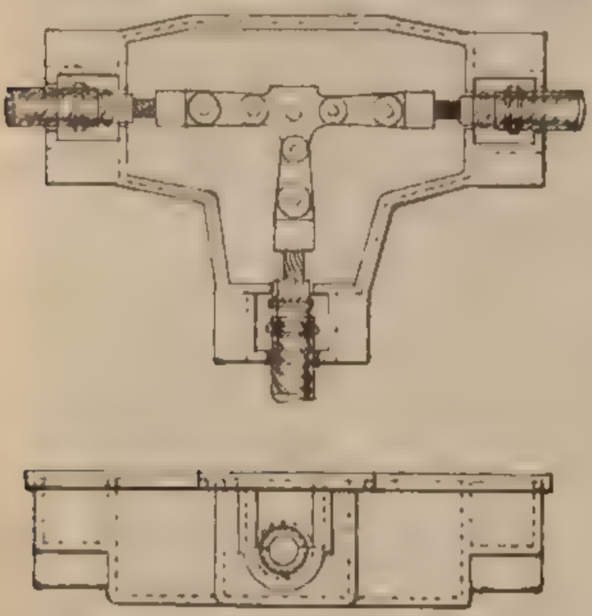

FIG. 10.—Disconnecting Box with Three Links.

volts at full load to 1,000 volts at light load, by means of resistances placed in circuit with the exciters. Each dynamo has in circuit an automatic cut out, which protects the dynamo in the event of any short circuit or excessive current. The cut-out is reset by hand. The main dynamos are coupled in parallel on to main omnibus bars, from which current is transmitted by means of two pairs of vulcanised cables drawn in iron pipes to the central switchboard in Broad-street, where another pair of omnibus bars receive the current. Fig. 5 shows the motor-dynamo, one of which is in the central station and others at the sub-stations. These motor-dynamos are all of the self starting type, and are similar to the one described in the machine department at the Crystal Palace. Briefly speaking, the machine is a double one, having two sets of armature windings, one receiving current from the generating high pressure dynamo and acting as a motor driving the other, which thus acts as a generator to feed the low-pressure supply, or distributing network.

The cables for the distributing network have been manufactured and laid by Callenders Bitumen, Telegraph, and Waterproof Company, Limited, under the supervision of their resident engineer, Mr. W. Douglas Reid The cables are of two sizes—viz., ½in. section and ¼in section and are of the lead-sheathed and armoured type, Figs. 6, 7, and 8, the armour consisting of two layers of steel tape. The cables are simply laid in a trench under the footway, at a depth of about 18in. They are laid in lengths varying from 150 to 200 yards, and are connected together in cast-iron joint-boxes, with copper connectors, Figs. 9 and 10. The box is then run in solid, with bitumenised wax compound. Disconnecting branch boxes are provided at different points in the network, so that any section or street can be cut out without in any way interrupting the supply to the other portion of the network. House services are laid on when required, the joints to the mains being made in T boxes, with T-copper connectors. These boxes and connectors are so made that the cable has not to be cut. The cable is simply bared down to the copper strand and the connector put on and soldered, and then the box is run in solid with bitumenised wax compound. The small service cables are of two sizes, $^7/_{14}$ and $^{10}/_{16}$, lead-sheathed and armoured.

The arc light cables are also $^7/_{16}$, lead-sheathed and armoured.

(To be continued.)

THE OPENING CEREMONIAL.

Thus far, then, our description of the Oxford central station, which, as we have said, was formally opened on June 18. On that day, at the invitation of the directors, a large company assembled, and at half-past six sat down to dinner, which was laid in the dynamo-room. At the conclusion of the dinner

The **Chairman** (Mr. J. Irving Courtenay) welcomed the guests at that interesting stage of this great enterprise, and in suitable terms gave the loyal toasts.

Mr J. S. Balfour, M P., proposed prosperity to Oxford, pointing out that Oxford belonged to England as a whole in its past, in its present, and in its future; and the ceremony of that evening would show that Oxford, in matters of progress, was keeping fully abreast with the spirit of the times.

The **Mayor of Oxford** (Mr. Ansell) replied, stating that they were blessed with over 20 corporate bodies in Oxford, and, as a rule, corporate bodies were very slow to move in any new path. It might be surprising to some of the guests to know that the gas company - although one of the oldest in England - had not even yet obtained the introduction of its manufactures into the college rooms. He pointed out that in Japan the new illuminant was seen by him during his stay at Kyote the old capital at a new theatre which had just been finished there, and he trusted that as they had a very pretty theatre in Oxford, the management would move with the times and provide it with the electric light. On behalf of the Corporation, he would say that they were animated with one object - to promote the prosperity of the city.

Sir Henry Acland then replied for the University of Oxford. He could not understand why he was called upon to make this reply, but suggested that he had one qualification, that of age, which ought to give him experience. His experience was somewhat curious. When he first came to Oxford, he travelled outside a coach from Exeter. When he returned home he went by rail in 4¼ hours. He had seen the telegraph invented and come into universal use, also the telephone; but there seemed one great want in this city the adoption of the new illuminant.

Mr Louis A. S. Bigge also responded, and then the **Chairman** announced that the Mayor would switch on the light, which was done amid great applause.

Alderman Buckell proposed "Prosperity to the Oxford Electric Company. He was glad to find Oxford in the van in the march of improvement. He thought the toast was deserving of approval, and the company was deserving of support, and that the light which was brought to their doors should be taken advantage of by every man of enterprise in the city. Referring to the manager (Mr. Offen), he came into Oxford comparatively a stranger, and by his courtesy and perseverance had won hosts of friends.

The **Chairman**, in reply, said he thought it was a subject for congratulation that the works had reached their present complete condition with so few hitches or serious delays of any kind. The fact was that the business of supplying electricity had now passed its experimental stage, and had reached a development that there was little or no practical difficulty in furnishing a city with a supply of electrical energy, which could be used for the purposes of lighting, power, or traction, or even of cooking, of which they had had illustrations presented to them that evening. The finishing of the buildings, and the fitting and installing of the plant and machinery, not only in the building in which they were, but in the sub-stations, so that the supply of light could now be furnished as promised, was very creditable to Mr. Parker and all those who as members of the staff were in their several departments responsible for this desired result. The extent to which electricity could be made available for the daily use of the people was not, he thought, sufficiently appreciated in this country, and he thought it was a mistake to suppose even in the present comparatively early development of this new industry that it was an expensive luxury It would be found in the long run, where it was intelligently used, and when all the circumstances were taken into consideration, to be as nearly economical a form of illumination as anything else, and when compared with gas it had undoubtedly marked advantages if they took into consideration the questions of health and convenience, and above all of safety He

believed there was an immense future for it in the direction of motive power. But in a city like Oxford the employment of the electric light was a matter of supreme importance. The Bodleian Library could now be used in the evening by the employment of this absolutely safe light, and also in foggy weather, a light which would not injure the books or any works of art. Then the Sheldonian Theatre could be utilised by night as well as in the daytime for the giving of concerts, which now had to be given only during daylight. There were many other developments which he might easily adduce, such as in the launches they had seen that day on the River Thames, and nothing could be better than that station on its banks for the supply of the motive power. They had to thank the Corporation for arranging with the company to test the lighting of the streets by electricity. Well lighted streets were a necessity of modern times, and although they commenced with a few lamps he hoped that within a short time the city of Oxford would be able to boast of the best public lighting in the kingdom. The enterprise had been carried out without any public subscription of capital, but with the ultimate intention of giving the inhabitants an opportunity of acquiring it either as a Corporation property or as a private local enterprise. He thought all enterprises of this kind should be local undertakings, and there was every reason why the supplying of electricity should afford a profitable means of investing capital when conducted under sound local business management, aided by experts who possess special knowledge of the subject. He was sorry to say that many of their friends had had to go away and catch their trains, among them Mr. Parker, their chief engineer, who had been coupled to respond to the toast, but he had put into his hands the remarks which he had proposed to make, and with their permission he would read them.

Mr. Parker referred in detail to the choice of that site for the works, which was a suitable one for many reasons. The system was required to be continuous current with a view to having a reserve of power in accumulation, and the site being a considerable distance from the provisional area it was necessary on the score of economy, and to make use of the station for reaching over the whole area of probable lighting, to use high-tension currents. The tension selected was 1,000 volts, with a range of sufficient increase to manipulate the voltage as the load was taken on and off the mains, varying to 10 per cent., so that the voltage at the station would at no time exceed 1,100 volts, whilst the voltage on the network from which the consumers' current was taken would be in all cases 100 volts, varying within the limits allowed by the Board of Trade. The system as a whole had been passed by the Board of Trade. They had secured a very high efficiency and reliability in the transformers, and had carefully worked out and patented means of handling them with the same precision and attention a mile away from the station as though they were in the station and under the eye and care of the attendant, thereby securing the least cost of superintendence of the system. This power of the management of the transformers enabled them to manipulate with continuous currents and a very high economy a large area of supply from one single station, therefore the station might be increased to the full requirements of the town, as was now carried out in the ordinary gas supply. The transformers were run in parallel with the accumulators, or run independently upon the consumers network by themselves. The economy of the transformers being 92 per cent. at full load, and not falling below 82 per cent. at one third load, and being at all times under the command of the attendant in the station where the manipulation of the whole system was carried out, the attendant was enabled to cut out or put in any of the transformers where the voltage indicated current was required, thereby securing that no energy was wasted at any part of the system, and that the whole system or any part of it was with the highest possible efficiency, the batteries situated in the centre of the provisional district at the controlling station being sufficient to carry out the lighting at any point of the district for the short hours, thereby enabling the central station to cease running when the batteries were capable of doing the lighting. The buildings had been put down with a careful view to the extension of the station up to a capacity of 30,000 running lights, and he was pleased to be able to pay their architect, Mr. Brevitt, of Wolverhampton, and the builder, Mr. Kingerlee, of Oxford, a compliment upon their design, cost, and execution. The boilers were chosen to give the highest evaporative efficiency, and the engines were slow speed, triple expansion, condensing, indicating 120 h.p., and of the highest class of manufacture. The dynamos run at a speed of 400 revolutions, and are well over their normal work, so that at any pinch they might be able to stand the higher portion of the supply curve without risk if it exceeded the estimated output by 25 per cent. In the electrical part all had been constructed with the greatest care to durability and efficiency, and for the development necessary to meet the demands of extension, which they confidently anticipated, so that they did not claim that the station, or means, or arrangement was designed to do its best work upon the present capacity, but whilst it would do its work upon the capacity as now arranged with high economy, it would be much more economical, and show its greater advantages as the station became extended. He estimated it no small honour to have had the opportunity of laying out and putting to work the lighting station of Oxford, and felt sure that the Oxford people would not be slow to appreciate the advantages of the electric light, both in its aspect as an improver of healthy conditions in their dwellings, reducing fire risk, and in its cleanliness and adaptability to artistic effect.

Mr. Henry Mance proposed the health of "The Visitors," to which **Mr. Soutter** replied.

Councillor James proposed the health of "The Chairman," who replied, and the proceedings terminated.

TESTS OF TWO 6,500 WATT WESTINGHOUSE TRANSFORMERS.

Before giving any results of the tests I have made with your transformers, it will be well to explain the methods of experiment adopted.

The instantaneous value at any epoch in the period of the difference of potential between any two points of a circuit in which the potential difference is varied periodically, is made effective on the measuring instrument by means of a rotating contact maker attached to the shaft of the alternate-current generator. This contact maker was constructed for the King's College laboratory by Messrs. Siemens Bros.; it makes contact once in each revolution for a period of about ½deg., and breaks it for the rest of the revolution. It is entirely insulated, and so can be connected to any part of any circuit. The position of the contact can be varied, and the variations be read off on a graduated circle of 3½in. diameter divided into degrees, and by estimation the variation can be read to one-tenth of a degree.

The two points between which it is desired to measure a potential difference are connected through the contact maker to a condenser and quadrant electrometer, as shown in Fig. 1, in which A and B are the points the potential difference of which, at a stated epoch, is to be measured, C the revolving contact maker, D the reversing switch of the electrometer, E the condenser, of which the capacity can be varied, F the quadrant electrometer. It is evident that the quadrant electrometer will give a reading proportional to the potential difference of A and B when C makes contact. If there were no leakage, it would at once give this potential. It is to obviate the effect of leakage that the condenser is introduced, and the amount of the effect was determined by varying the condenser: thus, when the condenser had capacity 1, 0·5, and 0·2 microfarads, the reading of the electrometer for a given potential difference of an alternating current at the position in the period of maximum E.M.F. were 138, 136, and 132 respectively. The rate of loss of potential will be proportional to the reciprocal of the capacity, whence we at once infer that the true reading, if insulation were perfect, would be 139½, and hence the readings are always corrected by adding 1 per cent.

When the potential difference was too great for the electrometer it was reduced in any desired ratio by two considerable resistances introduced between the points to be measured in the usual way, Fig. 2.

The potential difference may, of course, be measured in other ways. An ordinary voltmeter may be placed between A and B, in which case it must be standardised with the contact breaker in circuit, and it will depend for its constant on the duration of the contact, which may vary; further, it gives, not the difference of potential at any definite epoch, but the mean difference of the whole time of the contact. The condenser may be used, and its potential measured by discharge through a galvanometer; this is open to the objection that if there be any leakage the result will depend on the time at which the contact is broken by the condenser key in relation to the time at which it was made by the revolving contact maker. Lastly, a Clark cell may be used, by a method which Major Cardew pointed out to me, as shown in Fig. 3, the resistances being adjusted until there is no deflection. This is open to the same objection as the first—namely, that it gives the mean of the potential differences which occur during the contact.

By making use of the first-mentioned method, we have the means of measuring accurately any potential difference at any epoch of the period, and of knowing the epoch.

For these experiments two transformers intended to be identical were available, each transforming between 2,400 and 100 volts. It was most convenient, on account of the resistance available, to couple these transformers up from 100 to 2,400 in the first, or No. 1 transformer, then down from 2,400 to 100 in the second, or No. 2 transformer, and to take up the energy from the second in a non-inductive resistance. The arrangement is shown in Fig. 4.

The obvious way of determining the efficiency of the combination would be to measure at various epochs of a half period the potential differences of the terminals of the machine and the current passing to No. 1 transformer, in like manner at the same epochs to measure either the potential differences or the current passing to the non-inductive resistance, thence to deduce the power supplied to the first transformer and taken from the second. This would be open to certain objections; we are comparing two nearly equal magnitudes, and desire their ratio, the ratio will be affected with the full error arising from an error in the determination of either magnitude, and such errors may be material, as the observations are not simultaneous, and conditions may change between one series of observations and another. These objections are avoided by the method adopted. The current from No. 2 is observed at certain epochs, the difference of currents between No. 2 and No. 1, and the difference of potential difference of No. 2 and No. 1 at the same epochs. These give the currents and potentials of No. 1 at the same epochs as the corresponding determinations of No. 2, and the differences will only be affected with the proportion of error of those differences. For example, suppose the efficiency of the combination were 90 per cent., and the possible error of determination of power 1 per cent., our result might be anything from 88 to 92 per cent. if made in the obvious way, but if made by differences the maximum loss would be 10·1 per cent., and the possible least determination of the efficiency would be 89·8 per cent. The method is essentially similar to the method I described* and subsequently used for testing

* *Proceedings* of the Institute of Civil Engineers, vol. lxxxvii., p. 235, and *Transactions* of the Royal Society, part I., p. 347 (1886.

dynamos. The measurements are made as follows: for difference of potential differences, Fig. 5; for current difference, Fig. 6, where G is a small non-inductive resistance. The two currents will of course slightly disturb each other, but this is readily allowed for in the calculations.

Another method would be to couple them as shown in Fig. 7, G1, G2 being equal non-inductive resistances. This arrangement is quite free from disturbance, but requires two resistances adjusted to exact equality. A single transformer can be tested in he same way, though in this case reliance must be placed upon resistances to reduce the current of the low-potential coil, and to reduce the potential of the high-potential coil in the ratio of the number of windings in the two coils.

The current was throughout generated by a Siemens alternator with 12 magnets, run at a speed between 830 and 840 revolutions per minute, which gives a frequency of 5,000 per minute, or 83 to 84 per second.

The first experiment tried* was with the two transformers coupled, but with No. 2 transformer on open circuit, or on nearly open circuit, for a high resistance for purposes of measurement was interposed between the terminals of the low-resistance coil of No. 2 transformer. The actual results are given in Table I., and are expressed in Curve I. Tables II., III., and IV. give the results for half power, nearly full power, and full power, and the sets of curves of corresponding numbers give the results of the tables. In these tables the first column gives the position of the contact brush in degrees, so that 60 on this scale corresponds with a complete cycle. Three degrees are thus $\frac{1}{83 \cdot 3 \times 20}$ of a second. The second column of No. 1 table is the current in the thick coil of No. 1 transformer, as determined by the difference of potential at the two ends of a non-inductive resistance in which the current passes. The third column is the potential difference of No. 2 transformer, a direct determination. The fourth column is solely for the purpose of determining the square root of the mean of the squares of the third column. The fifth column is a direct determination of the difference of potential of 1 and 2, obtained in the manner explained with reference to Fig. 5. The sixth column is the deduced potential difference of the terminals of the thick wire of No. 1 transformer, being the sum of the third and fifth columns. The seventh column, like the fourth, is merely for the purpose of determining the square root of the mean of the squares of column six, whilst the eighth gives the rate at which power is given out by or received by the pair of transformers.

If the transformers had been exactly equal, the potentials for the two given by Table I. would have been equal, though they would have differed a little in phase, owing to the lines of magnetic induction which pass through the non-magnetic space between the two coils of the transformer.

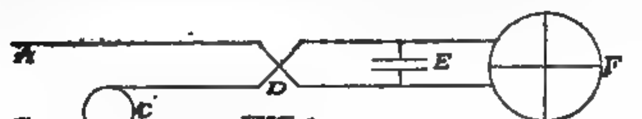

FIG 1

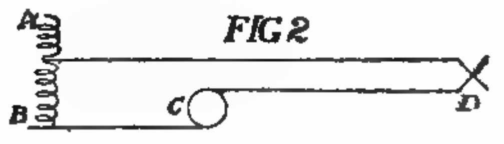

FIG 2

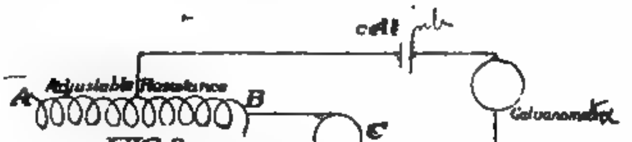

FIG 3

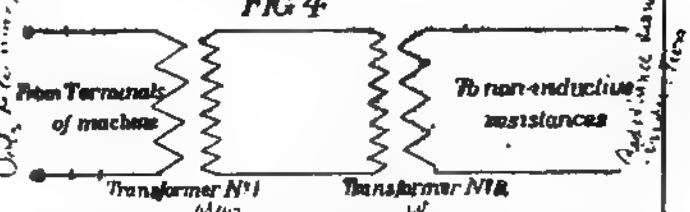
FIG 4



The difference shows that No. 1 transformer has a ratio of transformation slightly greater than No. 2. If we correct the potential of either No. 1 or No. 2, there still remains a difference between them, but this difference will be the greatest about when the potentials are nil. This is due to the lost induction just referred to.† In order to check the conclusion that the two transformers are not precisely equal, they were directly compared as shown in Fig. 8.

FIG 5

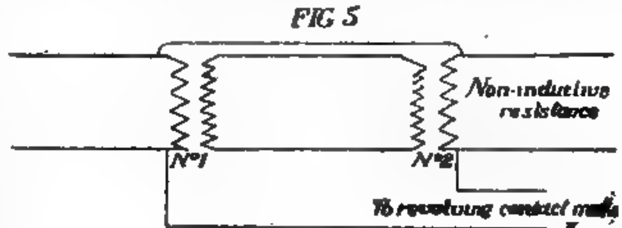

FIG 6

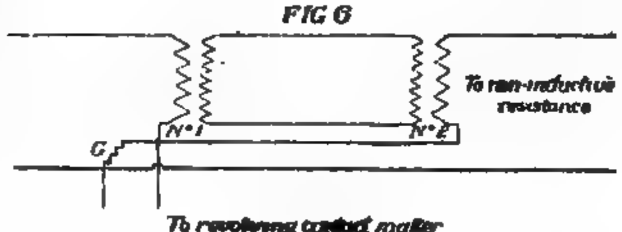

FIG 7

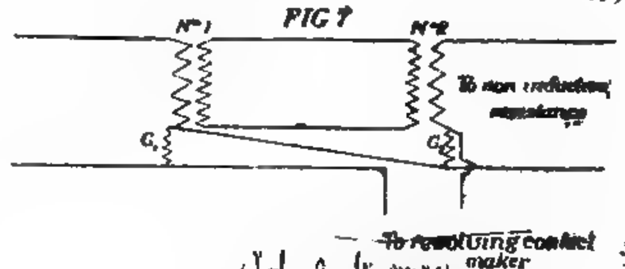

FIG 8

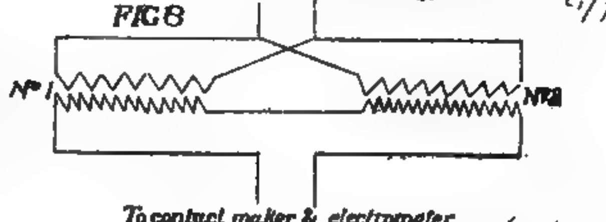

The transformers were coupled parallel, as in Fig. 8, and the difference of potential of the two high-potential coils was measured: the value of its square root of mean square was 12·5 volts, the potential of transformer being 2,400. This does not necessarily imply that the potentials of the two transformers differ by ½ per cent.: it may be largely due to a difference of phase between the two.

The current supplied to the No. 1 transformer is to be accounted for by the currents necessary to magnetise the two transformers, and by the local currents in their cores. To ascertain the former, the curve of magnetisation of one of the transformers was determined by the ballistic galvanometer for nearly the same induction, as in Table I. The changes of current supplied by a battery being

* So far as I know the first discussion of endless magnetic circuit transformers, based on the actual properties of the material, is in a note by myself (*Proc.* Royal Society, vol xlii.). Definite results were obtained by methods generally similar to those now used by Mr. Ryan. The theory of transformers is well set forth by Prof. Fleming.

† Prof. Perry has already pointed out that the effect of such lost induction cannot be entirely neglected even in endless-circuit transformers.

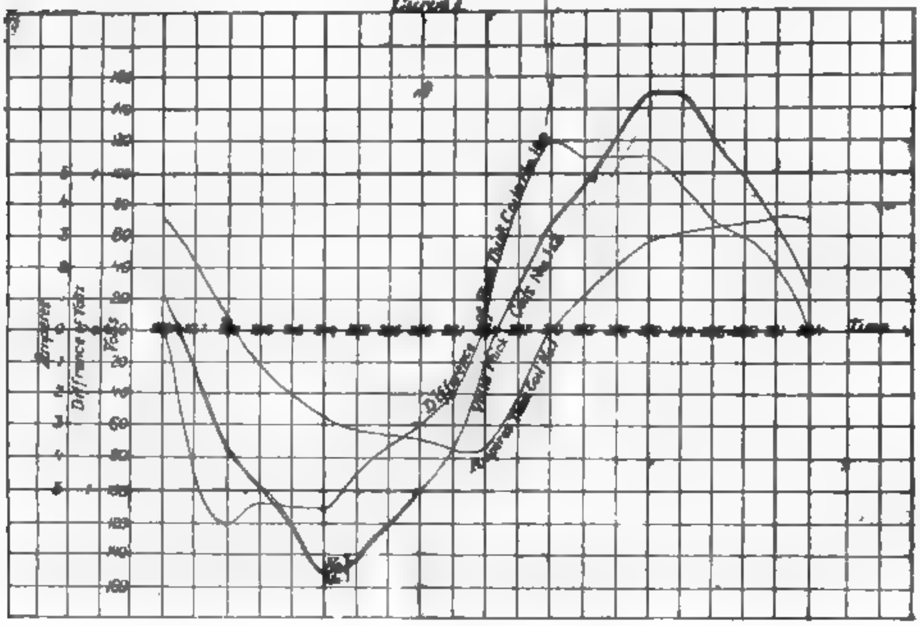
made by a reversing switch, or by suddenly introducing resistance into the primary circuit, and the consequent changes of induction being measured by the galvanometer. The tardiness of change of current in the transformer, due to its self-induction, was sufficiently reduced by using many cells and a considerable resistance. The results are shown in Curve V. for a single transformer. In this curve the abscissæ are the currents in the thin coil of the transformer, divided by 21 to reduce it to the same effect as it would have had if it had been in the thick coil. The ordinates are the inductions as measured by the kick on the galvanometer, but reduced to a scale to make them directly comparable with the volts when the transformer is used with an alternating current.

These results are not given in absolute units. The procedure to determine points on the curve was—first, pass the maximum current corresponding to the point C; next suddenly diminish the current by inserting suitable resistance in the thin-coil circuit, and observe the kick: the drop of ordinate from C to A corresponds to the kick, and the abscissa of A is the current after it has been reduced. Next, reverse the current and observe the kick. The kick corresponds to the further drop of ordinate from A to B. In this manner a series of points are determined on the curve. Curve VI. shows the relation between induction and magnetising current for the pair of transformers as deduced from the experiments with alternating currents set forth in Table I. The ordinates in this curve are the areas of the curve of potentials of Curve I., for the ordinates of this latter curve are the rates at which the induction is changing, whilst the abscissæ are the currents in the thick wire at corresponding times. The points marked 0 in Curve VII. give the remainder after deducting the magnetising current as estimated in Curve V. from the currents of Curve VI.—that is to say, Curve V. is corrected first for the small difference in maximum induction, then corresponding to any induction the current is taken from the curve, it is doubled as there is only one transformer, and the result is deduced from the corresponding current of Curve VI. The differences are the magnetising currents equivalent and opposite in effect to the local currents in the cores. If the local currents were equivalent to a current in a single secondary circuit, the points 0 of Curve VII. ought to have had the form of the full line of Curve VII. drawn through the points +, in which the abscissæ are proportional to the potential difference and the ordinates to the induction. Returning to Table I., we find that the fall of potential difference on open circuit in the whole combination is 0·8 volt, and that the loss of power in magnetising the cores and in local currents is 228·26 watts—that is, a loss for each transformer of 114·13 watts. The total loss of 228 watts may be divided into 126 watts accounted for by the hysteresis, and 102 watts due to local currents.

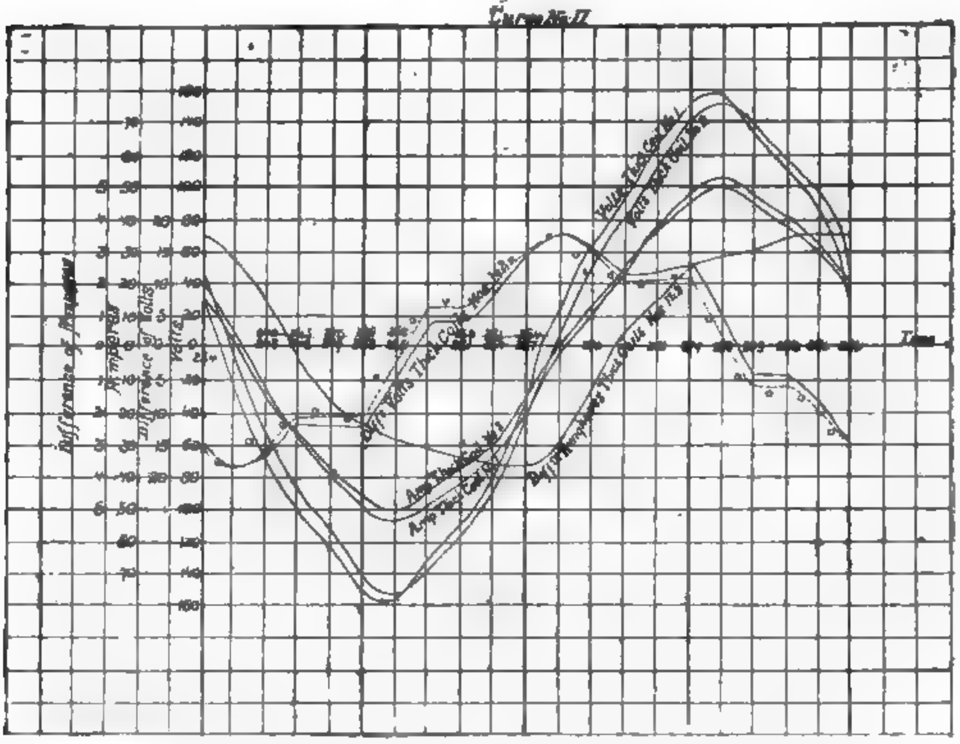
Referring now to Table III. and Curve III., the earlier columns explain themselves, but a word is necessary about the last six columns. The watts supplied to No. 1 are simply the products at each time of the volts at its terminals and the amperes passing through it, similarly to the watts given out by No. 2. We see, firstly, that the efficiency of the whole combination with this load is 93·73 per cent., and hence the efficiency of one transformer, if the losses in the two are equal, may be taken as 96·9 per cent. The fall of potential in the whole combination is 6·1 volts, but the fall with no load is 0·8 volt, hence the variation due to the load with constant potential on the thin coils of No. 1 is 5·3 volts, or, if the fall of potential in the two transformers were equal, which it is not, for a single transformer 2·65 volts. Assuming that the transformers are equal, the power lost in resistance would be expected to be the mean of mean current X, the difference of potential difference, or 215·5 watts. It is in fact 150 watts, as given by multiplying the square of currents by resistances. But the transformers are not exactly equal, and there is the waste magnetic field, both of which will have a small effect on the distribution of loss between the two classes of loss—viz., that by hysteresis and local currents, and that by resistance, but none upon the gross efficiency.

The other tables, II. and IV., are arranged in exactly the

Curve I.

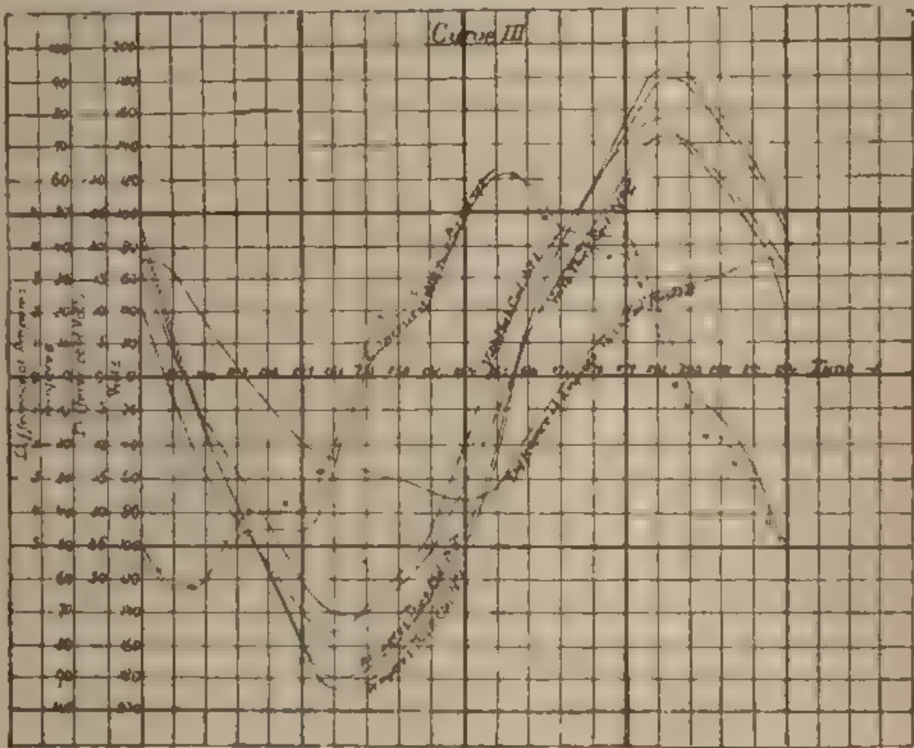


Curve No. II.

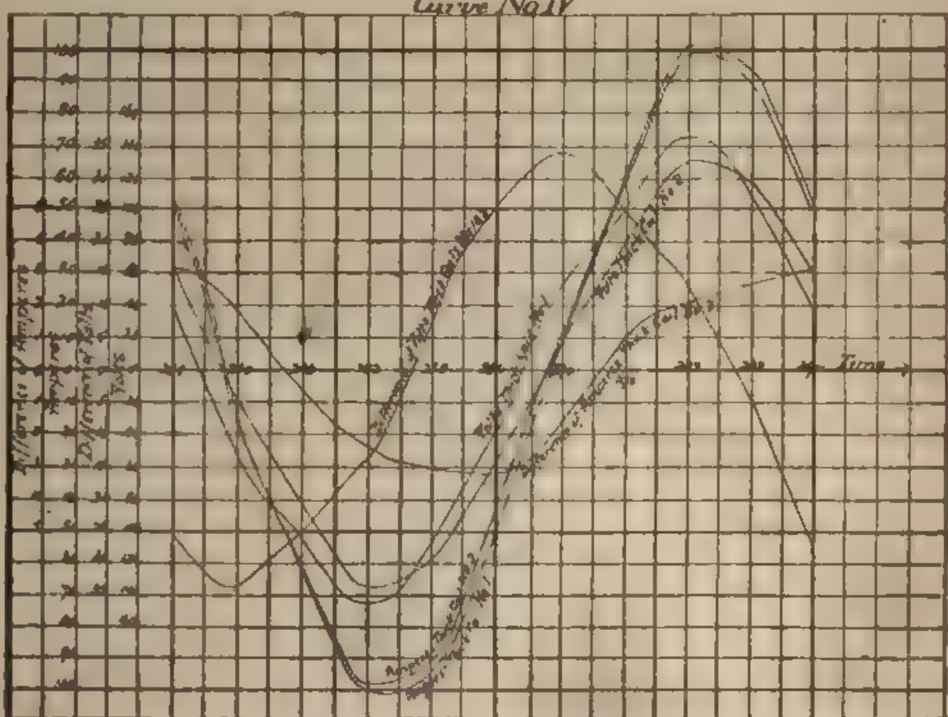


way as Table III., but the number of observations on Table IV. is insufficient to bring out all the peculiarities of the transformers.

It has already been stated, that if the loss of potential due to load in the two transformers be equal, it will amount to 2·65 per cent. The following experiment was tried to ascertain if this loss was equal. The transformers were coupled in series as before. The mean potential difference of the thick wire was measured by Thomson's multicellular and of the thin wires by Thomson's electrostatic voltmeter; the mean of a considerable number of experiments is given in the following table, the load being the same



Curve No IV



as in Table III., and the results being corrected to the same potential of the thin wire.

No.	Full load.		Open circuit.	
	Thomson multicellular.	Thomson electrostatic.	Thomson multicellular.	Thomson electrostatic.
1	2,380	99·8	2,380	99·0
2	2,380	94·2	2,380	96·2

This shows that of a total drop of 4·8 volts, 2·8 volts occurred in No. 1, and two in No. 2. There is no doubt of the fact that the drop is greater in No. 1 than in No. 2, which is connected with the waste field between the two coils. Of course these transformers are intended to work exactly as No. 2 is working, in which case the drop from no load to nearly full load, as shown by this experiment, is 2·0 volts. The way in which this waste field causes inequality of drop of potential in the two transformers, coupled as in my experiments, is very worthy of careful consideration. The waste field is proportional to the current in the transformers, or better, to the mean of the two currents in ampere turns. The E.M.F. due to this waste field will be proportional to rate of change of the current. If the current were expressed by a simply harmonic curve, the E.M.F. due to the waste field would also be a simple harmonic curve differing in phase by $\frac{\pi}{2}$. The curve of potentials is roughly in the same phase as the curve of current. Let A be the amplitude of potential difference of No. 2 transformer, B the amplitude of difference of potential difference in No. 2, or the potential difference of the thin wire divided by 24, $2b$ will be very nearly the amplitude of difference of potential difference between the thick wires of Nos. 1 and 2. The ratios of potentials in No. 1 and No. 2 will then be $\frac{\sqrt{a^2+4b^2}}{\sqrt{a^2+b^2}}$ and $\sqrt{\frac{a^2+b^2}{a}}$, or $1+\frac{3b^2}{2a^2}$ and $1+\frac{b^2}{2a^2}$, or the drop in the first from this cause is three times

as great as in the second transformer. We shall return to the waste field immediately. Putting aside harmonic curves, and returning to the facts as they are, the following Table V. gives, first, half the difference of potential difference taken from Table III.—that is, at each instant the drop of potential in No. 2; secondly, the volts of the thin wire of No. 2 reduced for number of convolutions—this is, of course, the mean of potential difference between 1 and 2; lastly, the squares of these volts. From this we see a mean square 100·8, showing the drop in No. 2 to be 2·6 volts out of a total drop of 6·1, and the remainder 3·5, the drop in No. 1. Diminishing these results by 0·4, the half of 0·8, the fall observed with no load, the actual losses from no load to nearly full load will be 2·2 and 3·1.

Turn now to the last column of Table III. This gives the difference of potential differences corrected for the loss of volts by

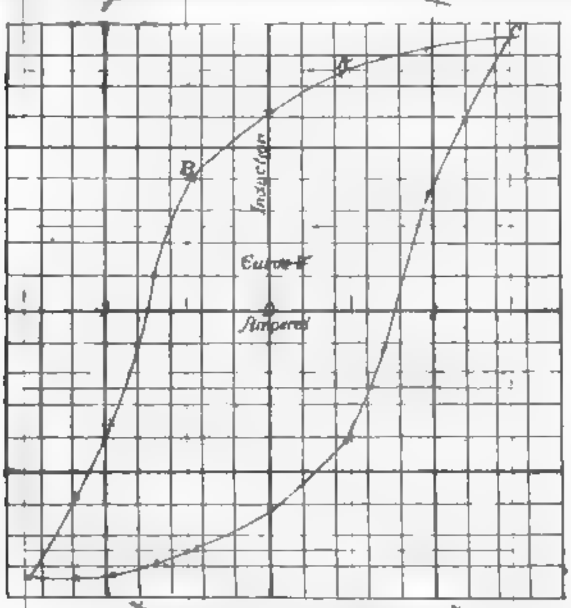
268½	271½	274½	277½	280½	283½	286½	289½	292½	—
30·7	24·2	19·2	18·5	13·9	1·7	−9·3	−12·7	−21·7	−28·1

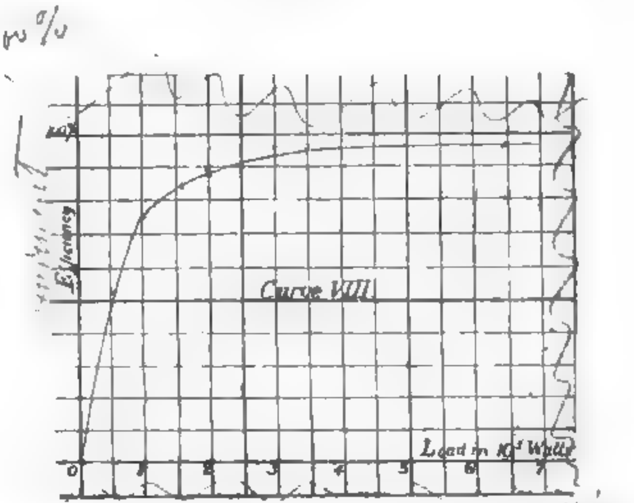
which happens to come to a scale which can be at once plotted. The points marked 0 are the points of the curve corresponding with the above rates. The agreement of the points with the curve is remarkably close. This exhibits very completely the effect of waste magnetic field in this transformer.

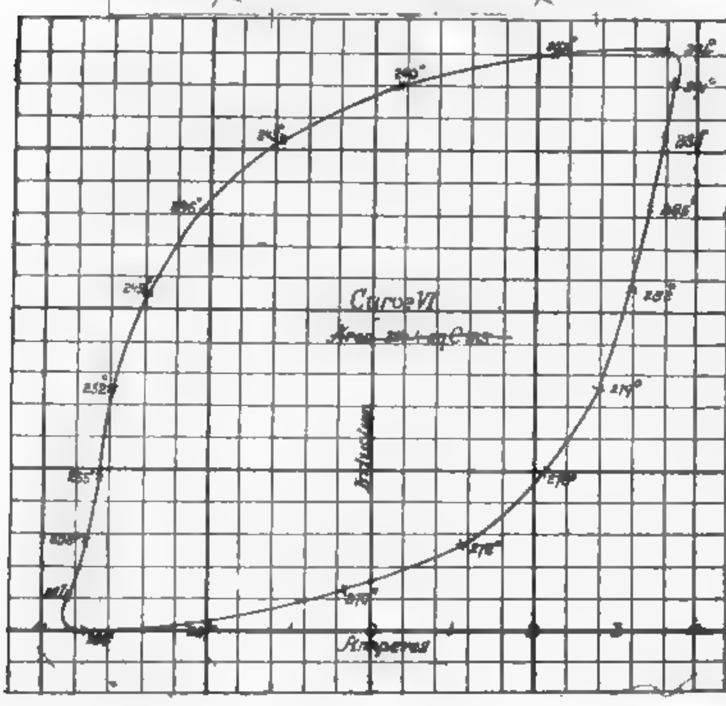
For half power as taken from Table II. the rates are as follows:

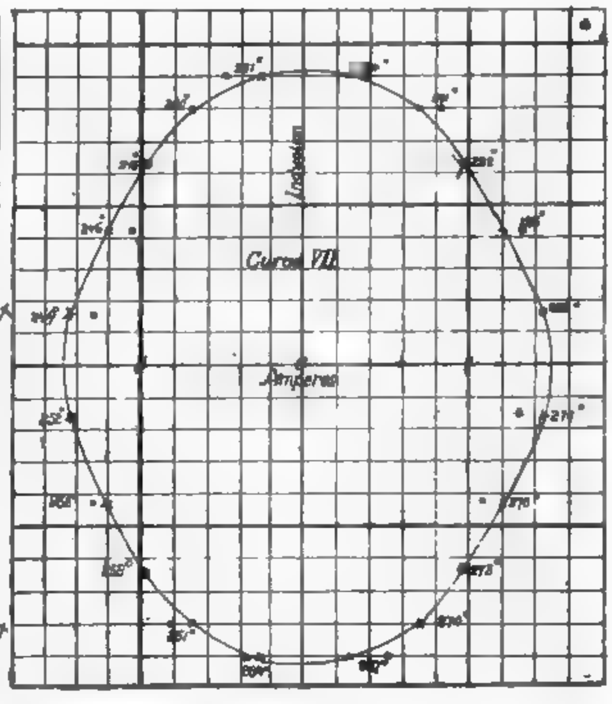
268½	271½	274½	277½	280½	283½	286½	289½	292½	295½
14·6	11·5	9·4	10·6	4·4	−4·6	−7·2	−7·5	−13·6	−17·6

and in the same way in Curve II. the dotted curve represents the difference of E.M.F. corrected for resistance, and the points correspond with the above rates.









resistance. It is shown on the dotted curve, III.; this curve presents one or two peculiar features.

TABLE V.

Half difference of potential difference.	Volts of high-potential coil divided by 24.	Squares of Volts.
15·6	−5·0	25·0
[redacted]	41·3	1706·0
11·3	74·3	[redacted]
[redacted]	102·6	10530·0
11·1	131·3	17240·0
5·5	147·1	21640·0
− 1·1	137·0	18770·0
− 3·1	119·3	14230·0
− 5·9	95·1	9040·0
−12·1	53·4	2850·0

Square root of mean square = 100·8.

It should be possible to infer the form of this curve from the curve of current. The rates at which the mean current is changing are as follows.

Curve VIII. gives the efficiencies in terms of the load. This curve is the hyperbola

$$x - \frac{(A + Bx + Cx^2)}{X}$$

Efficiency = 100.

Where A = 228, the loss by hysteresis;
B = ·005 and mainly depends upon the waste field;
C = ·0000035 and is mainly the loss by resistance;
X = Load in watts.

To sum up, I find that the efficiency of the transformer at full load would be 96·9 per cent., at half load 96 per cent., at quarter load 94·7 per cent. The magnetising current of the transformer amounts to 114 watts, or 1·75 per cent. The drop of potential from no load to full load is between 2 and 2·2 per cent.

In conclusion, I wish to express my thanks to Mr. Wilson, of King's College. This gentleman carried out the experiments under my direction, and made nearly all the numerical calculations, and drew most of the curves for me.

Dated this 31st day of May, 1892. (Signed) J. HOPKINSON.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Dr. J. Hopkinson, Dr. E. Hopkinson, Mr. William J. Hammer, Mr. Alfred R. Bennett, and Mr. Emile Garcke.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

THE TRAMWAYS INSTITUTE.

Perhaps this issue will be looked upon by some readers as too much about tramways, but in this direction Englishmen need shaking up. Hitherto tramway work has been somewhat of a prosaic character—by that we intend to indicate the prevailing custom to ignore the immense possibilities of electricity for this work. But there are indications of a better time even in this horse-mule-steam beridden land. At the general meeting of the Tramways Institute, held last Tuesday, three of the papers were wholly devoted to electrical subjects, one was common to all kinds of traction, and the remaining one was about an oil engine. With the exception of the latter we give a full report of these papers, and trust that it may prove the forerunner of many future reports dealing with the application of electricity to tramways. Although the progress in this country has been slow, we can boast of the biggest practical application in the City and South London Railway, and the successful working of this line has led to the promotion of various lines to be worked electrically. Liverpool also is to have its overhead electric railway, but we desire to chronicle progress in tramways pure and simple. One great reason why more has not been done was given by the president of the institute, Mr. Carruthers Wain—that the required capital was not forthcoming. Tramway work has not been so financially successful as to easily induce capitalists to subscribe money for new departures, though the experience in America should indicate that improvement pays. Mr. Frank J. Sprague, in his inaugural address to the American Institute of Electrical Engineers, dealt with coming developments of electric railways, and, among other things, said: "Electric street railways are no longer experimental, nor is their success problematical. Their history for the past five years is that of an almost unequalled development. Almost within a decade has occurred the first working of a practical electrical railway. In a third of that period there have been put in operation or are under contract more than 450 roads, equipped with nearly 6,000 cars, over 10,000 motors, and with over 3,000 miles of track. There is made a daily mileage of not less than 700,000 miles, and over a billion passengers are carried annually. . . . Thirty thousand horses in a single year have been relieved from the slavery of street-car propulsion; stables are disappearing and streets becoming cleaner; luxurious cars are running on smooth, well-built, and rigid road-beds. Dividends have been increased, expenses reduced, investments enlarged, the unproductive have become productive, the impossible possible. Land values have been increased, habitable limits extended, houses erected, and time saved." That is what is said of electrical tramways in America. In England the president of the institute tells us that some 200 miles of tramways have been authorised by Parliament, and that, to obtain this authorisation, have been proved to be wanted, but have not been constructed because capital could not be obtained. He also heard that the Blackpool electric tramway was likely to come to an end, not because it was unsuc-

cessful, but because the wisdom of the local authorities was against granting a renewal of the lease. On the other hand, there is hope that the line at Leeds may be extended, that Bradford will take up the work, and within two or three months that the South Staffordshire lines will be opened. These are with overhead conductors, and, although not exactly on the same system as the Leeds line, are far more cheaply constructed than with underground conductors. To us one of the most potent factors compelling sooner or later the adoption of electricity, or some other suitable agent, is the relief of horses from tramway slavery. It is to the members of the Tramways Institute we must look for action. They know the difficulties they now have to contend with, and have the responsibility of procuring a dividend for the shareholders upon their shoulders. Once convince them that increased revenue will come from the adoption of the new method, they will aim at its introduction as their means allow; and when equipping new lines will endeavour to carry out the system that seems likely to be the most profitable.

CORRESPONDENCE.

"One man's word is no man's word.
Justice needs that both be heard."

TUESDAY NIGHT'S THUNDERSTORM.

SIR,—The storm of to-night has been a very severe one, and the lightning has been especially vivid. One flash was very noticeable in the neighbourhood of Leyton just before 9 o'clock. It was a vertical flash from clouds to earth, and its path was almost straight (of course it was of a zigzag form, but the main direction was straight). This left behind it a stream of golden sparks which gradually died out, resembling somewhat a rocket. This flash was noticed by several, and the stream of sparks was specially commented upon.

There were numerous other flashes, some representing chains, others tridents, others were semicircular and all manner of shapes. The colour, too, was very noticeable, some almost white, others amber, some violet.—Yours, etc.,

WILLIAM B. CLARKE.

2, Mortimer-villas, Wingfield road,
Walthamstow, 28th June, 1892.

[We ourselves noticed the flashing between the raindrops, during this thunderstorm, in a London street.—ED. *E. E.*]

OUR PORTRAITS.

Hopkinson, Dr. John, is the eldest son of Mr. Alderman Hopkinson, of Manchester, and was born in the year 1849. His mother is a daughter of the late John Dewhurst, of Skipton. His brother Alfred is Queen's Counsel. His education commenced at Lindow-grove School, and was afterwards carried on at Queenswood College, but he left there at the early age of 15½ to enter Owens College, Manchester, where he remained until he was 18, when he entered Trinity College, Cambridge. In the year 1870 he graduated as Doctor of Science in two branches in the University of London, taking as his subjects Pure and Applied Mathematics and Light, Sound and Heat, under the original regulations for that degree. In the following year he graduated at Cambridge as Senior Wrangler and First Smith's Prizeman. These two honours have not very often been obtained by the same man, as the Smith's prize examination is essentially a test of mathematical creative power, or capacity for original work; while the mathematical tripos has always been rather to test a man's capacity of assimilating, and reproducing with accuracy and rapidity, the work of others. By obtaining the first place in both examinations, Dr. Hopkinson therefore showed that both his receptive and creative mathematical powers were of a very high order, and this early promise has been amply fulfilled throughout his subsequent career. It is a fact not unworthy of notice in these days, when the fierceness of competition leads many ardent young students to commit the fatal mistake of neglecting physical exercise, that while at Cambridge Dr. Hopkinson was known as a good oarsman and runner, and that he won a footrace only three weeks before the commencement of his tripos. Early in the year 1872 Dr. Hopkinson accepted the appointment of engineer to Messrs. Chance Bros. and Company's lighthouse works, near Birmingham, at which town he lived until 1878, when he moved to London, and began practice as an engineer on his own account—without, however, giving up his connection with the firm, a connection which still continues, and which has resulted in many improvements in lighthouse work: notably the group flashing apparatus. After his removal to London he very soon became widely known as an expert in patent cases, a branch which still forms an important portion of his practice. In addition to acting as consulting engineer to the Metropolitan Electric Light Company and several other companies, Dr. Hopkinson has carried out a good deal of constructive work. He is now acting as engineer to the Manchester Corporation in lighting the town. From 1877 onwards he contributed a number of able papers to the Royal Society. During the years 1879 and 1880 Dr. Hopkinson read two papers of very exceptional importance on "Electric Lighting" before the Institution of Mechanical Engineers. In the first of these he described a number of experiments made with a Siemens dynamo to determine its efficiency under varying conditions, and mapped out the relations between E.M.F. and current by means of curves, since called "characteristic curves" by M. Marcel Deprez. In the second paper a number of somewhat similar experiments subsequently made by other observers on Siemens and Gramme dynamos, were mapped out in the same way, and the observations were thus made comparable with one another. It also contained descriptions of a method of measuring the brightness of the electric arc, and the determination of the ratio of the potential difference at the ends of the carbons to the current passing. Early in the year 1883 Dr. Hopkinson made some improvements in the Edison dynamo, which proved to be of exceptional importance as forming the basis of subsequent important improvements in dynamo machinery. In the same year he was appointed to deliver before the Institution of Civil Engineers one of a series of lectures on "The Practical Applications of Electricity." His lecture was entitled "Some Points in Electric Lighting," and in addition to a most masterly general exposition of the subject, he developed in it some very important points, such as the possibility of running two or more alternating machines in parallel, and the relations between the efficiency and the dimensions of a dynamo, and he also pointed out that the fact previously observed by Mr. Shoolbred in experimenting with a series-wound Gramme machine, that after a certain current strength had been obtained the E.M.F. began to diminish, could be explained by the approach to magnetic saturation of the iron of the machine. The theory of alternating dynamos was further developed in a paper on "The Theory of Alternating Currents," read before the Society of Telegraph Engineers in 1884. In 1885 and 1889, Dr. Hopkinson read two very important experimental papers before the Royal Society, "On the Magnetisation of Iron," and "On the Magnetic and other Physical Properties of Iron at a High Temperature." Early in 1880 he discovered peculiar properties of an alloy in nickel and iron. In 1886 he read a very important paper before the Royal Society, "On Dynamo-Electric Machinery." This paper contained an account of investigations carried out in conjunction with his brother, Dr. E. Hopkinson, with the object of obtaining an approximately complete construction of the characteristic curve of a dynamo of given form from the ordinary laws of magnetism and the known properties of iron,' and to compare the results with the actual characteristic of the machine. Another very important

paper, "On the Electrical Illumination of Lighthouses," was read before the Institution of Civil Engineers in 1886. Dr. Hopkinson was elected a Fellow of the Royal Society in 1878, and he is a member of the Senate of the London University. In 1890 the Royal Society awarded to him one of the Royal Medals, and during 1890 he was the president of the Institute of Electrical Engineers. He is member of council of the Mechanical Engineers, and is professor of electrical engineering in King's College, where he does not lecture, but closely superintends the laboratory.

Hopkinson, Edward, M.A., D.Sc., M.I.C.E. Born in 1859, son of Alderman Hopkinson, M.I.C.E., of Manchester. Educated at Owens College, Manchester, and obtained an exhibition in mathematics at Emmanuel College, Cambridge, in 1877, and subsequently a Foundation Scholarship. He graduated as tenth wrangler in the mathematical tripos of 1881, and was elected to a fellowship at Emmanuel College in 1883. In 1881 he took the degree of D.Sc. in the University of London in the branch of electricity and magnetism treated mathematically. In 1882 Dr. Hopkinson became assistant to the late Sir William Siemens, and continued with him until his death. During this time he carried out the experiments at Portrush in connection with the first electrical tramway in the United Kingdom. He received a silver medal from the Society of Arts for a paper on the Portrush tramway, read before the society. After the death of Sir William Siemens, Dr. Hopkinson designed and carried out, in 1885, the Bessbrook and Newry electrical tramway, which is worked entirely by water power, and still continues to be the only electrical tramway on which both goods and passengers are carried on a large scale. He read a paper before the Institute of Civil Engineers on the construction and working of this tramway, which was awarded a gold medal and Telford premium. In 1887 he became a partner in the firm of Messrs. Mather and Platt, of Salford, and undertook the charge of the electrical engineering department, of which he continues head. He is the inventor, in conjunction with Dr. John Hopkinson, of the Manchester dynamo, and of various improvements in connection with dynamo machines and the applications of electricity. He is the joint author, with Dr. John Hopkinson, of a paper on "Dynamo Electric Machinery," printed in the *Transactions* of the Royal Society. He designed the electrical plant for the City and South London Electric Railway, and the electrical part of the work was carried out under his direction.

Hammer, William J., at present a consulting and supervising engineer, is especially well known for his long and intimate connection with the rise of incandescent lighting in America. He was one of Mr. Edison's private assistants in the Menlo Park laboratory at the very beginning of the development of the incandescent lamp. In connection with Mr. E. H. Johnson he established the first station in the world for incandescent lighting as electrical engineer of the English Edison Company, and superintended the elaborate Edison display at the Crystal Palace Electrical Exhibition in 1882. During the next two years he was chief electrician and engineer of the German Edison Company, and introduced incandescent lighting into Berlin. For two years he served as chief inspector of central stations of the Edison Company, and represented that organisation at the Franklin Institute Exhibition in 1884, the Cincinnati Exhibition of 1888, and the Paris Exhibition of 1889. He constructed and operated the largest plant of electrical engineering work ever made for special effects at the Centennial Exposition of the Ohio Valley and Middle Atlantic States in 1888. He has acted in an expert capacity for the various Edison interests in connection with the Ponce de Leon plant and others, and conducted the most elaborate economy test upon the Harrisburg station which has ever been made in that country. Mr. Hammer conducted some remarkable experiments in sound transmission between New York and Philadelphia, employing both telephones and phonographs, which received great attention here and abroad, and on account of which he was presented to the French Academy of Sciences and the International Society of Electricians. He has made some highly interesting and original experiments in war ballooning, signaling, sound, and special applications of electricity, and owns a large number of patents for his own inventions. He was one of the three incorporators of the Sprague Electric Railway and Motor Company, and as manager of the Boston Edison Company established the first commercial station for transmission of power, installing at first 92 motors. He is well known in connection with the development of the phonograph. At present he is working as an engineer on his own account. Soon after the inauguration of the 1892 exhibition at the Crystal Palace, Mr. Hammer came over to England as representative of various American interests—among others, those of Mr. H. Ward Leonard, the Carpenter Heating Company, the Ries Electric Specialty Company, the Weston Electric Instrument Company, Ward Arc Lamp Company, Telemeter Company, Pilkington and White, and others. During his long and intimate career with electrical developments Mr. Hammer has taken a great part in disseminating information, and is always alert to fully investigate any improvement which may be brought to his notice. He is vice president of both the American Institute of Electrical Engineers and the New York Electrical Society, and prominently identified with all the American electrical organisations. His numerous friends, whether on this side or on the other, can fully rely upon his business instincts when trusting their business into his hands. If we permitted ourselves to discuss the merits of Mr. Hammer from a social point of view, we fear his numerous friends would impugn the possibility of getting sufficiently vigorous language to adequately express their high appreciation of his character.

Bennett, Alfred Rosling, M.I.E.E. Born in London March 14th, 1850. Educated principally at Belle Vue Academy, Greenwich. Mr. Bennett is best known to the electrical world at the present time as one of the ablest, if not the ablest, of telephone engineers. For years the study of telephony in all its details has engaged his attention, and in carrying out practical work he has been pre-eminently successful. Mr. Bennett, however, had the great advantage of coming into telephonic work with a mature and ripened experience in telegraphic work, for so long since as 1860 he went to India in the service of the Indian Telegraph Department, where he had a varied and very successful experience. On his return to England in 1873, he for a year or so was with the Highton Batteries Company, and afterwards with the Magneto Company. During the period to May, 1880, he was active in different directions, paying considerable attention to literary work, but in May, 1880, he joined the United Telephone Company, and from then to now has gradually won a foremost position in the industry. He is answerable for many improvements in telephonic apparatus, some of which were patented. In 1883 he joined the National Telephone Company as engineer for their Scotch and Irish districts. We cannot here enter into a critical consideration of papers read or improvements made in apparatus, but in both directions very valuable work has been done by Mr. Bennett. We might just refer, however, to the exceedingly interesting papers read at the Institution during the Edinburgh Exhibition, and more recently at the British Association. Subsequently severing his connection with the National, he became engineer to the Mutual, and strongly advocates the complete metallic circuit system, which under his directions has been admirably carried out at Manchester; and throwing in his lot with the New Telephone Company in London, he has been instrumental in assisting to rouse public action towards improving the telephonic facilities of the metropolis. We can only trust that these labours will lead to London taking the foremost place in telephony that its size and wealth predict.

Garcke, Emile, is the managing director of the Electric and General Investment Company, a very successful company which he and others formed in 1890 to facilitate the promotion and development of undertakings for electric lighting, traction, transmission of power, and other industrial uses of electricity. He became connected with the electrical industry in the beginning of 1883, when he joined the Brush Company. Since then he has been closely identified with the progress of that company, having been successively secretary, manager, and managing director. He has lately resigned the management of the

company, but he still occupies a seat at the board. At the last general meeting of the shareholders, the Duke of Marlborough, the chairman of the company, speaking of the City of London electric lighting undertaking, said: "I cannot impress upon you too strongly what an immense advantage it is to you to have obtained this valuable order, and in passing I cannot help saying that you owe that entirely to the services and persistent labour of your managing director. Although your board have given every attention that they could to your affairs, it would have been impossible for them to have negotiated this enterprise. For several years Mr. Garcke has been working at this thing, and he has succeeded in carrying it out, and I must say that I think it is largely owing to his successful labours in this matter that we were able to come forward and make such a favourable report to you, not simply with regard to the balance sheet, but with regard to the prospects of your company generally." But it is not only on behalf of the Brush Company that Mr. Garcke has done good and hard work. Our contemporary the *City Leader*, in one of its recent articles on "City Men at Home," stated that it is admitted even by Mr. Garcke's rivals in trade that while he has pushed forward the interests of the Brush Company, he has always kept in view the welfare of the industry. He was one of the first to take up the question of the amendment of the Electric Lighting Act of 1882. He organised, with Lord Thurlow, the first deputation to the Board of Trade on the subject, and afterwards acted as hon. secretary to the committee which, at the suggestion of Mr. Chamberlain, was constituted to draw up draft clauses. He is one of the vice-chairmen of the Electrical Section of the London Chamber of Commerce. He is also a director of the Chelsea Electricity Supply Company, of the County of London Electric Light Company, and of the Bath Electric Company. He is a Fellow of the Royal Statistical Society, member of the Institute of Electrical Engineers, of the Institute of Actuaries, and of other societies.

THE TRAMWAYS INSTITUTE OF GREAT BRITAIN AND IRELAND.

Between 70 and 80 members and visitors, among whom was a sprinkling of electrical engineers, assembled on Tuesday at a special general meeting of the Tramways Institute of Great Britain and Ireland, held at the Guildhall Tavern, E.C.

Tramway men had met to discuss their own particular business, and electrical engineers had gathered to once more lay before the former the subject of electricity as a motive power. Mr. W. Carruthers Wain, who presided, was unanimously re-elected president for the forthcoming 12 months, on the motion of Mr. A. P. SMITH, seconded by Mr. G. P. BRADFORD. Other formal business was then transacted, after which

Mr. ELLIOTT, the secretary, presented the annual report, from which it may be interesting to give the following abstract. It was therein pointed out that 34 companies were members of the institute, and that there were also 62 delegates and 150 associates. This showed an increase of five companies since the last report, of six delegates and 52 associates. On the other hand, two companies had ceased to belong to the institute (one owing to liquidation, and the other to legislation), whilst 12 associates had ceased to be such owing to promotion, resignation, and death. The council urged most strongly upon the members of all classes the paramount interest to increase, by the addition of other companies and associates, the power and influence of the institution, as there could be no doubt that one result of the general election would be legislation which, unless carefully supervised and properly dealt with, must have injurious effects upon tramways and the shareholders. The desire of the council had been to bring before the members the latest inventions in traction or improvements on existing methods, and any other inventions having for their object the benefit of tramway companies. In these directions they had been successful. With regard to the matters discussed at the three meetings held during the year, they included, amongst others, the rating of tramways, the traction of tramways by means of compressed air, oil, gas, and electricity, new brakes; and the amendment required to the Tramways Act of 1870. It was to be regretted that the Board of Trade had refused to give facilities for the promotion of the Bill prepared by the institute for the amendment of that Act. The Board had also declined to support, and refused to assist, a motion to be brought forward for an enquiry to be made into the working of the Tramways Act of 1870. They, however, hoped "that in the event of a Unionist Government being returned the matter might be considered favourably next year." The result of the policy of the Board of Trade in this direction was that tramway progress had been greatly retarded.

Mr. CARRUTHERS WAIN, in moving the adoption of the report and accounts, congratulated the members on the satisfactory condition of the institute. He quoted Mr. Preece's figures concerning the development of electric tramways since Siemens constructed the first electric tramway from Berlin to Lichterfeld 11 years ago. What a difference there was between England and the United States as regarded electric lines! Certain tramway companies, as the report had pointed out, had had to go into liquidation, and in the case of Blackpool the Town Council had actually refused to renew the lease to the present company, and was now advertising for tenders all over England. Even with this discouragement, they had endeavoured to make good progress, as, for instance, the line in Leeds, due to the enterprise of America, and at Bradford there was a short trial line due to a firm of electrical engineers. In South Staffordshire they were going to have an installation which he hoped would be opened in time for the next quarterly meeting. With regard to the different inventions the promoters would find, as they (the tramway companies) had found, that it was almost as difficult to secure capital to buy them as it was to purchase tramways. The local authorities should have the tramways and the companies should work the lines; but municipal authorities should, for various reasons, not operate the tramways. After giving some figures concerning the slow growth of tramways in the United Kingdom, he concluded by impressing upon the members that pressure should be brought to bear upon parliamentary candidates at the forthcoming election, so that a committee should be appointed to enquire into the working of the Tramways Act of 1870.

Mr. A. P. SMITH seconded the motion, which was carried.

The report of the committee on mutual assurance against accidents was then presented by this gentleman. The report recommended generally that a company should be formed to undertake the insurance of the tramway plant. In the discussion on this matter a difference of opinion was expressed as to whether, among other points, if such a company were formed, it could be made self-supporting, and as to the liability of one company running steam cars and another operating with horse cars. It was eventually proposed and carried that the meeting generally approved of the outlines of the plan, that the committee was authorised to take such further steps as might be desirable, and that the matter be reported upon at the next meeting.

Mr. F. ARNALL, A.M.I.C.E., assistant surveyor of Birmingham, then read the following paper on

PERMANENT WAY CONSTRUCTION, ESPECIALLY AS REGARDS WEAR AND TEAR AND DEPRECIATION.

When tramways were first laid in Birmingham, the question arose as to whether they should be laid and maintained by the Corporation, or whether this work should be left to the company working the line. It was thought that as it was the duty of the Corporation to maintain the roads, it would not be altogether right to delegate that duty to a company whose used a part of the road for their private business, and whose primary object was not the care of the road, but the making of a profit in the using of a part of it. It was recognised, even in that early day of tramway enterprise, that from various causes the object for which the company had been called into existence might become a very difficult one to attain, and as the interests of the company and of the public using the road were not

identical, it was likely that there would be a tendency for the company to neglect the maintenance of the roadway. It was therefore decided that the tramways should be laid by the Corporation, and maintained by them on terms to be agreed upon with the several companies concerned.

The first tramways were laid in Birmingham in 1872, and in 1875, the lines forming a continuous route, about 4½ miles long, from one side of the town to the other. It was nearly all double line, and laid to a 4ft. 8½in. gauge. In construction the Larsen system was adopted—an iron rail laid on a continuous wooden sleeper, as shown in section in Fig. 1. It was found that although the rail was fastened to a continuous wooden sleeper its bearing upon it was evidently very discontinuous: the wood warped and shrunk in a way that the iron rail could not follow, and however firmly it was fastened down it soon worked loose. As this system of construction in and about Birmingham is, however, now a thing of the past, it is hardly worth while now to go into detail as to the merits or defects it possessed. A part of it was taken up in 1887 for the construction of the Hockley cable tramway, and the remainder in 1889 for the construction of the Bournbrook electric line.

Steam traction was introduced into Birmingham in 1882, and it has since received a very extensive development; its growth was rapid, but soon checked. Between 1882 and 1887 the three companies using steam on the Birmingham tramways acquired altogether about 120 locomotives,

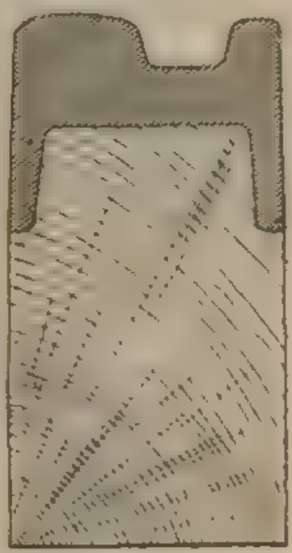

Fig. 1.

and I believe the various companies have always done their best to keep as many as they possibly could at work on the roads. This paper deals more particularly with the effect of this steam traffic upon the tramways, rather than with the tramways themselves, and the Birmingham results are the more important because the traffic upon the lines is so exceptionally heavy. In some streets there are four lines of routes overlapping each other, and in other streets as many as five lines, each route having quite a full complement of cars running over it. The result is that we have as much wear and tear on these tramways in five years, or in four years, as the case may be, as we get on a single route in 20 years. This is, of course, apart from the effects of ordinary traffic, which I believe to be very small indeed.

Knowing, then, the actual amount of wear in five years where four routes run over the lines, we have a good guide as to the amount of wear to expect on a line over which the traffic from only one route passes will sustain in 20 years. Many things may conspire to increase the effect on the single route in the long period of 20 years, such as corrosion, the long-continued effect of ordinary traffic, the natural growth of the district and consequently more frequent service, and so on, but I know of nothing that can possibly diminish the effect, except that the engines, etc., taken over the lines be reduced in weight or number, which can hardly be expected.

This point of view does not seem to me to have yet received at the hands of the institute the attention which it deserves, especially bearing in mind its important bearing upon the question of depreciation, or of prolonged maintenance, as apart from casual everyday repairs. Generally speaking, every case of repairs is a renewal of some part or another; it may be the replacing of a broken point, or only the renewal of the bedding under the adjacent paving stones, or of the grouting between them. Those engaged in the maintenance of steam tramways generally have a pretty good notion as to what everyday repairs means, but the almost imperceptible wear and tear to the rails themselves, which is always going on but which generally takes a long time to make itself visible, when not overlooked altogether, is generally only provided for in an indefinite sort of way by a depreciation fund. The traffic on some of the steam routes in Birmingham has already produced some results which may serve as data to assist in determining what this depreciation fund should be in similar circumstances, and, properly interpreted, may even be of service in circumstances which are not similar.

The first tramway laid for steam in Birmingham was the Birmingham and Aston route in 1882—a length of about one mile of double line inside the borough, laid by the Corporation, and a further length of about three miles or thereabouts in the district of the Aston Local Board, laid by the Aston Tramway Company. The gauge was 3ft. 6in., the rail used being that known as Barker's: a steel rail, 42lb. per yard, keyed to a cast-iron sleeper, as shown in section in Fig. 2. The sleepers were cast in lengths of 2ft. 11in. each, and laid with a gap of only 1in. between

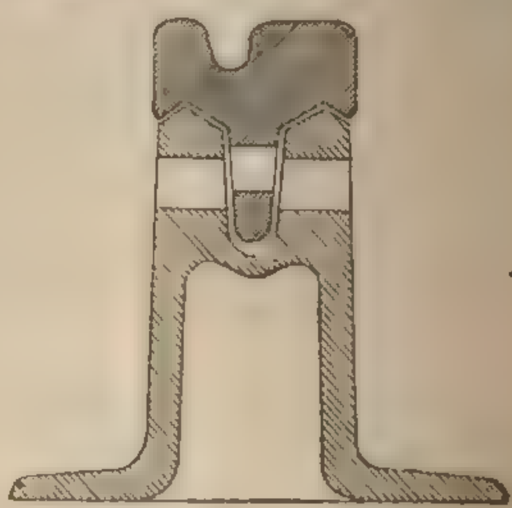

Fig. 2.

them, so that they were practically continuous. They were moulded by machinery, and were as nearly true on the upper surfaces as castings not machined over can be, and though they formed a nearly continuous line, it soon became evident that they did not form a continuous bearing for the rail. In a very short time after the line was opened, the rails began to work loose at the joints, which were always in centre of sleepers, and in spite of all tightening up and replacement of keys, this defect gradually spread along until the rail was loose from one end to the other; and the next result was, of course, the loosening and sinking of the paving stones along side. A length of 200 or 300 yards in Corporation street was left unpaved, and here the keys could be readily got at for tightening up, etc., but it was found that the rail did not become loose because the keys were not tightly driven in, but because they were cut away by the harder rail. A trial of some steel keys was made, but it was found that they caused the edge of the hole in the rail itself to cut away, so they had to be abandoned.

It was found that the steam traffic was really subjecting the rail to a process of "cold rolling," which lengthened out the upper surface, while the lower parts of the rail remained unaltered. As a result the rail tended to assume an arch or bow form, and when all the keys in a 30 length of rail had been knocked out, the loose rail rose in the centre 6in. or 9in. It, furthermore, was no longer straight on plan, but curved, the tread or bearing surface of the rail being on the outside of the curve. The effect was that when keyed

down the rail was always in a state of strain, and the least looseness in the keys caused it to rise above its bed, and at the same time the horizontal curvature caused it to move sideways, so that when a car passed over it the lower parts of the rail did not fall directly in their proper places on top of the sleeper, and dust and grit from the road surface formed a most efficient grinding material which was constantly being renewed. Thus, the top of the sleeper wore away as fast, practically, as the top of the rail, and it, moreover, wore out of shape, and the notion that we should be able to replace the rails when worn out without having to disturb the sleepers, had to be definitely abandoned. This process went on until the flange of the wheel reached and run on the bottom of the groove, and then destruction went on more rapidly still, until towards the end of 1886, when the lines had been in use four years, some of the rails began to split along the groove and had to be taken out, thus terminating their career.

Four years seems a short life for a tram rail, but the conditions must be taken into consideration. The rail was in a macadam road, and the traffic over it, amounting to perhaps 30,000 steam cars in 1883, had rapidly increased until the fourth year, when it had to carry the traffic from five different routes, amounting to 120,000 cars in that year. The total in four years amounted to about 280,000 cars, roughly equivalent to somewhere about an average of a five-minute service during the period.

In lower parts of the tramway, where the road was paved all across, and where some of the traffic had been diverted

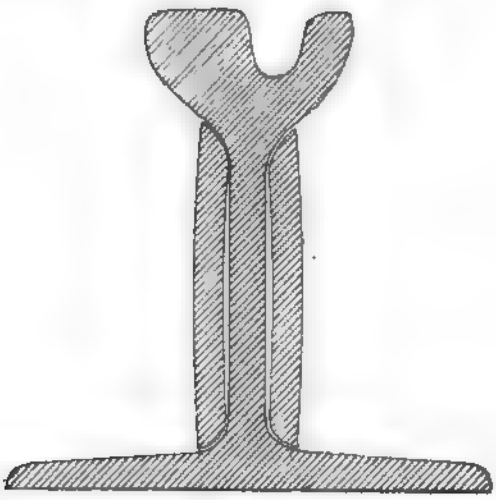

FIG. 3.

down other streets, the wear and tear was not so great—nevertheless, it was found necessary to take out and replace all the rails before the end of 1889, after the passage over them of about 380,000 steam cars in seven years. Outside the borough boundary the tramway company contrived to carry on for a few months longer, but took out their rails in the following year, after having been in service about $7\frac{1}{2}$ years and carrying the traffic of rather more than 400,000 cars.

Our experience thus shows that, apart from all questions of ordinary everyday repairs to paving, points, etc., the Barker rail will be worn out and done with, and must be replaced, after the passage over it of about 400,000 steam cars. If the new rails have to be put in in the nighttime and without disturbing the traffic, it may be taken that a mile of single line will cost about £2,000 in relaying it with girder rails, which is equivalent to about $1\frac{1}{4}$d. per car mile as a sinking fund to provide for the replacing of the rails alone.

The results I have indicated were, of course, not arrived at until after the Barker rails had been laid down for several years, but before even they were opened for traffic opportunity had been taken to examine the system and to gain lessons from its use elsewhere. The result was that when, in 1883, the Corporation were called upon to construct tramways for what is now called the Birmingham Central Tramways Company, the conclusion had been arrived at that the system was not suitable for steam traction. Considering the extensive system of tramways that the Central Company proceeded to construct, or have constructed, and the nature of the agreements already entered into between them and the Corporation, it is not too much to say that this decision of the Corporation has proved to be one of the utmost importance to the company.

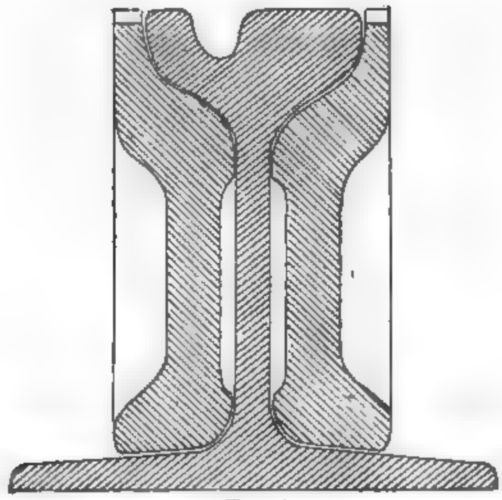

FIG. 4.

The system decided upon for the new tramways was the Gowan, or girder, rail, 7in. deep, to suit 6in. paving, 7in. wide on bottom, and weighing 98lb. per yard, the section being as shown in Fig. 3. The tenders of the Barrow Hæmatite Company were accepted for the supply of rails and fishplates, and, in fact, all the rails of this section hitherto laid by the Corporation have been supplied by the Barrow Company.

The joints were made of two 16in. fishplates, with four bolts, and were generally found to stand very well on a single route of tramway for the first two or three years, equivalent to the passage of, perhaps, 60,000 to 70,000 cars over them. After this they began to work loose, and the remedies resorted to—viz., tightening up the bolts and often replacing them, repacking the rail, etc.—are found to be only a temporary cure. For some time it was thought that the working loose was due to the nuts slacking back, or to the bolts stretching, and various varieties of locking nuts were tried, but with no beneficial results. The bolts may certainly have stretched a little, but the nuts certainly did not slack back or work loose, and it appears that the failure at the joints was due to several causes, which may produce different results under different circumstances.

It is not easy to imagine how a line of rails, properly fished together, and supported continuously on a solid bed of concrete, can work loose at the joints, but it is very certain that they do. The chief reason is to be found in

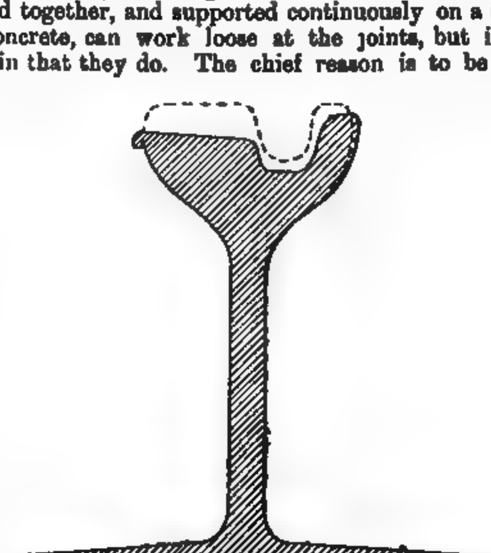

FIG. 5.

what I believe to be the fact, that on a steam route the rail generally is not continuously and equally supported, and, furthermore, it never can be for long together. The rail bears more solidly in some places than it does in others, bridging over the hollow places, and there is consequently

a minute deflection as the load passes over the places that are least firmly supported. When the joint happens to be over one of these slack places in the concrete the deflection will be greater. In the section of rail under discussion, deflection can readily take place, the head of the rail sinking between the tops of the fishplates, wedging them open. To be effective in resisting a tendency of this sort, each fishplate should act like an arch, the bolts passing through the

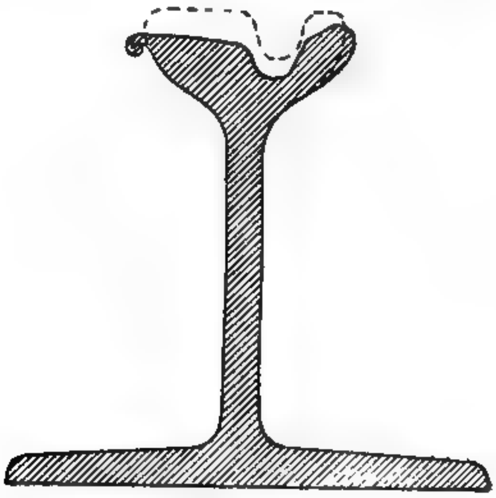

Fig. 6.

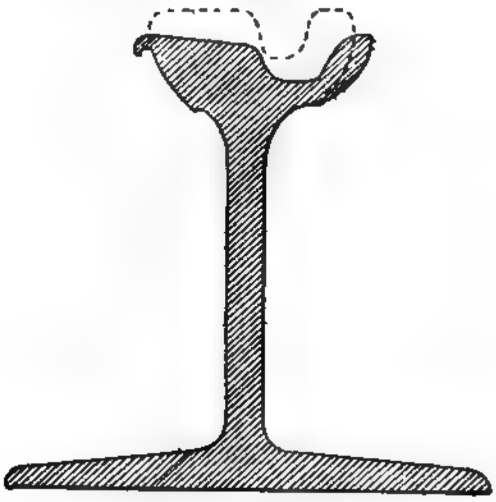

Fig. 7.

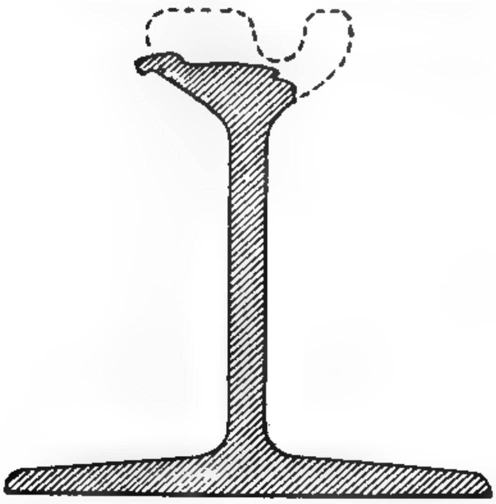

Fig. 8.

crown, the abutments being at top and bottom of the plate. In the Birmingham section, however, though we have a fairly good abutment at the bottom, there is a very bad one at the top, and sliding can very readily take place there, and does. The narrow edge of the plate is not a good surface for withstanding an action of this sort: it is too narrow; this is very plainly seen when a loose plate is an off, the top and bottom edges being often ground quite bright and smooth, and, generally, a more or less ledge is worn in them by the extreme ends of the rails

Many attempts have been made to deal with this w ness at the joints, with but imperfect success. In the route constructed by the Corporation the length of plates has been increased from 16in. to 24in., and number of bolts from four to six, but the traffic on this is comparatively slight, and as yet the soundness of

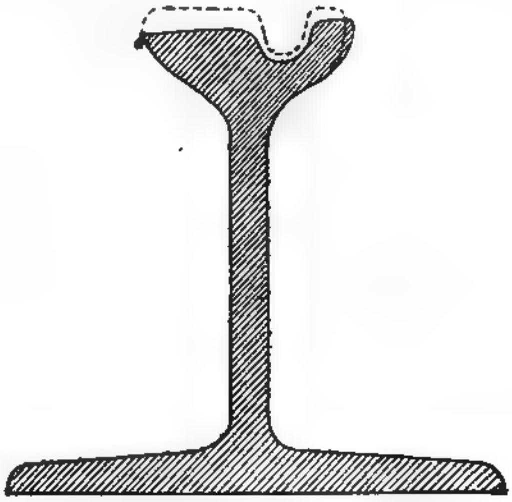

Fig. 9.

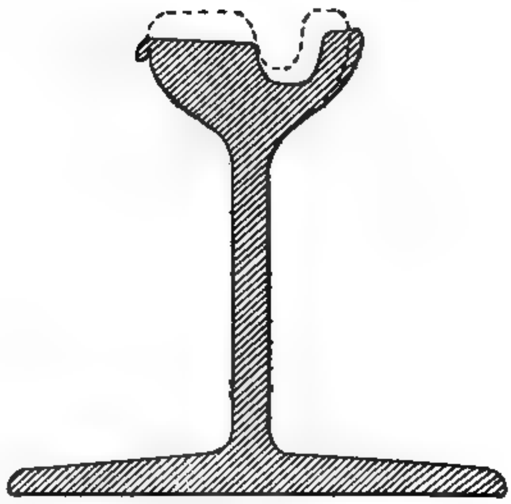

Fig. 10.

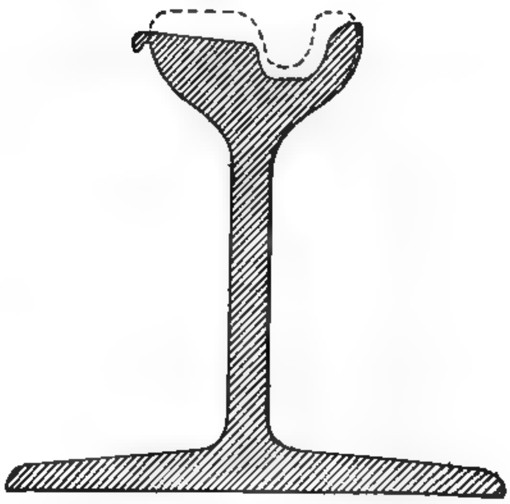

Fig. 11.

joints upon it is no criterion of what we might expect steam route with heavy traffic. A large number of Man sole-plates have been used; at first the plates were long, with four clips on each side, but these not bei all respects satisfactory, the length was increased to These long plates were practically no better than the ones, if so good. More close attention being paid movements of a loose joint under the traffic, it was

that the defect was rather with the clips, so I suggested that the two centre clips should be brought close together, and coalesced into one, the two bolts being retained. This form of clip turned out to be a great improvement on the old form, and I believe the plate is now as good as a sole-plate can be expected to be. It should be remarked that in our work these plates have been under one disadvantage, inasmuch as with the exception of one route, and that of light traffic, they have been put under joints that were already faulty, and mending a bad joint is not such easy work as delaying the failure of a good one.

To find what the effect of increasing the bearing area at top and bottom of the fishplates would be, a number of C.I. plates, 16in. long, and of the section shown in Fig. 4, were prepared. They fit the rail closely top and bottom, and the top is brought up to the street surface, and finished with a corrugated surface, and it will be seen that in screwing up the bolts there can be no tendency to make them ride up on their abutting surfaces. A trial length of line was selected, and a number of these plates put in in the autumn of 1890 in a street of very heavy traffic, and their behaviour is being compared with joints of other forms made at the same time in the same street, and under precisely the same conditions. They are still standing very well; where these plates are used without sole plates the joint seems about equally good as where ordinary fish-plates and sole plates are used, and where it has been used combined with a sole plate, the joint is better than any that has yet been tried in Birmingham. As the plates have been in a year and eight months only, it seems too soon to speak very positively of their merits; nevertheless, it is worth remarking that in that time they have had more than 250,000 steam cars over them, or the equivalent of a 10 minutes' service for about 12 years.

To refer again to the "cold rolling" process which has been already mentioned, I am persuaded that this action is one reason why we have so much trouble with the joints; its whole tendency is to lift the rail off its bed, allow dirt, etc., to get underneath in irregular patches, and thereby destroy the continuity of the bearing. The dipping at the joints, which is such a marked feature in a well worn steam tramway, is not so much a lowering at the joints as a lifting of the intermediate parts of the rail; and it is found that whenever a rail gets this hog-backed appearance, the trouble with the paving, which at first was only experienced at the joints, is now found pretty general all along the rail. It is furthermore to be remarked that the curving up in the centre is very much more with the same amount of traffic on a 6in. rail than it is on a 7in rail, and so much is this so that I venture to advance the opinion that nothing less than a 7in. rail is fit for use on a steam tramway of even moderately heavy traffic.

I have here, Figs. 5 to 11, actual sections of some rails that have been taken out of the Birmingham tramways, showing the effects of wear upon them.

No. 5:	Straight line, effect of	550,000	cars.
No. 6:	Flat curve	570,000	,,
No. 7:	Sharpe curve	570,000	,,
No. 8:	Straight line	560,000	,,

This example shows effect of expansion in wood paving, when allowed to become excessive.

Nos. 9, 10, 11: Straight line, effect of 670,000 cars.

All these sections show more or less the effect of tilting over of the rail, which is always to be found on a steam tramway, has upon the wear and tear of the rails the tread is not worn evenly down, but more rapidly towards the groove, leaving the flange standing up as a more dangerous obstacle to the ordinary traffic. From them some idea may be obtained of the great advantage which a rail with a central groove would have over one of the ordinary section.

These sections show that on a straight road a girder rail will be worn out, and require replacing after the passage over it of less than three-quarters of a million of steam cars. Many things may cause the number to be less, but nothing, except reduction in the weight, can cause the number to be greater. Taking the cost of relaying at £2,000 a mile, it works out that over and above the cost of everyday repairs, and maintenance of paving, etc., a damage to the extent of certainly over ·5 of a penny per mile is accumulating on the rails, and may some day want paying off all at once. How this liability is to be provided for is for the company to determine, but it seems to form a very definite factor in any depreciation fund that may require to be set aside to provide for future requirements.

Mr. COX, in the discussion, said the difficulty was at the joints. He had tried Marshall's sole plates, and was now trying Whytehead's joint-chair and fishplate. In the course of his experience he had found that single lines on tramways worked by steam wore as long as the double lines. Steam engines and cars passing all in one direction tended to break down the joints very much indeed; but on a single line that was counterbalanced by the traffic going in each direction. On the lines he was connected with, the fishplates wore in the same manner as Mr. Arnall had explained. They were 16in. long and ½in. thick at first, but better results had been obtained with longer plates ¾in. in thickness.

Mr. WROUGHTON was of opinion that the Barker rail gave "more trouble than enough." In 1886 his company had laid a short length of line with transverse sleepers where the road surface was very hard, and when General Hutchinson made an inspection recently, he was surprised to learn that not a single joint had been touched or anything spent on the paving. Cross sleepers were no doubt the best system.

Mr. A. DICKENSON, of Darlington, congratulated the author of the paper, and suggested that one of the methods by which the difficulty of joints might be overcome would be by reducing the number of the joints, and for that purpose electric welding or some other process could be used.

Mr. J. WAUGH, of Bradford, believed in the use of the Barker rails, which he had found to stand exceedingly well.

Mr. BRADFORD was strongly of opinion that transverse sleepers were the best. There was less oscillation when the foundation was firmer, and it was the oscillation which caused the joints to break; he was thoroughly convinced that cross sleepers were the best, and they ought to be used.

In the course of his reply, Mr. ARNALL stated that he did not think that the Whytehead joint-chair and fishplate would remedy the evil of the joints. People had made a diligent search for something to cure the evil of the joint, but up to the present they had not found it. The trouble did not so much arise from the inherent weakness of the joints, but from that process of "cold rolling" on the top of the rail. He agreed with what Mr. Cox had said regarding the cost or wear of the single and double lines. He had tried to discover the difference between the two, but could not do so. With reference to electric welding, he did not agree with Mr. Dickenson on that point, as such a process would increase the trouble through "cold rolling," to which he attached great importance. The cross sleepers would diminish noise, but, in reply to a question put by the president, he was unable to state what was the best system of laying tramways.

Mr. SHARP next read a paper on "The Further Development of the Connelly Motor in England and America."

The following paper was presented by Mr. G. ANNESLEY GRINDLE, C.E., on

ELECTRIC TRACTION: THE CITY AND SOUTH LONDON ELECTRIC RAILWAY.

The use of electrical energy to actuate motors for producing mechanical motion followed closely on the introduction of electromagnets. The first who seriously applied it to traction purposes appears to have been a Scotchman named Davidson, who during the years 1837 to 1839 constructed and worked a so-called locomotive capable of carrying two persons. The source of power was a primary battery, and, as may be imagined, the motor, or rather motors, were of a very crude description. But the idea was more than a mere toy, as the car measured 16ft. by 6ft., and the total weight some five tons, while a speed of four miles an hour is said to have been attained. From this time on there were many and varied attempts to solve the problem, but the want of a reliable and reasonable source whence to obtain the necessary current militated greatly against any good results, and we may therefore

pass over the period that elapsed, noting the invention of the Pacinotti machine in 1861, and the subsequent Gramme machine 10 years later, till the Vienna Exhibition of 1873, when the first practical and serious demonstration of electricity as a motive power was exhibited a Gramme dynamo, driven by a steam engine, transmitting the current to a similar Gramme machine at a distance of nearly half a mile, and from which power was taken to work a pump. Subsequent to this the application of electricity as a producer of motive power progressed but slowly till the summer of 1879, when a small experimental railway was laid down at an exhibition in Germany. The successful result of this small line already foreshadowed what could be done in this direction, and in 1881 an electrical line was permanently laid down for passenger traffic in Berlin, and continues in operation at the present date. In both the latter instances the electric current was gathered from the conductor as the car advanced, but at the close of 1881 the rapid development of storage batteries or accumulators gave fresh impetus to traction work, especially self-contained cars, and many and varied experiments and demonstrations have followed which are of sufficiently recent date to call for no special reference. The bulk, however, of these schemes and experiments has dealt only with light work, such as running of tramcars, and very little until quite recently has been done in what may be termed heavy work—that is to say, running of heavy trains and at considerable speeds. The first step in this direction was the Portrush, Bushmills, and Giant's Causeway tramway in the North of Ireland, which was opened in 1883.

This line when originally opened was some 6½ miles in length, and has since been extended an additional two miles. The line runs along the roadside with many very severe curves and gradients, and has a 3ft. gauge. The current is generated by water power, and conveyed to the motor by a rail erected at a slight elevation along one side of the track. The equipment consists of motor-cars, but the loads carried are not of very great weight. Steam power traction is also employed in the working of the line, which makes it somewhat difficult to arrive at the actual result and cost of the electrical working.

Following in this came the Bessbrook and Newry tramway, which may be regarded as the first serious attempt to deal with heavy goods, mineral, and passenger traffic. This line was opened for traffic in October, 1885, and, in addition to passenger traffic, has to deal with a heavy goods traffic. The line is a little over three miles in length, running from the Great Northern terminus at Newry to Bessbrook, and is built on private property. The gauge is 3ft., while the gradients average 1 in 80, with a maximum of 1 in 50. The line has practically a steady rise in one direction against which the motor has to draw a load of 18 tons, plus weight of car and passengers, at a speed of six miles an hour, or a load of 12 tons at nine miles an hour. The power for working the generating dynamo is obtained from turbines at a spot about midway along the line, and the current is conveyed to the motors through a steel conductor laid midway between the main rails. Two motor-cars, carried on 4ft. six-wheel based bogies, form the locomotive equipment, each car carrying 34 passengers, and weighing 8½ tons without passengers and equipped with an Edison-Hopkinson dynamo-motor of a normal output of 20 h.p., but which power in practice is often exceeded. The electric generating plant consists of two Edison-Hopkinson dynamos, capable of developing about 25 h.p. each. Only one is used at a time, and is found to be amply sufficient for the work required. The designing of the plant and equipment of the line was carried out by Messrs. Mather and Platt, of Manchester, to the plans and under the superintendence of Dr. Edward Hopkinson.

The conditions under which this line was constructed were fairly onerous. An outline of them was published in the *Proceedings* of the Institution of Civil Engineers, from which I make the following extract: "The company agreed to place the line entirely at the disposal of the author for a period of time, and to purchase the electrical plant at a fixed sum when the above conditions had been complied with, and it had been shown that the cost of working, as evidenced by six months' trial, did not exceed the cost of steam traction on a similar line. The work was commenced in November, 1884, and the line opened for traffic in October, 1885, and was formally taken over by the company, as having fulfilled the conditions of the contract, in the following April." Since that time it has been in regular daily operation. Considerable credit is due to the constructors for the way in which the matter was faced, the risks incurred, and the initiative made in this heavy class of work.

Following on this comes the subject of the present paper, and a short history here may not be out of place. In 1884 an application was made to Parliament for powers to construct an underground line from the City to the Elephant and Castle and granted. The want of such an undertaking had long been felt, and various schemes had been suggested to afford facilities for communication between the City of London and the densely populated districts on the south side of the river, and relieve the congested traffic over London Bridge, which, in 1886, when the railway was commenced, was estimated at 7,000,000 vehicles and 56,000,000 foot passengers per annum. The course taken for the line was from a terminal station adjoining the Monument, under the Thames, a few yards above London Bridge, and beneath the Borough, Blackman-street, and Newington causeway to the Elephant and Castle, following, as nearly as possible, the line of roadway, and so avoiding the cost of land purchase and compensation. The work of construction was commenced in 1886, and so gratifying were the results of the operations on this first section, involving as it did the difficulties of tunnelling under the Thames, that the directors applied to Parliament in 1887 for further powers authorising them to extend the line to Stockwell—making in all a distance of some 3¼ miles. The route for this extension was from the Elephant and Castle along the Kennington and Clapham roads, with stations at Kennington, Kennington-oval, and Stockwell. The work of the extension proceeded concurrently with the completion of the original section, and for obvious reasons the opening of the first portion was delayed until the completion of the scheme in its entirety from the City to Stockwell. Since the opening of the line to Stockwell, further powers have been sought and obtained for an extension to Clapham Common. This extension, however, has not yet been carried out, but will doubtless shortly be commenced, and cannot but prove a valuable addition to the undertaking, Stockwell being at present, at any rate, a poor centre for a terminal station. The system of tunnelling is somewhat novel, and introduced into this country by Mr. J. H. Greathead, M.I.C.E., to whom the design of the line is due, and under whose able superintendence the construction works were so successfully carried out. Entirely separate tunnels are employed for the up and down lines, so avoiding all possibility of collision between trains approaching each other in opposite directions. The material used in the construction of the tunnels is cast iron, built up in consecutive rings, each ring being composed of several segments, with a key piece. The tunnels are driven by a shield, which in form may be described as like a tube some 10ft. or 12ft. long, with a bulkhead, the internal diameter of the tube being slightly larger than the external diameter of the iron tunnel. A short length of soil is excavated in front of the shield, which is then driven ahead by means of hydraulic power, and the segmental ring is built up within the shield tube in the resultant gap caused by the forward movement between the bulkhead and the last built ring of the tunnel. The diameter of each tunnel is about 10ft. The stations are of brick and usual construction of arch and invert, and have a diameter of 22ft. The tunnels run, as a rule, side by side, excepting under the Thames, where one line is directly above the other. The depth of the tunnels below the surface of the roadway varies from 50ft. to 70ft., and is consequently below all sewers, gas-pipes, water-pipes, and subways, and causing no disturbance to the surface of the roadway. At such a depth the question of ventilation would appear to be a serious one, but as a matter of fact the tunnels are self-ventilating, and no special arrangement or machinery whatever is employed to effect what is generally acknowledged to be a very satisfactory

state of the air in the tunnel. This is due chiefly to the employment of separate tunnels for up and down traffic; the trains fit the tunnels almost like pistons, with the result that every train is continually changing the air, pushing, so to speak, a column of air to the station ahead, whence it escapes by means of the lift shafts, and sucking air from the shafts of the station last passed. Of course, at such a depth steam locomotion would be out of the question, and originally it was proposed to work the line by means of cable haulage, and, in fact, contracts for such means of running were actually entered into. In the interval, however, that elapsed between the first conception of the undertaking and the time when its accomplishment was in the near future the application of electricity to traction purposes had been advancing by leaps and bounds, and with the success attained on the Newry and Bessbrook line (on which the loads dealt with, as mentioned before, were but little, if any, less than those it was proposed to run on to South London line), Messrs. Mather and Platt were induced to approach the directors of the line with a view to obtaining their consideration as to the advisability of employing electricity as their motive power in lieu of cable, and to submit a complete scheme for the purpose, together with proposals for the working. The matter was the subject of long and careful deliberation by the board of the company, and was warmly taken up by the chairman, Mr. Charles Grey Mott, to whose untiring energy and deep interest in the matter a great part of the success of the undertaking is due. The submitted scheme was eventually accepted in its entirety, and a contract entered into in the early part of 1889 for the equipment of the line in accordance with the same. In addition to the actual equipment of the line, an offer was also made to work the line for a period of 12 months, or at the option of the company to guarantee the cost of haulage according to a sliding scale, dependent upon the train mileage run per annum, commencing at 3·5 pence per train mile for the full possible mileage of 384,800 miles per half year. The trains under the guarantee to consist of . locomotive, 10 tons; three coaches of 4·25 tons each, and 100 passengers. During the summer of 1889 various experiments were carried out on a short length of the line then completed, by a temporary plant at Great Dover-street Station and two experimental locomotives. The experience gained in these trials was at the same time both unique and valuable, affording an amount of information which had never before been attained, and which proved invaluable in working out many subsequent details. In the meantime the construction of the plant proceeded rapidly. In close proximity to the Stockwell terminus of the line, on a large plot of land which serves as a general depot, a spacious engine-house, in which the entire current employed in working the line is generated, was erected.

The plant supplied consisted of three generating dynamos of the Edison-Hopkinson type, each having an output of 450 amperes at 500 volts. The machines are compound wound, with bar armatures, and are about the largest machines of the class that have ever been constructed, the total weight of each machine being over 17 tons. The driving is effected by means of link leather belts 28in. wide, and to increase the grip, the belt is led under a jockey pulley. Each dynamo is independently driven by a vertical compound engine, designed and constructed for Messrs. Mather and Platt by Messrs. John Fowler and Co., of Leeds. The high and low pressure cylinders are 17in. and 27in. internal diameter respectively, and are both steam jacketed. The stroke is 2ft. 3in., normal running speed 100 revolutions per minute, giving a piston speed of 450ft. per minute. The engines are fitted with automatic expansion gear on both high and low pressure cylinders, controlled by a high speed governor driven by ropes directly from pulley on crankshaft. The steam pressure employed is 140lb. per square inch. The flywheels are very massive—14ft. in diameter, 28in. wide on face, and weigh 14 tons. Each engine will indicate 375 h.p., and in practice two engines and dynamos are employed, and are sufficient to work the entire line, the third engine being kept in reserve. The engines are supplied with steam from six steel boilers of the Lancashire type, 28ft. long, 7ft. diameter, and are fed with fuel by means of Vicars's mechanical stoker. The water supply is effected by means of two Worthington pumps, and before entering boiler is forced through two feed-water heaters, heated by the exhaust steam from engines.

Since the opening of the line, and in view of the extension to Clapham Common, a fourth engine and dynamo similar to the original three have been erected, also two additional boilers. The boiler-house is below the general ground level, which greatly facilitates the stoking, the fuel being simply tipped straight into the hoppers, and so avoiding all cost for elevating, etc. Adjoining the engine house is a fitting shop where minor repairs can be carried out. From the dynamos the current generated is conveyed by means of lead-covered cables to a massive but simple switchboard, and is there distributed to the feeding mains. These mains or cables, of which there are four, are of the well known Fowler-Waring manufacture, and consist of a $^{61}/_{14}$ B.W.G. copper core, insulated with patent insulating material and lead-sheathed. The cables are carried on brackets along the sides of the tunnel, and led into the various signal boxes. In the signal-boxes are fixed small slate distributing boards, fitted with plugs and fuses, and from these the current is conveyed to the working conductor by means of feeder cables. The working conductor is of steel, of channel section, specially rolled for the purpose, and of such composition as to ensure its having a low specific resistance. It is carried by glass insulators, which are cleated with creosoted blocks to the sleepers, and laid between the two main rails at a distance of about 1ft. from one rail—this position being rendered necessary on account of the low position of the central buffer coupling. The lengths of conductor are fished with two small fish-plates and four bolts, as a mechanical coupling, while the electrical connection is ensured by means of a laminated copper strip secured by four copper rivets. The steel conductor is not continuous, but broken at every station. The intervening gap, a length of some 2ft., being made up with a piece of well-seasoned oak, by which means it is possible to isolate any one section of the line without interfering with the remaining sections, or, in case of any accidental failure occurring on any section, it automatically disconnects itself from the system. At the points and crossings, which are in every respect similar to ordinary railway practice, the shoes or collectors have to be lifted over the crossing rail, the level of the conductor being 1in. below that of the main rails. This is accomplished in a simple and effective method by means of inclined wooden planes, up which the shoes run. The insulation throughout the line is exceptionally high. The daily test of the entire system—which includes generators, switchboards, cables, feeders, working conductor, points and crossings, locomotives and lighting circuits with the full pressure of 500 volts—does not give a leakage current of one ampere, or considerably less than 1 h.p., and is often as low as a quarter of an ampere. The conditions of the line naturally are highly favourable in this matter, no difficulty with weather having to be contended with. The return circuit is made by means of the main rails, which are connected, in addition, to the ordinary fish-plates with copper connecting strips fixed in the same manner as in the working conductor.

The electric locomotives, of which 14 were supplied for working the line, were each designed to be capable of exerting a tractive force of 3,000lb., and running at a speed of 25 miles per hour. In general appearance the locomotives closely resemble steam tram motors. The weight of each locomotive is 10 tons, and it is carried on two axles with a wheel base of 6ft. In the construction of these motors a striking and novel departure from anything that had previously been attempted was made with regard to the armature. Instead of being, as in previous engines, connected with the driving axles by means of gearing, belts, or chains, the armatures were actually built up on the axles themselves, thus entirely obviating all the necessary incumbent complications that had hitherto been in vogue. The magnets are supported partly by the axles and partly suspended from the car itself, an arrangement which allows of a certain amount of freedom of angular motion round the axle, yet always remaining concentric with the armature. A separate and independent motor is fitted on each axle. The motors are series-wound,

and the armature revolution per minute, of course, varies with the speed of the train; at 20 miles per hour the revolutions are approximately 250 per minute. The current is taken from the working conductor by means of three sliding shoes fixed by hinged supports to the frame. The shoes are of cast iron, and it is found in practice that they will run about 10,000 miles before requiring renewal. From the shoes the current is carried by an insulated cable to the main resistance switch which controls both motors. The resistances are placed in series with the motors, and gradually cut out as the switch is put over. A second switch controls the reversing movement, which is effected by changing the direction in which the current passes through the armature. The locomotives are fitted with hand and air brakes, the latter being of the well known Westinghouse type, and continuous throughout the train. To work the air brake a supply of compressed air is carried in two steel reservoirs on the locomotive, and replenished at Stockwell on every round journey. Connection between the locomotive and carriages is effected by means of a central buffer coupling. The trains are made up of two coaches, each constructed to carry 34 passengers, open from end to end, with two longitudinal seats like those in an ordinary tramcar. Entrance into the cars is gained by means of end doors, and between the carriages intermediate platforms are fixed, fitted with collapsible side gates. The carriages, which are 29ft. over all, are carried on two four wheel trucks, and, exclusive of passengers, weigh over seven tons each. The lighting is effected by means of incandescent lamps, supplied with current from the working conductor.

The gauge of the line is standard 4ft. 8½in., and the rails, 60lb. weight per yard, are of Ebbw Vale steel. The track is not ballasted, the cross sleepers merely resting on the sides of the iron tunnel. The road has many severe curves and gradients, the sharpest curve having a radius of 1½ chains, and the heaviest gradients 1 in 14 with, and 1 in 25 against, the load.

A complete telegraphic and block signalling system is carried throughout the line.

Such is a brief description of the line and its equipment, the entire electrical portion of the latter being constructed by Messrs. Mather and Platt, of Manchester, from the designs, and under the superintendence, of Dr. Edward Hopkinson, a partner in the firm.

A few words on the working and results may, perhaps, be of interest. On November 4, 1890, the line was formally inaugurated by His Royal Highness the Prince of Wales, who, accompanied by His Royal Highness the late Duke of Clarence, made the journey from the City to Stockwell and visited and inspected the plant and works. Shortly after this the line was passed by the inspectors of the Board of Trade, and eventually opened for public traffic on December 18, 1890.

Upwards of 18 months have therefore elapsed since the public opening, during which time the line has been in daily operation. For the first few months a train service of some 12 trains per hour each way was maintained, but with the growing traffic this has been increased, until at the present time, during the busy hours of the morning and evening, as many as 16 and 17 trains per hour are run. The public appreciation of the line is shown by the increasing numbers of passengers carried. For the half year ending June 30, 1891, the number of train miles run was 141,108, and passengers carried 2,412,343. For the second half-year, ending December 31, 1891, the train mileage run was 188,666 miles, and passengers carried 2,749,055, exclusive of season ticket holders, the revenue from which on the average fare would represent 37,300 additional passengers, or a total of 2,786,355. The revenue receipts and expenditure have been—for the first half year, receipts £19,637, expenditure £15,520, or a balance to the good of £4,117; for the second half year, receipts £20,243, expenditure £15,516, balance to the good £4,727. These figures are significant when compared with the train mileage and passengers carried, 47,258 train miles more having been run, and 374,000 more passengers carried during the second half year, while the total expenditure has been £4 less, which reflects much credit on both the general manager and engineer, Messrs. T. C. Jenkin and Basil Mott, for the manner in which the working of the line has been conducted. It is to be regretted that this meeting was not a few weeks later, when the results of the present half year would have been available for comparison, but to date, since the opening of the line, the total mileage run is over half a million miles, and the number of passengers carried upwards of seven millions. The percentage of expenditure to receipts may appear high, but careful study and analysis of the figures show that this is not abnormally due to the traction expenses—the cost of locomotive and generating power, including salaries, office expenses, general superintendence, running expenses (including wages connected with the working of locomotive and generating engines, coal and coke, gas, water, oil, tallow, and other stores), repairs and renewals, including wages and materials, only amounting to 40 per cent. of the total expenditure, or 30 per cent. of the gross receipts, which I venture to submit will compare favourably with any other mode of traction. From these figures it will be seen that the cost per train mile for the last half year was just under 8d., while under the sliding scale before mentioned the cost per train mile on the mileage run would have been 7·125d. But in the actual cost of 8d., drivers' wages and other items are included, which were excluded in the sliding scale, and if deducted, bring the actual cost down to 5¼d. per train mile. This, I think, will be generally admitted as highly satisfactory, especially when the serious increase of the train load (no less than 40 per cent. above that originally stipulated for) caused by the increased weight of carriages is taken into consideration, the total train load for the 5¼d per mile being 42 tons. The working of the plant and line has been both regular and satisfactory.

On no single occasion during the whole period that the line has been in operation has there been any accident or stoppage of the generating dynamos, showing conclusively the security and certainty with which electrical plant can be worked. Slight delays have occurred from time to time with the locomotives, but these have in almost every instance been distinctly due and traceable to the unexpected load and strain put upon them, and in spite of which the record of work done by these locomotives will compare favourably with that accomplished by steam locomotives. The average mileage of the locomotives in regular use during the past year has been no less than 27,000 miles, while on a well equiped steam road the average is 20,000 to 23,000 miles per locomotive. The success of the line is further shown by the numerous similar projects which have followed. Last year a Bill was passed through Parliament authorising the construction of the Central London Railway, a line seven miles in length, extending from the City to Bayswater, to be constructed in the same manner, and to be worked electrically on similar principles, but on a much larger scale. During the present session no less than six Bills have been presented applying for powers to authorise the construction of similar undertakings. Of these six Bills, four of which are applications for new lines, and two for extension of existing powers (including the extension of the City and South London line to the Angel, Islington), three have passed through both Houses—viz., the Baker-street and Waterloo line, the Great Northern and City line, and an extension to Liverpool street of the authorised Central London line. The Great Northern and City line, running from Drayton Park to Finsbury-pavement, is of exceptional interest, being intended to relieve the Great Northern traffic, and over which it is proposed to run the ordinary rolling-stock of the Great Northern Railway. The above Bills in the first instance were referred to a Joint Committee of both Houses appointed to consider the whole question as to the best method of dealing with the electric and cable railways schemes, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic. The Joint Committee, after having met on several occasions, and having had submitted to them a large amount of evidence, reported strongly in favour of the various schemes, and with regard to electric traction, as follows:

"The committee report that the evidence submitted to

them was conclusively in favour of the sufficiency and special adaptability of electricity as a motive power to the proposed underground tubular railways."

It may therefore be assumed that before very long this system of transport will become fairly general in London, affording as it does a cheap, rapid, and safe mode of conveyance.

On the table is a small model of the Bessbrook and Newry motor-car; also a model locomotive of the same power as the City and South London line and but little more in weight, with Hopkinson's patent double motor, in which a single magnetic circuit embraces both armatures, the motors being carried entirely from the framework, and therefore on springs, and driving the axles by diagonal connecting-rods, according to a plan devised by the late Mr. Lange, of Messrs. Beyer, Peacock, and Co., Limited. The photographs round the room are various views of the plant, etc., of the Bessbrook and Newry and the City and South London lines.

Mr. SCOTT RUSSELL asked why a separate motor had been adopted. He thought otherwise a great deal would have been saved and greater adhesion obtained. He considered that all concerned in the City and South London line deserved the greatest credit for the success achieved.

Mr. A. J. JARMAN said that when the armatures were wound on the axles, the latter were turned into part of the magnet with the wheels, thus forming the pole, and clinging to the rail; hence, no sand was required to assist in starting. Another point was why the motors were wound in series. Supposing that one of the main wires become cut or broken, that motor would stop. If, however, the motors were wound in parallel, there would always be one leg of the field magnet to work, but worked in series with series winding that motor would be cut out. Winding in parallel had many advantages over winding in series in working the machine on gradients. He was alluding to tramcar traction, and he considered it would be more advantageous to wind the motors in parallel than in series.

Mr. RECKENZAUN stated that great credit was due to all concerned in constructing the City line, which was the pioneer line in that direction. With regard to operating expenses, he thought Mr. Grindle would have given details; how much was paid for coal and wages, etc. Taking 5½d. per train mile, the working expenses seemed very low indeed. He agreed with Mr. Jarman that if two motors on a locomotive or tramcar were placed in series, there was a possibility of their not working in union; if in parallel they worked together, and in case of accident one automatically cut itself out of circuit.

Mr. HOLROYD SMITH supported the remarks of Mr. Jarman and Mr. Reckenzaun on the matter of parallel working. From his own experience he had found a decided benefit by coupling up in parallel. It would be interesting to know the cost of producing one Board of Trade unit on the line. He would like to know whether any measurements had been taken to ascertain the relation between the electrical power put in the line and the mechanical efficiency obtained from it. Mr. Scott Russell had referred to the motors not being placed under the cars themselves. He (the speaker) said that if Mr. Russell had had the details of the line to thrash out he would have found that it was impossible to do so in that case. When the matter was fully taken into consideration, Messrs. Mather and Platt had decided upon the only safe way, considering the structure of the line, tunnel, cars, etc.

Dr. E. HOPKINSON, in reference to the separate motor or otherwise, said that in the case of the City line there was the difficulty of putting the motor on the bogie due to the restricted space, but that was a mechanical difficulty which could have been overcome with sufficient application. The total weight of the locomotive was 10 tons, and of the train 50 tons. Of the 10 tons the motors weighed six tons, and the saving by not having a separate locomotive would be four tons out of the whole 50 tons. If, however, the motors were placed on the framework, the bogie would have to be strengthened and made heavier, and the total saving would only be about two tons. Under those circumstances it was not worth while to do so, and that was ample justification of the plan which had been adopted on the South London line. Mr. Grindle, who came to his firm in Manchester seven years ago, suggested that that railway was the place for electrical work. That gentleman urged them to turn their attention to it, and the result was the working out of the details. With regard to having the motor in series or in parallel, from an electrical point of view there was nothing to choose between the two. It was a great mistake to suppose that having the motors in series would reduce the risk of a breakdown.

Mr. JARMAN stated that what he meant was that each pole of the field magnet should be wound so that they might be coupled in parallel and joined in series afterwards. That might be something new in motor work, but he had found it of great benefit in tramway work.

The next paper read was by Mr. L. EPSTEIN on

ELECTRIC TRACTION FOR TRAMCARS.

If possessed of no other merit I hope I shall be able to claim for my paper the merit of brevity, and I will endeavour to cover within the short space of time allotted to me—viz., 20 minutes—as long a line of track as the system of accumulators, which, with your permission, I am going to bring under your notice, will permit me. I will, to use an electrical expression, discharge my paper at a very high rate.

Having occupied myself for the last 12 years almost exclusively with the study and manufacture of secondary batteries, I had arrived, about two years ago, at a point which, not only by myself (who might be accused of the sanguine feeling inherent in inventors) but also by others upon whose common sense and clear judgment reliance may be placed, is considered to be as near perfection as any contrivance may be said to be. I have the pleasure of showing you here one of the accumulators which are specially adapted for propelling tramcars or other vehicles. You will see that this accumulator, unlike other cells, is composed of only three electrodes, which are contained in an ebonite box. There is no paste used in the manufacture of these cells, but the parts which are active—that is to say, which take up and give out again the electrical energy put into them—are produced out of the original substance of the lead itself.

To those gentlemen who take an interest in this matter I can show some plates here in the different stages of manufacture. The great point is that the so-called active material cannot by any possible means become detached, and that therefore there is no risk of material dropping off and damaging the accumulators when in use. There is also no danger from warping of the plates, which, as you will see, are very thick and robust, and therefore well adapted for the work for which they are intended. One of these cells complete, with acid, weighs about 45lb., and as generally 96 cells are used on a tramcar, the weight of the battery complete is a little under two tons, or about one-fifth of the total weight of the car, which, with its full complement of passengers, is a little over 10 tons.

This battery of accumulators will allow the car to run at an average speed of 7½ miles for about four hours, leaving a sufficient reserve in the accumulator to provide for any unforeseen emergencies. This running for four hours is under the assumption that the average expenditure of the battery is about 6 h.p., and the weight of the battery corresponding to 1 h.p. is, therefore, about 750lb. But if it should be desired, this battery can be discharged at twice the above rate, in two hours—that is, if provisions are made to exchange the batteries every two hours, the battery can be made to give out 12 h.p.—therefore the weight of the battery corresponding to 1 h.p., is, in this case, only about 370lb.

These accumulators have the further advantage that, if not required, they may be left idle for any length of time, without incurring expense. They are in this respect more economical than horses, which, as you are only too well aware, require fodder and attendance whether doing work or standing idle. Or, again, compared with horses, accumulators may lay claim to a much more certain and satisfactory state of health—glanders, skin diseases, pink eye, and other contagious diseases being unknown among them.

The further advantages are that the roadways are kept clean, there is no dirt or smell, and the cars are lighted at

the same time from the accumulator in a much more efficient manner than is the case now.

I am afraid I have already taken up too much of your time on matters relating solely to accumulators, and I will therefore pass to another point which may prove of more general interest. I am alluding to the question of £. s. d., and I will, with your permission, briefly glance at the cost of tramway traction by means of horses and the same by means of the accumulators which you see represented here by this cell.

The experience gained in the United States, and also some towns in England, has shown that an electrically-propelled car can complete several more runs per day than a horse car, as not only can they run faster, but the rest required by horses is of course absent in the case of electricity, and it has been found that electrically propelled cars have a proportionately higher earning capacity.

I have prepared some tables which will enable you to compare at a glance the relative merits of the two systems. In this table* (Table A) the costs of working a car mile find expression. You will see that if we call the cost per car mile worked by horses 100, the cost per car mile of the same line, if worked by means of our accumulators, is expressed by the figure 67, or, in other words, that a saving of about one third is effected in the latter case.

The next table, Table B, shows graphically the percentage of total working and general expenses as compared with total receipts. If we express the total receipts by the figure 100, the total expenses in the case of horses amount to a little over 75 per cent., while the total expenses with accumulators only amount to about 54 per cent. While, therefore horses, appropriate more than three quarters of the total receipts, the equivalent figure with accumulators is only a little over half.

In Table D the balances available for dividends are shown, and, as will be seen, the £50,000 available with horses are increased to £141,000 in the case of accumulators. The last table (Table D) shows a comparison of the dividends – 8½ per cent. in the case of horses, and 25 per cent. in the case of accumulators.

I am aware, gentlemen, that these figures will, perhaps, meet with some doubt, and that the remark will be made that however well they may look upon paper, very different results may accrue when put to actual test, but there is really no reason to doubt that these figures – at least, very nearly – express the truth. The cost of not only the accumulators, but the whole of the electrical installation has been carefully worked out, and will stand the test of rigid examination. If the estimate errs at all, it will, I think, be found to err on the safe side.

Now with regard to the expenditure. The cost of working is based on figures derived from actual running. The cost of fuel is well known. The depreciation of the boilers, engines, dynamos, and motors is liberal; therefore, the only item that might be open to doubt is the cost of renewal of the accumulators, but also on this point I think proof can be adduced that the estimate is a safe one. Our accumulators have been tested under conditions which are much more severe than those which they will encounter when in use on a tramway. They have been discharged at much higher rates, they have been left idle both after a charge and after a discharge for periods up to three months – all this without being damaged, so that there is really no reason to anticipate that the cost of maintenance will be more than, at the outside, 1d. per car mile.

Looking at it from the point of view of the manufacturer, this can be further explained by the fact that where accumulators of this type are being used, they only require the renewal of one plate, which plate is produced by casting, and as the lead of the old plate is recoverable, only a very little additional expenses for loss and wages is incurred.

Before concluding, I will just glance at the relative merits and demerits of the accumulator system and the overhead or trolley system, and the system of underground conductors. These systems can claim a less weight of car, but this is the only advantage as far as the trolley system is concerned; while, on the other hand, it possesses many, and some very great, disadvantages. Among them may be mentioned unsightliness of the overhead structure, the danger consequent upon the snapping of a wire, the impediment in case of frost (when the wires are frequently covered with a thick crust of ice, and the trolleys, therefore, make very imperfect contact), and the flooding of the rails (conveying the return current after heavy rains, when special cars have to be sent out to sweep the roadway).

The first cost of the two systems is about the same, but the efficiency of a good accumulator system is far higher than the efficiency of a trolley system. A calculation based on the working of the different lines on the trolley system in the United States has elicited the remarkable fact, that the efficiency—viz., the proportion of the brake horse-power on the car motor, as compared with the indicated horse-power at the generating station—amounts in some cases to only 25 per cent., and exceeds in no case 40 per cent. in everyday practice, or an average of 32 per cent.

The correctness of these figures will be easily recognised when we bear in mind that the generating station must be capable of furnishing the maximum current at any given moment, while the average current falls far short of the maximum, and as it is well known an engine works most economically near its maximum load, and less and less economically with a decreased load, the correctness of the figures, which at first sight may appear rather startling, will soon become apparent.

Although I have not so many figures at my disposal regarding the efficiency of an underground system, yet, as the conditions of working are almost identical with those on the trolley system, there is no reason to assume that the efficiency of such a system is any higher. A further great disadvantage of the underground conductors is that the construction of the line is very expensive. Both systems, the trolley as well as the underground, have the great disadvantage that where existing lines are to be converted into electrical lines the conversion interferes with the existing traffic—in the case of underground conductors much more so than in the case of the trolley system; while, on the other hand, provided only that the rails are in good condition, a horse line may be almost instantly converted into a line driven by means of accumulators.

With an accumulator system the efficiency is much higher than with either the trolley or underground system, and it will, I presume, interest you to learn the results of some experiments which were carried out at our works, under rather severe conditions. The batteries were discharged in three hours, and were charged again in three hours, without the use of any intermediate resistance, thus utilising the whole of the current for the battery. We found that it was only necessary to charge the battery with a current that exceeded the previous discharge by 5 per cent., and the efficiency—that is, the total energy given out as compared with the total energy put into the cells—under these very trying conditions was still as high as 78 per cent. Allowing for loss in dynamos, gearing, and motors, we arrive at the efficiency of 63 per cent. between the horse-power generated by the engines, and the brake horse-power on the car motors, and allowing 25 per cent. for the increased weight of the accumulator car we arrive at a total efficiency of 47 per cent., as against 32 per cent. of the trolley system. The explanation may be found in the fact that in the case of accumulators the central stations, which need not be so large as in the case of direct current, can always be used at their full capacity, no fluctuations of the output taking place, and the engines working much more economically.

Another great advantage is that each accumulator car is self-contained and independent of the central station, so that any breakdown at the central station does not interfere with the working of the line, while with the direct current, whether it be conducted to the car by means of overhead wires or underground conductors, an accident at the central station may interrupt the traffic on the whole of the line, and bring all the cars on the road to a standstill.

I hope to be able, at no very distant date, to supply you with figures derived from the actual working of our accumulators on different tramways.

* These were coloured diagrams, which the text fully explains.—

Mr. CARRUTHERS WAIN remarked that Mr. Epstein had made some statements in his paper which he would like to see practically carried out.

Mr. H. W. BUTLER, of the Electrical Power Storage Company, stated that his company could bear out all that Mr. Epstein had said as regarded the efficiency and useful work. He was always glad to find other people working in the same direction as the Electrical Power Storage Company. The latter was prepared to undertake the maintenance of accumulators at a very reasonable figure, according to the amount of work they had to do and the grades of the lines. Any tramway engineers who were sceptical as to the renewals question could rest assured as to the expenditure on that item. The tests made by Mr. Epstein were no doubt very stringent, and he doubted if the efficiency mentioned could be maintained.

Mr. RECKENZAUN said that Mr. Epstein's paper was very interesting as regarded the paper figures, but it contained nothing but hypothetical statements. He believed the accumulator to be a good one, but it had never been tested on a tram line. That battery might give 78 per cent. in the laboratory, but not in practical work. He believed that with the best modern appliances the average efficiency would be from 35 to 40 per cent. Statements made of 47 per cent. efficiency between car axle and steam engine were much exaggerated. He believed there was a great future for an accumulator which cost only 1d. per car mile.

Mr. L. EPSTEIN, in reply to Mr. Carruthers Wain, stated that his company was prepared to supply and maintain accumulators at a fixed sum for a certain time. The efficiency of 78 per cent. was arrived at when the accumulators were charged in three hours without any regulating assistance. The efficiency, when charged in five hours, was 82 to 84 per cent.

The last paper was presented by Mr. A. J. JARMAN, A.I.E.E., on

ELECTRIC TRAMCAR TRACTION.

Twelve months ago I had the pleasure of reading a paper before you upon that method of electrical traction that bears my name, and after giving you a detailed description of the mechanism and storage battery connected with this system, I promised to give some further information upon the practical working of the battery when we met together again. I am now able not only to give you some information respecting the everyday working of my patent storage battery, as well as that of another well known make, but also about the working of the electric motor, gearing, etc., which I fully described to you just a year since.

Towards the end of last year an agreement was entered into with the Croydon Tramways Company for the running of electric cars fitted under my patents. It was contemplated to run a regular two-car service, but with only two cars at my disposal, one alone could be kept in regular work; it being necessary to have one car ready to take the place of the other, when this had to be taken to the charging station to recharge the batteries. Had the charging station been at the end of the line a two-car service could be maintained, and time kept with three cars, but, situated as the charging station is, in the middle of the line, it would require four cars to maintain a regular two-car service, but these four cars could, with the depôt at either extremity of the line, maintain a three-car service, allowing one car in reserve. Before entering upon the account of the work done, I may state- and I trust the chairman of the Croydon Tramways Company may not disagree with me—that the conditions under which the running took place were not the most favourable. The flanges of the car wheels were too deep for the rails, and had to be ground down in running before the cars could run smoothly, the tread of the wheels being three sixteenths above the rails owing to the wheels having been made to suit another section of tram rail; the points, also, were not good enough for the electric cars, which would not occasionally take the points and consequently run off the line. These circumstances, as you understand, were not favourable to the cars, and much extra power was consumed and the motive machinery was subjected to strains which would not have come upon it on a line prepared for electric traction.

The first car commenced to run in everyday service in January of the present year, and ran for several weeks, carrying a considerable number of passengers—I remember on one occasion as many as 84. Well, after several weeks running, the vulcanised fibre teeth (which I used in my gearing wheels and which I adopted with a view to noiseless running) gave way, the mishap occurring through reversing the electric motor, and bringing the car up to a dead standstill whilst running at its normal speed so as to avoid running over a horse which had strayed across the tram line at night, and at a very dark part of the road; the life of the horse was saved at the expense of the car gearing. On examination of the wheels fitted with the fibre teeth, I came to the conclusion that these teeth were not adapted for everyday work. Upon careful examination it was found that these teeth had commenced to laminate, the lamination being caused through their running constantly in oil, to keep them well lubricated. In all the previous experimental runs, extending over a year or two, a mixture of tallow, lard, and plumbago was employed as a lubricant, and with this lubricant no defect was observed to take place with the fibre teeth. I took out all the vulcanised fibre teeth and replaced them with hard gunmetal; these teeth worked well, and I did not observe any perceptible increase in noise by their adoption. Last Easter Sunday one of the cast-iron mortice wheels fitted with these teeth broke in the main body into four pieces, all the gunmetal teeth remaining intact. I cannot now avoid coming to the conclusion that cast iron in any shape or form is not suited for the gearing of self-propelled vehicles, no matter how thick it may be employed.

Cast iron cannot withstand the shock and concussion which it must inevitably be subjected to in tramway work. Cast-iron mortice wheels were used only in the gearing of No. 1 car, not constructed by me; the gearing in No. 2 car, which was designed and put together entirely by me, was fitted with wheels cast in phosphor bronze, known as No. 7 alloy, and these wheels I have found to perfectly withstand the shock and strain incurred in tramway work, so far without becoming brittle or crystalline in their structure. Although I had allowed ¼in. for the side play of the mortice wheels and wrought-iron pinions, it has been found from everyday practice that a greater space should be allowed, particularly for the rounding of a curve, and the occasional crossing of the wheels when running over very much worn points, and this practical result leads one more than ever to adopt the simple and plain form of tooth for gearing which I have always advocated in place of either helical or worm gearing, as the side play of the car axle must impose a considerable side thrust upon the worm wheel and screw, and upon the sides of the teeth in helical gearing, and result in great friction, and consequent loss and waste of power.

There cannot be any doubt that some tram lines are very much heavier to run upon than others, particularly so where the groove in the rails is shallow, and becomes filled with dirt, thus absorbing an enormous amount of power in grinding the dirt to powder through the difference in the circumferential velocity of the flange of the car wheel to that of the tread. This applies to every method of traction upon tramways where a flanged wheel and grooved rail is used. The phosphor-bronze alloy of which I have spoken is capable of bearing a strain of 16 tons per square inch, and the gunmetal teeth 14 tons per square inch, these latter teeth working very satisfactorily with a wrought-iron pinion when kept well lubricated by dipping into the well-known green oil so much used for tramcar axles.

Having given you my experience with the gearing of the cars, I wish to say that it has been with this part of the mechanism that the principal difficulties have been experienced, and now this difficulty has been entirely overcome. I now come to the electric motor, and this, like the gearing, has been put thoroughly to the test, and I am very pleased to say it has withstood all the strains of everyday work that have been imposed upon it. It is true that one armature had to be renewed through defective insulation, but this was in car No. 1, the motor of which, as I have before mentioned, was not made by me. In every other respect

the motors have proved themselves perfect for tramcar work. Notwithstanding the heavy loads of passengers they have occasionally moved, they have been enabled to keep the cars up to their running time, and not interfere with the horse traffic, thus proving that they are equal to the task imposed upon them in carrying their loads, keeping time, and being both electrically and mechanically efficient, and demonstrating what is of vast importance to tramway companies—viz., that an efficient accumulator system enables the companies to gradually change the system from horse to electric traction without being burdened at the outset with the enormous capital outlay necessary for an installation by the direct-current system; at the same time my electric cars are equally applicable to a line worked by direct current. My patent carbon brushholder and the method of feeding the carbons as they wear away has proved itself a success in every particular, running for six weeks without renewal of carbons. An efficient little piece of mechanism like this is of the utmost importance where the electric motor is employed for traction purposes, as it enables the motor to run quite sparkless at the commutator.

I now come to the storage battery, and as I promised a year ago to say something about this much abused and less understood electrical accessory I will redeem my promise. It is but a few years back that the cost of traction by accumulators was an unknown quantity, but to-day all is changed; in fact, I think I may say that the cost of accumulator traction has become a known quantity since my paper was read before you 12 months ago. You will remember, in the concluding statement of that paper, I said "the cost of maintaining the batteries in an efficient state, from what I have before mentioned, I do not think will exceed in a large installation 1d. per mile." Speaking now from experience, I estimate the depreciation and renewal cost upon 104 battery elements, being the number used in my cars, at 1d. per car mile run. If confirmation is required of the correctness of my estimate, I think it is afforded by the fact that a large firm of storage battery makers are prepared to maintain the batteries they supply for traction work at a penny per car mile run, with some small percentage upon receipts or profits, thus amounting to just about 1¼d. per mile for depreciation, and this only goes to support the calculations I made a long time previous, and also what I have been able to ascertain in practice upon the Croydon Company's line.

There has not been a single battery element renewed in either of the two cars at Croydon from the day they started running, and I am strongly of opinion, based upon observation, that there is more harm done to the storage battery when standing idle than when it is in daily use, because the acid solution has more time to act chemically upon the spongy metal, and the subsalts that are formed, than it would do in everyday charging and discharging. I attribute in a great measure the lasting qualities of the accumulators in these particular cars to the good quality of the electric motor, and to the fact that the flow of current is small compared with other motors to start the loaded car from the state of rest, and thus the cells do not become over-discharged, as has been the case hitherto. My motor has been designed to suit the storage battery and to make it enduring, and practice up to now has confirmed my contention that I have attained this desirable end.

I now come to that part of the subject with which you all are more interested, and that is, what does the accumulator system cost to work, and will it pay? Upon this point I will be as exact as I can, basing my estimation upon actual practice, because I do not want you to suppose that my enthusiasm is so strong as to lead me to think that because a tramcar can be moved and propelled by electricity that that is all that is desired, nor to think that all the horses are to be wiped off the face of the earth because the question of electrical traction has made such great progress; I have stated before, and I state again, that this method of traction by electricity will stand only by virtue of its commercial value. Now the principal items of cost are: 1. Fuel. 2. Renewal of batteries. 3. Wages. 4. Repairs and renewals—oil, grease, and stores.

Now I found from experience at Croydon that the fuel consumed, using a double-cylinder, high-pressure portable engine (an expensive consumer) was 1½d. per car mile run on a wet day, up to 2d. per car mile run on a dry day. With dear fuel and such an engine, this cost is far higher than would be the case with a modern-type engine and running a number of cars. As to the cost of fuel, I think we may safely take the figure named in the *Electrical Review*, 20th February, 1891, as to the cost of fuel on the Barking line—viz., 1·033d. per car mile run over 100,000 miles. The wages per car mile run I am unable accurately to fix, but as the wages on our large horse tram lines, where necessarily a large number of men are employed as horsekeepers, etc., amount to less than 1d. per car mile run, we may be certain that the wages on an electric line would be far less. The cost per car mile of the renewal of batteries I have already treated of. The miscellaneous expenses, such as depreciation and repairs, oil, grease, etc., I will put down at another 1d., and in stating this figure I am again supported by the published figures of the Barking-road running before alluded to, although more than half of this 1d. per mile—viz., ·599d. per mile—comprised in that instance repairs to motors and gearing, a rate which I may confidently state would not be reached with my system. We have thus per car mile run:

Fuel	1d.	Total 4¼d. per car mile run
Renewal of batteries . .	1¼d.	
Wages	1d.	
Renewals, repairs, and sundries .	1d	

One thing has been found at Croydon, and that is the public take to these electric vehicles. They like the easy riding; they like their rapid travelling, which so often has enabled persons to catch their trains; they like the well lighted interior and the general advantages these cars offer. Considering, moreover, the fact that they carry heavier loads of passengers than horse cars, it is evident that they can be made to pay well upon the lines where they may be adopted where horse cars would not pay, and that 90 miles per day could be run by these cars just as well as 70. There are many tram lines in this country that never have been worked at a profit and never will be where horse traction is employed. Those that have invested their capital in the laying down and equipping of these lines have long seen that their salvation lies in cheaper traction. I am convinced that if there is one force more than another that will prove effectual in accomplishing this desired object, that force is electricity.

Unforeseen difficulties always have arisen in the development of every invention and industry. We all have to learn and be taught by that one great master—experience. The self-contained electric car embodies all the elements for successful working. It matters little what may have been done in the past or what errors may have been discovered in the early stages of experimental work for the propulsion of tramcars by electricity. Depend upon it, the time will assuredly come when the accumulator car will take a firm footing upon our tram lines because of its many advantages over every other form of traction.

In the evening of Tuesday the members inspected the Electrical Exhibition at the Crystal Palace, where the annual dinner subsequently took place. On Wednesday a party of members visited the City and South London Railway and inspected the electrical plant and generating station; and afterwards they witnessed some experiments with the Connelly motor at the depôt of the London, Deptford, and Greenwich Tramways Company, at Deptford.

Cheap Batteries.—We hear accounts of experiments with a coal battery—that is, a battery using up coal in its solution—from an enthusiastic inventor who thinks he has got hold of the right thing at last. We should like to have the results of the tests. We have further been favoured with the sight of the patent by Harris and another (not Mark Twain) of the arrangement for producing what we have termed "tinpot" electricity. Water forced slowly through a brimstone diaphragm fixed in a tin vessel will, says the specification, produce a difference of potential by simple molecular action. It would be certainly interesting to see it done.

STEAM AND GAS ENGINES AT THE ELECTRICAL EXHIBITION.

The display of electrical applications in the Crystal Palace Exhibition shows the great importance of the part played by the various kinds of motive-power engines which are employed in driving the many types of electrical generators. The steam engine still occupies the most prominent position, but gas engines are only second for this work. Almost all the makers of this type of motor are represented, and it is clear that for a large proportion of all the smaller electric lighting installations the gas engine is and will be used. The effects of the variation in rotative speed have to some extent been eliminated partly by the adoption of much higher engine speeds, and partly by the use of flywheels on the electric generators which they drive. Where very great regularity is required or deemed to be very essential the steam engine will long continue to be the favourite motor, but the advantages which attach to the gas engine will in very many cases outweigh very great precision in this respect

The time is no doubt rapidly approaching when economy in cost of working will be added to the other advantages which the gas engine offers, and it is conceivable that future improvements will enable the gas engine to be run with much greater regularity in rotative speed than at present. To those causes of improvement in this respect will probably be added greater precision in governing and a more general employment of systems of working which secure impulse at every revolution, or possibly at every stroke. All these systems of working are even now represented by engines in the Palace, and experiment and experience will, no doubt, gradually point the way to obtain the greatest economy with engines which also secure the greatest regularity. While remembering that the steam engine is, for large powers, still the most economical motor, it has to be admitted that the gas engine supplied with heating-gas made specially for the purpose—as, for instance, on the Dowson system—is the most economical motor yet made, even for very large powers. The steam engine cannot be relied upon to give an indicated horse-power for less than 14lb. of good coal. The gas engine, with Dowson gas, and of not less than 20 h.p., can now be relied upon to give an indicated horse-power for 1·2lb. of coal, and gas engines are being made which are capable of giving off approximately 100 h.p. At present, the only objection to the gas-making plant for this purpose is that it involves attention which corresponds with attention to a steam boiler. The oil engine, which is now beginning to take an important place among small motors, is not represented in the Exhibition, apparently because these engines cannot at present be worked without giving rise to disagreeable smells, which, though not sufficient to prevent their use in many places, would be objectionable in a building like the Crystal Palace. No other cause for their non-appearance in the Palace can be assigned, inasmuch as oil engines are now made which employ oil having a high flashing point. The only other type of motor at all extensively used for driving electrical generators which is represented in the Palace, is the turbine. For these and other hydraulic motors there is no doubt a prospective field for electrical work in Scotland and Ireland, and to a smaller extent in England, but not sufficiently immediate to make it necessary to refer at length to them now.

The steam engines comprise almost every type commonly applied in electrical work, including the single-acting engines, both compound and triple, represented particularly by the engines which Messrs. Willans and Robinson have made so popular; the ordinary double-acting engine with single cylinders and compound, represented by the engines of the Brush Company, Easton and Anderson, Scott and Mountain, Ronald Scott and Co., Holmes, and several others, as already illustrated in our issue of April 29. The triple-expansion engine is well represented by the fine engine of Messrs. Davey, Paxman, and Co., coupled direct to the large eight-pole Johnson and Phillips central station drum armature machine running at 130 revolutions per minute, as illustrated in our columns of April 15 last. This is a remarkably well-made engine of the marine type, with cylinders of 12in., 18¾in., and 30in. diameter, all with a stroke of 18in., the engine indicating 350 h.p. with steam at 160lb. pressure, when running at its intended speed of 140 per minute. Working at its proper load, this engine would probably give an indicated horse-power for about 15lb. of steam at the pressure named. It is fitted with Paxman's double valve and link cut-off controlled directly by a governor, which secures great precision of cut off and regularity of speed and rotation. It forms one of the chief features in the steam-engine part of the Exhibition, but there are numerous other steam engines of a different but nevertheless important kind, to which we must refer at length in a future issue. They include the Willans central valve engine, one of which was illustrated in our issue of the 29th of April; the engines exhibited by the Brush Electrical Engineering Company, by Messrs. J. H. Holmes and Co., and several others.

Amongst the gas engines to which a very high place must be given, must be mentioned the high-speed engines of various sizes exhibited by Messrs. Crossley Bros. These engines work on the well-known Otto cycle, but are specially designed to run at a high speed, so as to secure regularity of rotation, and are provided with governor gear and timing valve to suit them for electrical work. These engines are, we may further mention, now fitted with self-starting gear, by means of which engines, even of considerable size, may be started without difficulty. A different type of gas engine is shown in several sizes by Messrs. Campbell and Co., of Halifax; still another type by the Griffin Gas Engine Company; another by the British Gas Engine Company; another by Messrs. Day and Co.; and another by the makers of the Stockport engine. All of these are of different types, and we must postpone reference to them to another issue.

LONDON COUNTY COUNCIL.

At the meeting of the Council on Tuesday the adjourned report of the Highways Committee on the Victoria-embankment lighting was considered. The report says: "Our attention has been directed to the defective lighting of the Victoria-embankment, and especially of the carriageway, and for some time past we have had under consideration the desirability of substituting electricity for gas as the illuminant. In connection with this substitution the first question that presents itself is what method should be adopted to provide the supply of electrical energy; and three courses appear to be open for adoption—viz., (a) to obtain the supply from the companies authorised to supply within the areas in which the Embankment is situated; (b) for the Council to lay the mains and provide and fix the lamps, and then to obtain the supply from one of the companies; and (c) for the Council to instal the necessary plant on its own land and to light the Embankment by means of an independent installation. The first course (a) is open to the objection that three several companies would have to be dealt with—the City of London, the Metropolitan, and either the London or the Electricity Supply Corporation—and considerable complication might arise, as one part of the Embankment might be efficiently supplied, while others might not, and, moreover, as each company would have to lay mains for the portion within its own district the cost might be increased. The second course (b) is open to the objection that although the Council would provide the mains, and would not apparently be prohibited from carrying the current from one company's district to another, the other companies might consider that this course, although probably legal, was straining the strict interpretation of the Acts. The third course (c) appears to us to be the proper one for the Council to take, having regard to all the circumstances. The first capital expenditure would, of course, be greater, but the cost of maintenance would probably be less, and the adoption of this course would accord with the principle which has been affirmed by the Council of the carrying out of work by its own staff when practicable. Should the Council decide to adopt the electric light as the illuminant for the Embankment, we propose that lamps of from 1,000 c.p. to 1,200 c.p. should be placed in the centre of the road at about 50 yards from each other. About 30 of these lamps would be required for the carriageway, some few of which at important points might be of a higher illuminating power; and the supply of the electric light might also be extended to the existing lamps on the parapet walls, and, where necessary, to those on the footways. The generating power required for this installation might conveniently be placed upon the land belonging to the Council under the Charing Cross railway bridge; and for the purpose of ensuring against the extinction of the light through the failure of any part of the machinery, and also as an economical precaution, the light should be placed on two independent circuits, an engine and dynamo being provided for each circuit, and a third engine with dynamo being kept in reserve to be available, if required, for either circuit.

Steam could be supplied by a boiler of the locomotive type, and a second boiler should be kept in reserve for use if required. The mains could be so arranged that at midnight, or at any other time that might be fixed for the purpose, the lamps on one circuit could be extinguished leaving the Embankment less brilliantly but yet sufficiently lighted. Upon the question of cost, we are advised that the capital expenditure if the above arrangement were adopted would probably not exceed £10,000, while the cost of maintenance, including depreciation, repair, and interest on capital, and also providing amply for labour, would probably not exceed £2,000 per annum. It may be stated that, with a comparatively small increase on the capital expenditure above stated, provision might be made for the lighting of the Embankment gardens and of Westminster and Waterloo Bridges; but this is a matter which could afterwards be dealt with by the committees concerned. After full and careful consideration of the facts, and of estimates put before us by the Council's officers, we have come to the conclusion that it is desirable that the electric light should be adopted as the illuminant for the Victoria embankment, and that the Council should itself undertake the work in connection therewith. We accordingly recommend—

> "That, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, it be referred to the Highways Committee to carry out, at a cost not exceeding £10,000, an electric installation with the necessary plant for the lighting of the carriageway, footways, and parapet walls of the Victoria embankment."

Mr Grosvenor, on behalf of the Bridges Committee, appealed to the chairman of the Highways Committee to establish plant on such a scale as would permit of the bridges which abut on the embankment being also lighted by electricity.

Mr Benn, in reply, stated that if Mr. Grosvenor would bring forward an additional estimate of £2,500 or £3,000, the Highways Committee would be very glad to join hands with the Bridges Committee and light the bridges as well as the Embankment.

Mr. Beachcroft moved, and **Major Probyn** seconded, that the report be referred back for further consideration.

After some discussion the recommendation of the committee was agreed to with the following addition: "And that the Highways Committee do also confer with the Bridges Committee and Parks Committee respectively, and report whether the plant can be established on a sufficient scale to enable Westminster and Waterloo Bridges and the Embankment gardens to be lighted from the same source.

COMPANIES' MEETINGS.

WEST COAST OF AMERICA TELEGRAPH COMPANY.

The fifteenth ordinary general meeting of this Company was held last Monday at Winchester House, 50, Old Broad street, Mr. Henry Roberts presiding.

In moving the adoption of the report, the **Chairman** spoke in terms of regret of the death of the late chairman, Mr. Alfred Marshall. With reference to the report, their gross earnings, although showing a very large decrease as compared with those of the previous year, might be considered satisfactory when all the circumstances were taken into consideration. The year under review was ushered in with the revolution in Chili, which was not terminated until the end of August. The Company's cables were interfered with by both parties, but they were all repaired between April 17th and May 6th. Certain sections of their system were closed for public traffic by order of the Congressionalists and of the Balmaceda Government. The Company received some compensation for the suspension of their business until March 18th. With reference to the cutting of their cables they had preferred a claim for the expenses incurred in effecting the repairs, which had been charged to the revenue account. Their claim was now under the consideration of the Government of Chili. Negotiations with the Brazilian Submarine and the Western and Brazilian Telegraph Companies, conducted under the presidency of Sir John Pender, K.C.M.G., had been brought to a satisfactory termination, resulting in the formation of a new company. The share capital of the company, £100,000, would be held by the Brazilian telegraph companies and this Company. The line being worked for their joint benefit, and connecting, as it would do, the ports of Valparaiso and Buenos Ayres, would give them a connection with the Brazilian companies and the Eastern Telegraph Company over a line duplicated throughout, and opening up a rapid and efficient service between the west coast and Europe. The new land line was already in course of construction. The American Company, having acquired since January 1 last the existing land line between Valparaiso and Buenos Ayres, had so adjusted the tariffs as to exclude this Company from participating in any European traffic at their principal stations, and this state of things would continue until the new line was completed, when the public would have the benefit of a service which would carry messages between Europe and the west coast of South America entirely over lines owned by English companies and worked by English operators. As to their earnings during the present year, it had been thought desirable, owing to the competition, not to publish or issue in any form the monthly receipts.

The motion was seconded by **Mr. Frederick Walters**, and adopted.

Mr. J. Denison Pender was afterwards elected a director and the retiring members of the Board were reappointed.

NEW COMPANIES REGISTERED.

Electrical Coal Cutting Contract Corporation, Limited.—Registered by Lake and Co., 10, Lincoln's inn, W.C., with a capital of £402,000, divided into 60,000 £5 ordinary shares, 20,000 £5 deferred shares, and 2,000 £1 founders shares. Object: to adopt and carry into effect an agreement expressed to be made between the Woodfield Syndicate, Limited, of the one part, and this Company of the other part, for the acquisition of certain patents, particulars of which are given in the said agreement; and generally to carry on, in all their respective branches, the business of colliery proprietors, coke manufacturers, coal cutters, contractors, electricians, electrical engineers, mechanical engineers, producers, and suppliers of electricity, etc. The first subscribers are:

	Shares.
Sir A. C. Campbell, M.P., Blythswood, Renfrew	105
L. Wood, J.P., Hermitage, Chester le Street, Durham	105
Hon. G. W. Winn, Nostell Priory, Wakefield	10[illegible]
J. R. Knowles, Westwood, Ince, near Wigan	[illegible]
S. Rivington, Kilmeny, Wimbledon, Surrey	105
W. T. Goolden, 28, Westbourne park	105
F. Stobart, J.P., Biddick Hall, Fencehouses, Durham	10[illegible]

Each of the above signatories holds 100 ordinary and five founders' shares. There shall not be less than five nor more than 10 directors; the first to be elected by the signatories to the memorandum of association. Qualification, five founders' and 100 ordinary shares. Remuneration not specified.

Pacific and European Telegraph Company, Limited.—Registered by Bischam and Co., 30, Old Broad street, E.C., with a capital of £100,000 in £10 shares. Object: to adopt and carry into effect an agreement expressed to be made between the Brazilian Submarine, Western and Brazilian, the West Coast of America, and the Pacific and European Telegraph Companies of the one part, and Sir John Pender, K.C.M.G., of the other part, for the construction and maintenance of telegraphic communication between Buenos Ayres, Valparaiso, and Santiago. The first subscribers are:

	Shares.
Sir J. Pender, K.C.M.G., 18, Arlington street, S.W.	1
Sir J. Anderson, 62, Queen's gate, S.W.	1
T. Fuller, 18, Chesterfield street, W.	1
A. Wood, Abbey wood, Belvedere, Kent	1
Lord R. H. Brown, Reigate, Surrey	1
R. Collett, 50, Old Broad street, E.C.	1
R. M. Cunningham, 19, Great Winchester street, E.C.	1

There shall not be less than three nor more than five Directors, and each of the above mentioned first three companies is entitled to nominate one Director for each 2,300 shares of the original capital of the Company held by them respectively. Qualification, £100. Remuneration to be fixed by the Company in general meeting.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,792.

Eastern Extension Telegraph Company.—The Directors of this Company have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, tax free, payable on 1[illegible] prox.

Messrs. Arthur B. Gill and Co.—Mr. Arthur B. Gill, trading under the above title at 36, Parliament street, Westminster, has filed a deed of assignment for the benefit of his creditors: debts, £5,831; net assets, £4,084.

City and South London Railway.—The receipts for the week ending June 26th were £747, against £697 for the same period of last year, or an increase of £50. The total receipts to date from January 1, 1892, show an increase of £1,257 as compared with last year.

Chili Telephone Company, Limited.—The report of the Directors of this Company to March 31, 1892, states that the business of the Company during the past year has been less profitable than that of the two previous years. This unfavourable result is due solely to the political and other abnormal calamities which befell the Chilian nation and affected adversely the affairs of the Company. The income from subscriptions and other sources which in in 1890-1 was 387,110dol., has fallen for the year 1891-2 to 378,830dol. The lines have been gradually, steadily, and as promptly as possible restored, and the subscribers re-connected with the exchanges, so that the number of subscribers now served is nearly, if not quite, equal to what it was before the civil war began. As the bulk of the increased expenditure has been caused by the revolution, a claim has been made against the Government, of which 115,000dol. remains unpaid. No part of this sum has been treated as an asset in the Company's accounts; whatever may be hereafter received from the Chilian Government will be credited to future revenue. The balance of profit in sterling for the year was £6,067, which, with the balance brought from last year, viz., £14,209, makes £20,276 available for division. As the profits have been used for capital purposes, they cannot be divided in cash, but the Directors recommend that deferred warrants be issued for 10 per cent. on the share capital, and that these warrants, at the option of the holders thereof, be accepted by the Company for ordinary shares, which will carry dividend from April 1, 1892.

Antidote to Mercury.—M. Friquet, who is engaged in the manufacture of lamps at Paris, states that iodide of potassium is an efficacious antidote to the trouble with mercury fumes sometimes experienced in the incandescent lamp pump-room. A daily dose of a quarter of a gramme in 400 cubic centimetres of milk is recommended.

Telephones for Vyrnwy.—The Liverpool City Council on Wednesday authorised the Water Committee to arrange by contract or otherwise for the requisite telephonic communication and other electrical appliances required between Liverpool and Lake Vyrnwy and between Liverpool and Rivington reservoirs, at a cost of not exceeding £4,000.

Brazil Telephones.—Telephonic communication will shortly be established, says the *Financial News*, between Rosario and Buenos Ayres, the installation costing about 300,000dols. gold. The lines will pass through Belgrano, San Isidore, San Fernando, Tigre, Baradero, San Pedro, San Nicholas, and will belong to a French company, who will use the Testu system.

Hammersmith.—A committee of the Hammersmith Vestry is to take under immediate consideration the desirability of applying for a provisional order for electric lighting, and taking the necessary steps for obtaining parliamentary powers to supply electricity for public and private lighting, with a report on the cost and the most convenient areas to be lighted.

Chelmsford.—At the last meeting of the Town Council, communications were read from the Board of Trade stating that they had given Messrs. Crompton and Co.'s agents notice of certain alterations which were necessary in the electric lighting arrangements at Chelmsford, and giving them two years in which to comply with the notice. The matter was referred to the Lighting Committee.

Awards. — The French Société d'Encouragement, besides the prize of 3,000f. to M. Hillairet, have awarded a gold medal to M. Hermite for his electric bleaching process; a platinum medal to M. Marès for his electric meter; a bronze medal to M. Legoaziou for his electric scrutator; and a commemorative medal to M. Hippolyte Fontaine for his paper on industrial applications of electricity.

St. Helens.—At the St. Helens Town Council on Wednesday, Councillor Leach asked the Parliamentary Committee to obtain a better service of trains between Liverpool and St. Helens, and also urged the importance of an omnibus service. This is the sort of opportunity which would be at once taken in America to run an electric street railway with an abundant and quick service.

City Electric Light Standards.—At the Commissioners of Sewers last week, Mr. G. Harris was anxious to know why some of the new electric light standards were of one shape and some of another. The City engineer replied that in the crowded thoroughfares it was thought better to have the round standards to economise space, but in other streets they had the full size square standards.

Incandescent Lamps.—The Cheesbrough flashing patents run out in October. We are to expect lamps at two shillings, or less, burning at 1½ watts per candle power for 400 hours after that date, so we are told. The 1½ watts efficiency would make it good for supply companies and customers alike, for the one could supply more customers, and the other would pay less for current. The "400 hours" is still problematical.

Postal Telegraphs.—According to a return of the revenue and expenditure of the Post Office Telegraphs for each year since the purchase, we notice that the estimate of the figures for 1891-2 show a total revenue return of £2,542,200, the estimated expenditure being £2,633,050. This shows a net revenue deficit of £90,850. To this should be added the interest on stock created for the purpose of telegraphs, which comes to £299,052.

Huddersfield.—The Gas Committee at the last meeting of the Huddersfield County Council reported that the Local Government Board had given their sanction to the borrowing of £50,000 for the purposes of electric lighting, £12,000 being for the necessary buildings, to be repaid within 30 years, and £38,000 for the general purposes of electric lighting, to be repaid within 15 years. The contract has been secured, it will be remembered, by the Brush Company.

Isle of Man Exhibition.—The Isle of Man Exhibition of Manufactures, Science, and Art was opened on Wednesday by the lieutenant-governor, Mr. Spencer Walpole. The exhibition is situated at the Bellevue Gardens, about a mile from Douglas. The buildings cover 100,000 square yards. One of the most prominent features of the exhibition is the model of the "Victory," which was exhibited at the London Naval Exhibition. The exhibition is lighted by electric light by the Brush Company.

Glasgow.—Tenders are required by the Glasgow Gas Committee for providing and erecting (1) steam engine and pipes; (2) dynamos, switchboards, and connections, and (3) arc lamps. Plans and specifications may be seen, and forms of tender obtained, on application to Prof. Kennedy, 19, Little Queen-street, Westminster, consulting engineer to the Corporation, or to the Gas Office, Glasgow. The various tenders will be received by Mr. J. D. Marwick, town clerk, City Chambers, George-street, Glasgow, on or before 12th inst.

Lacombe Carbons.—A new company, entitled "Le Carbone," have acquired the well-known carbon business of Messrs. Lacombe and Co., of Levallois-Perret, near Paris, and will continue the manufacture of carbons for electrical applications of every description. The plant will be extended, and the entire staff, as well as the services of M. Lacombe himself, have been retained by the company. The managing director is M. M. Blair. The London branch will remain under the management of Mr. J. O. Williamson.

The Lane Fox Case.—The appeal case of Lane Fox v. Kensington and Knightsbridge Electric Lighting Company has been heard and finished, the decision being held over. This case has instituted an interesting precedent, as the defendants' counsel, after full *viva voce* argument, put in a written summary of the points on which they relied. Thereupon Mr. Lane Fox was allowed to prepare and hand in a written statement of his own case. This concession involves a return to very early practice in pleading of the English Bar, and is likely to prove of great assistance in technical cases.

Punkahs. — Messrs. Jessop and Co., Limited, of Calcutta, have recently put down a whole installation of compressed air punkah-pullers in the Dalhousie Barracks, Fort William, including a 14 h.p. steam engine. Ten motors drive 619 punkahs. It would be thought that electric motors and fans would be equally or better suited for such a function, and if a 14-h.p. steam engine is worth putting down here, other large installations will be wanted. In India, coolness as well as light are required, and a large number of Government buildings are open for application. A little enterprise might result in good orders.

The General Election.—Electric light has played its part in the general election contest that has been upsetting both business and amusement during the past week. At the National Liberal Club, Messrs. New and Mayne, electrical engineers, of 12, Palace-chambers, Westminster, had

arranged a large board hung out from the tower fitted with incandescent lamps, and on these the results were flashed out in large capital letters and figures 4ft. high. A light at the top showed gains and a light at the bottom losses. The results were thus flashed out and could be seen and read by everyone far down on both sides of the river.

Electric Motor Controller.—The Thomson-Houston Company have long been experimenting with the idea of getting better control of tramway motors than the usual resistance. They have now brought out a controller with which they seem satisfied from the practical side, consisting of connecting switches for altering the connections of two-car motors from series into parallel, so that for slow speed the two motors will be in series, giving in consequence a high counter E.M.F. (that of each motor being in series with that of the other) at a low rate of speed, while for higher speeds they are connected in parallel. The Thomson-Houston Company claim to hold controlling patents for this class of apparatus, the most important being United States patents 385,055, June 26, 1888; and 393,322, November 20, 1888.

Small Alternate-Current Motors.—We hear that Messrs. Shippey Bros., the firm who have been well known as pioneers for the Crocker-Wheeler continuous-current motors in this country, are in the market with a new small alternate-current motor, $\frac{1}{8}$ h.p. and above, wound for 100 to 110 volts, a number of which have been already supplied and are working on the London Electric and City circuits, driving ventilating fans, sewing machines, and so forth. Messrs. Shippey Bros. are reticent at present respecting the details of the motors, but we learn that motors are being tested by several well-known electrical engineers. Alternate-current companies will await with interest the result of the experiments, which, if satisfactory, opens the field of profit for the use of current during the day.

Water Power in Sweden.—Mr. H. Aulin, of Norrköping, Sweden, advertises in the *Times* as for sale, in the centre of Sweden, a waterfall of about 3,000 h.p., in the Dalelven. This, he says, is very suitable under the most economical conditions for all industrial undertakings, such as installation of very powerful electrical generators. Situated near the Avesta railway station, in the south of the Dalarne province, in an important mining and industrial centre, it has communication with all the railway lines and ports of the country. The waterfall, dam, surrounding land, with 20 hectares agricultural land, 18 hectares prairie, forest of fir trees (85 hectares), necessary buildings, as well as flour mill and salmon fishery, are included in the sale. Here is a fine chance for some enterprising electrical engineer with financial backing — almost as good as Niagara, according to the advertisement.

Sulphur.—Herr Grop, of Berlin, has communicated to the Physical Society of that city, we read, some exceedingly interesting results of a series of experiments he has undertaken upon the composition of sulphur. He melted sulphates of barytes and of strontian in a crucible of silver, which served as one electrode, the second electrode being formed of a platinum wire dipping into the melted mass. After the passage of a strong current of electricity for a certain time, the experimenter proceeded to analyse the resultant mass. He found that the barium had combined with the platinum to form a compound unknown up to the present time, and stated at the same time that about 50 per cent. of the sulphur had disappeared to make place for 40 per cent. of still another entirely new compound. Herr Grop considers that he has proved that sulphur is not an element, but a compound of the new substance and hydrogen.

Cost of Club Lighting.—The London clubs have long felt the benefit of the electric light, but are now feeling the charges too much for their purses. A meeting of the secretaries of some of the principal clubs was held the other day at White's Club to discuss the question of the charges made by the electric lighting companies for supply of current. The following clubs were represented, all of which use the electric light: White's, Devonshire, Travellers', Windham, Reform, Orleans, St. Stephen's, Conservative, Brooks's, Junior Army and Navy, Thatched House, National, Oxford and Cambridge, and Prince's. A deputation from the meeting was appointed to wait upon the directors of the companies supplying these clubs, to request that a considerable reduction should be made in the charges, which, it was agreed unanimously, had become too onerous. The question is, of course, a purely business one between buyers and sellers.

Tivoli Transmission.—The Rome correspondent of the *Daily News* telegraphs on Wednesday: "At Tivoli yesterday were inaugurated, in the presence of the Minister of Posts and Telegraphs and a great many scientific men, the works for the electric lighting of Rome. A volume of 141 cubic feet of water, having a fall of about 164ft., is distributed between six turbines furnishing over 2,000 h.p. Besides these, three other turbines, each of 50 h.p., are destined for the dynamos. From Tivoli the electricity is brought by means of four copper wires in suspension over 712 steel standards to Rome, a distance of about 22 miles. The total loss of power is 20 per cent. A Budapest firm has furnished most of the machinery, and Austrian electricians have co-operated with Italian savants in solving the technical problems of the installation. Letters of congratulation from Prof. Silvanus Thompson and Messrs. Fleming and Preece, among others, were read at the ceremony yesterday."

Alternating and Continuous Currents.—The two rival factions of alternate and continuous-current advocates are possibly a little nearer amalgamation than they expected, if we are to believe the news which comes to us from an authentic source, with reference to an interesting series of experiments in France. Amongst those who are pushing forward the possibilities of the application of alternate currents in that country stand prominently Messrs. Hutin and Leblanc, whose experiments on motors and transformers we have followed from time to time in these columns. These gentlemen have recently been experimenting with condensers, a field of which great things may be expected shortly both in the application of alternate current to motors, and to the rectification into direct currents. We understand that experiments have been carried out showing that secondary cells can be charged by these rectified alternate currents at an efficiency for the current of 96 per cent. This result promises large things for alternate-current engineers.

Claybury Asylum.—Tenders are invited for generating plant and mains required for the installation of electric light at the London County Lunatic Asylum, Claybury (Woodford) Essex, for the Asylums Committee of the London County Council. Printed forms of tender, contract (with specification and schedules annexed) and bond, and lithographed copies of the drawings, can be obtained on application to the clerk, at the offices of the committee, 40, Craven-street, Strand, on payment of £5, which will be returned on a bona fide tender being delivered within the appointed time, or on return of the forms and drawings before that time. Schedules of prices and of rates of wages and hours of labour, etc., are to be attached fully priced out and

signed. The tenders are to be delivered at the offices of the London County Council by noon on July 26. The contractor will have to enter into a bond in £500 with two approved sureties in £250 each as security. Application to be made to Mr. R. W. Partridge, clerk to the Asylums Committee.

New Brush Dynamo.—The following particulars are given in the New York *Electrical Engineer* of the Brush Electric Company's new dynamo and motor: They have been designed by Mr. S. H. Short, chief electrician to the company, and the generator takes 100 h.p. on the pulley. The armature is of the closed coil type, with core of thin sheet iron riveted on a foundation ring, the edges of this ring being milled to allow for bobbins. The wires leading from the armature to the commutator are carried along the shaft, and are carefully covered to protect from dirt or damage. The bearing on the commutator side is placed outside the commutator to allow a clear way for connections. The generators are compactly built, and the ventilation is perfect. Any part can be inspected without disarranging other parts, and in case of accident armature or magnets can be easily removed for repair. The motor of this type requires no outside governor, being perfectly automatic in action. They are wound for 1,000 volts for transmission of power over small wires. The new type of commutator, with which both generator and motor are fitted, runs practically with no sparking.

Handsworth.—At the meeting of the Handsworth Local Board on Wednesday Mr. J. J. Hughes presented the Highway Committee's report, which recommended the Board to sanction the present steam arrangements on the South Staffordshire Tramways Company's cars for a period of six months, to be extended for a further period of six months on the company undertaking to adopt an approved system of electric or cable motive power. The committee also recommended the Board to consent to the use of steam by the Central Tramways Company on their Birchfield and Lozells route for 12 months. Mr. Henry Hossell, in seconding the adoption of the report, said he hoped it would be the last time he would be asked to give his consent to the use of steam. The ratepayers were very much annoyed at the abominable nuisances which existed, and if the Board did not take some sort of action they would take action themselves. He had no hesitation in saying the property in the Birchfield road had depreciated to the extent of £10,000, and houses in that neighbourhood were now let at £10 which formerly used to realise £60 per annum. The report was adopted.

Catalogue.—We are in receipt of the catalogue of the Newton Electrical Engineering Works, Taunton. This company make a speciality of their "Taunton" dynamos, which we have several times noticed. These are of an inverted two-pole type and of good design. The catalogue shows a combined Priestman oil engine and "Taunton" dynamo—a useful combination for country house. This company have some useful specialities in the way of adjustable brushholders, in which by means of a milled screw the brushes can be accurately adjusted during running. Their automatic charging cut-out is a neat and useful piece of apparatus, and the "Newton" arc lamp is very simple and cheap. A quite novel piece of apparatus is a swinging switchboard for use in central stations or other installations. The wires come up a central hollow standard, and are arranged with slack wire so that they permit the switchboard itself to be swung forward on its hinges when required for inspection or alteration of connection. The swinging switchboard can be locked into place when all is fixed, and it is claimed the advantage in case of handling more than compensate for the slight extra cost. The company also make their own alternate-current transformers.

New Street in London.—Sardinia-street central station is apparently threatened with extinction by the new and comprehensive scheme for a new broadway between Holborn and the Strand, brought in by the Improvements Committee of the London County Council. This, however, may be a mistake or misreading of their project, and perhaps the station can be arranged to be left; but the idea seems to be to form a new and broad street from Little Queen-street and Holborn to St. Mary's Church in the Strand, to remove the Holywell block entirely, and on the northern side, where the new street will come out, to form a double sweep in a curve round the church, thus forming a magnificent chance for architectural decoration. The new street is to be 100ft. broad, and at the middle, it is stated, on the present site of Sardinia-street, a circus will be formed, obliterating the whole of the present district. The scheme will cost £2,000,000, and will certainly greatly improve the metropolis. The chance should be taken to put in electric wire subways, so that in one street at least we may be saved the trouble of constantly opening the roadway and pavements. The street will naturally be fully lighted with arc lamps. It is suggested to call it "Council broadway."

University College.—The Council of University College, London, have been desirous for some time past of extending and improving the provision made in the college for teaching the important practical sciences of mechanical and electrical engineering. University College, London, was the first college in the United Kingdom to establish a system of scientific laboratory instruction in mechanical engineering. In that laboratory methods of teaching were introduced by Prof. Kennedy which have been since extensively followed in other similar institutions, and the engineering laboratory so established in University College, London, has proved a model for larger and better equipped laboratories which have been founded in other colleges. Owing, however, to the rapid advances in mechanical, and especially in electrical engineering, the present provision for teaching those subjects is no longer adequate. The council have accordingly commenced to build more commodious laboratories and lecture rooms for teaching mechanical and electrical technology. These laboratories, when completed, will, says Prof. Fleming (writing to the *Daily News* of Wednesday), offer greatly increased facilities for teaching these applied sciences. The council do not at present see their way to incur the additional expenditure necessitated by these improvements. It is estimated that a sum of at least £2,000 will be required to fit up properly that part of the laboratories to be devoted to electric engineering, and subscriptions are invited from the friends and old students of University College, to be sent to the Secretary of University College, marked "Electrical Apparatus Fund."

The Conversazione.—The President of the Institution of Electrical Engineers (Prof. W. E. Ayrton, F.R.S.) and Mrs. Ayrton received a brilliant assembly to their *conversazione* on Friday last. From 9 o'clock till midnight the beautiful rooms of the Royal Institute of Painters in Water Colours were crowded, at one time almost inconveniently crowded, so great was the popularity amongst electrical and scientific celebrities of Prof. Ayrton's reception. Amongst the numerous assemblage of visitors and members present we may mention: Prof. W. Grylls Adams, F.R.S., Sir James Anderson, Sir Benjamin Baker, K.C.M.G., Mr. C. Vernon Boys, F.R.S., Mr. A. R. Bennett, Mr. R. E. Crompton, Prof. W. Crookes, F.R.S., Captain Creak, R.N., F.R.S., Prof. Crocker and Mr. W. J. Hammer, (both vice-presidents of American I.E.E.), Sir

H. Doulton, Mr. H. W. Christmas (Servian Consul-General), Prof. Carus Wilson, M.A., the Rev. J. R. Diggle, Prof. G. Forbes, F.R.S., Mr. S. Z. de Ferranti, Mr. Desmond FitzGerald, Mr. E. Graves, Sir Douglas Galton, K.C.B., Dr. E. Frankland, F.R.S., Prof. G. Carey Foster, F.R.S., Major-General Festing, F.R.S., Dr. J. H. Gladstone, F.R.S., Prof. D. E. Hughes, F.R.S., Colonel R. Raynsford Jackson, Dr. J. Hopkinson, F.R.S., Dr. E. Hopkinson, M.A., Lord Kelvin, P.R.S., Prof. Oliver Lodge, Mr. W. H. Preece, F.R.S., Sir Henry Mance, C.I.E., Prof. R. Meldola, F.R.S., Mr. E. Macrory, Q.C., Dr. Ludwig Mond, F.C.S., Dr. Hugo Miller, F.R.S., Mr. Gisbert Kapp, Major Flood Page, Prof. A. B. W. Kennedy, F.R.S., Prof. J. Perry, F.R.S., Mr. J. W. Swan, M.A., Sir D. Salomons, Bart., Mr. C. E. Spagnoletti, Mr. A. Stroh, Earl Russell, Prof. S. P. Thompson, F.R.S., Mr. Edward Woods, Mr. R. W. Wallace, Prof. W. Ramsay, F.R.S., Dr. John Rae, F.R.S., Mr. G. J. Symons, F.R.S., and many others. During the reception, while visitors were inspecting the lovely portraits on the walls, or exchanging greetings, the band of the Royal Horse Guards Blue were down to play a fine programme of music. A rather unique ending was given to this meeting by the energies of Mrs. Ayrton and her friends, who just before midnight arranged an impromptu carpet dance, bringing to a merry finish a most enjoyable social evening.

High-Tension Transformers. — Experiments in high-tension work have been carried out hitherto almost exclusively by German, English, and American engineers. France is now taking her part in this field of work, and a series of high-tension transformers have been recently constructed for MM. Hutin and Leblanc, to be used at the Société de la Transmission by M. Labour, engineer to the Société L'Eclairage Electrique. The experiments of MM. Hutin and Leblanc have necessitated the construction of transformers of special output. One of these is for a capacity of 6,000 watts, transforming from 150 up to 10,000 volts, with an efficiency of 94 per cent. at a frequency of 80; this transformer can be run up to 30,000 volts without difficulty. Two other transformers, of 15,000 watts capacity, transform from 25 volts up to 10,000 volts, with an efficiency of 88 per cent. at the minimum, at a frequency of nine, and by increasing the frequency the pressure can be run up without inconvenience to 36,000 volts. Special precautions have been taken to guard against faults. The primary and secondary circuits are entirely separated from each other, and immersed, for one of the transformers, in paraffin, and in the two others in oil arranged to circulate freely. It is interesting to note that the length of one of the primary circuits is 14 kilometres (about 8½ miles). These transformers are constructed for the system of double transformation, transforming both at the generator and at the receiver. This system is now acknowledged have considerable advantages over the direct method for high-tension work. The low-tension dynamos are less expensive, more efficient, and much easier to manage. The danger to the attendants is less, and the material used is cheaper. The efficiency of the transformers is taken in the following manner: The average output of the transformers was raised to 4,000 watts at 25,000 volts, and with a frequency of 43. Two transformers were coupled together for double transformation. The thick wire of the first was connected to a low-tension dynamo, and of the second to a set of variable resistances without self induction, and the two fine-wire circuits, at 25,000 volts, were connected together. The energy given at the terminals of the low-tension circuit of the first transformer and that received at the non-inductive resistances of the second was measured by ampere-meter and voltmeter. It was found that the efficiency of each transformer was 94 per cent. at half load. It must be noticed that this supposes the apparent self-induction of the transformers themselves to be nil, and the real efficiency is therefore rather higher than that found. These transformers are the first of their kind built in France, and the result of the experiments has given great satisfaction to the designers and manufacturers.

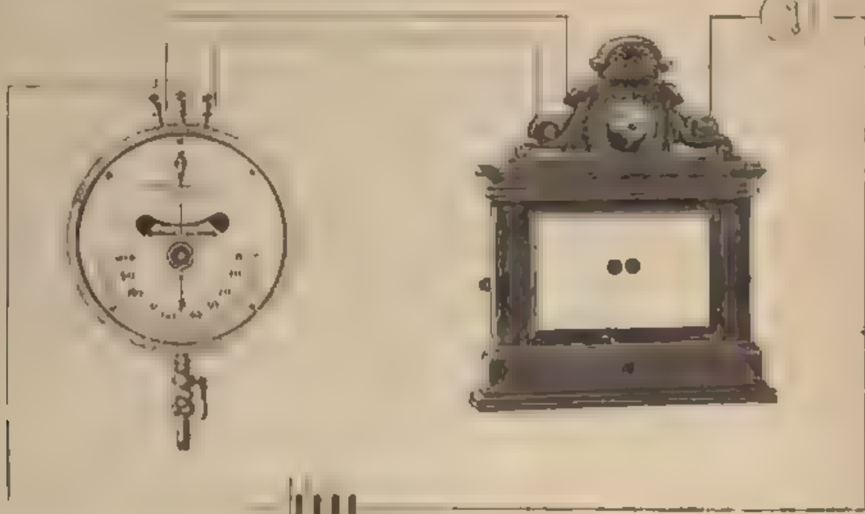
Bruce War Balloon.—An ascent of the Bruce electrical war balloon was made on Thursday night in the Stamford Bridge Grounds, Fulham-road, under the personal superintendence of the inventor, Mr. Eric Bruce, M.A., F.R.Met.S., to demonstrate the utility of the balloon for flashing signals by night. This method of signalling was first exhibited at the Inventions Exhibition of 18.5, and while on exhibition the system was referred for Government trial by the Royal Engineers at Chatham, and the result was that orders were shortly after received from the War Office. A second trial, undertaken in a snowstorm, was equally successful, and the Belgian and Roumanian Governments investigated the invention. The object of the invention, as its name implies, is to facilitate night signalling to long distances and in places where ordinary signalling would be impracticable, such as in wooded and hilly districts. With the help of a translucent balloon lighted interiorly, a mountain between two friendly parties would place no barrier to inter-communication. The apparatus is simple and portable, consisting of a balloon made of a material that is perfectly translucent, with several incandescent lamps, supported on a specially devised holder, placed inside. The lamps are connected with batteries on the ground. In the circuit is an apparatus for making or breaking contact rapidly, and by varying the duration of the flashes of light it is, of course, possible to signal according to the Morse or any other code. Various improvements in detail have been made, and the demonstration was to show the practicability of the invention for war purposes. The balloon used is 18ft. in diameter, made of extremely translucent material. Six 16-c.p. lamps are placed inside, taking a total of nine amperes at 24 volts. The battery used is 26 E.P.S. cells of E 7 type. The improvements mainly consist in the reduction of weight in almost every portion of the apparatus, so as to increase its portability and efficiency. The balloon itself is made of a much lighter material than those first exhibited, while the weight of the ladder-shaped holder inside the balloon is reduced to a minimum. Each of the storage cells now only weigh 24lb. An improved signalling key is used, having carbon contacts; these can easily be renewed at trifling cost when worn away by the sparking. The system of signalling by the translucent balloon is supplemented by an arrangement for flashing lamps outside the balloon, as this plan is thought to be better adapted for certain conditions of atmosphere, when penetration is desirable. It has, however, been found in practice that the system of flashing lights inside the balloon has, in clear weather, great advantage over outside open lights, as it produces flashes that are sharp and distinct, whereas signalling with open incandescent lamps is apt to produce indistinctness, owing to the fact that incandescent lamps do not cease to glow instantaneously when the current is interrupted. The balloon is also useful for navy and coastguard signalling. The experiments shown consisted of ascent of pilot balloons and of the large translucent balloon; exhibition of system of flashing signals by lamps inside balloon; continuous illumination of balloon for use as fixed point; moving the lighted balloon a short distance above the ground as a light for working parties; flashing of open lights outside balloon; finishing by flashing "God save the Queen" in Morse code.

THE CRYSTAL PALACE EXHIBITION.

Continuing the description given on June 24 of the exhibit of American electrical specialities by **Mr W. J Hammer,** we give some account of two important exhibits in the shape of the Ward arc lamp, and the automatic recording instruments of the Telemeter Company

Ward Arc Lamp. -The action of this lamp has been much admired at the Crystal Palace. It gives a remarkably steady light, and its action at cutting in seems simply perfect. The arc strikes at once without the slightest difficulty, and starts right off, without flickering or jumping, at full brilliancy. The Ward arc lamp is manufactured by the Electric Construction and Supply Company, of New York, and, we are given to understand, is taking, or has taken, precedence in America over almost every other form of arc lamp. To give some idea of the use of these arc lamps in New York and suburbs, it is sufficient to mention that the Edison Company of New York and the Edison Company of Brooklyn have each central stations of a capacity of 130,000 16 c p. lamps, and both of these stations have over 1,100 Ward arc lamps running on their incandescent circuits, and are increasing the number at the rate of 100 a month in each. The special type of lamp here alluded to is the continuous current lamp for running on incandescent lamp circuits—a type that is now most in demand. The Ward Company manufacture no less than 43 different types of arc lamps, both for series and parallel running, and for alternating and continuous currents, but the lamps shown at the Crystal Palace are of the type that is meeting with the most extensive sale—to run two in series on a 100 110 volt circuit. The lamp is very simple in construction, with gravity feed, and although great sensitiveness is claimed for its action, it will burn satisfactorily a cheaper kind of carbon than most lamps in the market. Experiments which we witnessed showed the lamp can be cut in and out any number of times in succession, the arc starting instantly, while not the slightest flicker in burning is perceptible.

The Telemeter Company, of New York, exhibit a set of their indicating and recording instruments, which are the result of 14 years' experiment in simplifying and perfecting electrical recording apparatus. Over £20,000 have been spent in perfecting these instruments, and many valuable ideas have been embodied covered by patents held by the Telemeter Company. The various instruments are shown at the Crystal Palace in practical operation, in recording the pressure of the boilers, temperature of the rooms, pressure on the water system, the electric mains, and so forth We see telebarometers, telethermometers, telemanometers, and other telemeter instruments for indicating and recording steam, water, gas, and other pressures, of levels of water, oils, or other liquids in reservoirs, standpipes, the movements of gasometers, temperatures of fluids, gases, etc., or vulcanising or welding furnaces, drying-rooms, and breweries. Many of these instruments are in use in America, employed by various prominent companies, municipal corporations, and others. Automatic recording and electrical instruments are shown at work on the same plan, for registering at a distance. These instruments are fitted with an adjustable alarm contact, for high and low points, to ring a bell at any desired place. The exhibit forms a very valuable collection of recording instruments, such as are likely to prove a great aid in many departments of business.



Telemeter Instrument for Indicating Pressure at a Distance.

Cables and Wires.

If one could only see and realise the fact, perhaps the most important and largest article in use at the Electrical Exhibition is not the machinery, the lamps, or the fittings, but the wire. In the shape of cable large and small, bare and covered; of copper conductors—strip and wire, of flexibles—telegraph, telephones, electric light, submarine cables, bells, heaters, and power transmission—all these require one important factor summed up in the word "conductors." The total length of wire used in the Crystal Palace Exhibition must figure as something almost appalling. Unfortunately, from the exhibitor's point of view, most of it is out of sight, silent, unmoving, unappealing to the general inquisitiveness. There is a strange fascination to the human mind in seeing anything in action, it appeals to the "time factor" of the brain, as one might say, and even those who are best instructed and know exactly what to go to and what to look for, are always arrested by a movement or an unusual noise in an exhibition. It is for this reason that moving machinery and processes in action always prove the most attractive part of exhibitions But the wire—the mere "electric piping," useful, though humble, servant of the dynamo and the lamp—how can this be expected to catch the attention of any but the specialist? Nevertheless, the great firms—Henley's, Glover's, Silvertown, Siemens, Johnson and Phillips, Helsby—all wish their names brought prominently before the world in connection therewith, for who knows in this age of electricity what orders for thousands of pounds worth of goods may not be going at any moment.

The question might indeed very well be asked, Which is the best way to exhibit cables and wires? Sections of cables and coils of wire are very good in their way, especially if made up into handsome trophies. But could we not see sets of samples in process of manufacture, from the commencement, action by action, layer by layer, to the finish? Then, again, conductors are made to conduct, to carry electrical energy. Could we not see them as conductors, endowed with strange properties, instead of inert masses of rubber and copper? It might be an idea worth having. Wires with waxing and waning currents passing would be easy to arrange, and the effects on magnetic needles or by electromagnets would be noticeable, large solenoids, with suspended floating iron cores and other devices, might, indeed, savour of lecture tricks, but would

certainly prove interesting to any visitor; while an organised set of scientific experiments and tests, on insulation resistance, electrostatic capacity, sparking distances for high voltage, specification of tests to be stood by electric light cables, and so forth, should give, by the emulation of the manufacturers, valuable results to the scientific and practical world.

But we must put aside such matters for the present. The Crystal Palace Electrical Exhibition of 1892 has come and gone, leaving many problems raised and discussed, and a better knowledge given to the public of the immense strides of progress made since 1881. If in any particular branch there is not so much progress necessary, it is in the manufacture of electric cables, which already by the needs of telegraphic work in early years had then reached a very high point of perfection. The adaptation of telegraphic cables to electric light requirements was effected without much difficulty. The adaptation of insulated cables to withstand the enormous electrical pressures of 2,000, 10,000, or even 50,000 volts, was far more difficult, but it has been done, and the future may see these latter degrees of pressure no more thought of than 150lb. or 200lb. pressure of steam is now. For this we have to thank both the progressive nature of a few enthusiastic electrical engineers, and the able work done by the manufacturers, who, ever ready to adapt themselves to the growing needs of the industry, have spared no pains to fulfil the demands upon their skill.

Among the foremost of the great cable and wire manufacturers we have to mention **W. T. Henley's Telegraph Works Company, Limited,** of Martin's-lane, Cannon-street, and North Woolwich. This company have been widely occupied in cable manufacture ever since the foundation of the works by Mr. Henley in 1853, since which time over 15,000 miles of submarine cable have been made by them. At the time of the great development of the electric light industry in 1881, they introduced the patent ozokerited indiarubber cores and the vulcanised rubber insulation, and from that period onward have followed the increasing activity in telephone, electric light, and transmission work, producing all kinds of insulated wire and cable, up to the most recent requirements, among which we should mention the underground electric light cables for the Glasgow Corporation. These cables are of very large size, the case being half square inch section; the weight of the conductor is five tons to the mile, and the insulation 1¾ tons—being a total weight of 6¾ tons to the mile. The exhibit of the Henley's Company at the Crystal Palace contains some large plates of electrolytic copper of a minimum conductivity of 100 per cent. of Matthiesen's standard, being samples of the copper used in the electric wires and cables produced by the company. We see samples of the raw Para rubber as imported, many of the pieces being sent in amusingly grotesque shapes, as of ducks, bags, and various ornaments; then the pure rubber sheets and strips for insulating, and braided and hemp-covered cables. Sections of their submarine cables are shown, both deep-sea and shore-end; we see electric light cables for high and low tension work, arc and incandescent; telephone cables with separately insulated wires, and a large variety of smaller wires for different purposes. Round the stand are some extremely interesting photographs showing their cable ship "Westmeath"—being loaded with cable on its way abroad, during the process of laying and testing, with views of the machinery for paying out and buoying; and also some of the telegraph huts and shore ends for the submarine cables laid by the Henley Company. We also notice a case of the "Block" dry cell; a solid dry cell arranged in strong oaken case for hard work, forming a solid block. Their exhibit, though not large, is most important and suggestive, and the references to the large amount of work carried out in all parts of the world fully illustrates the position of the company in cable manufacture.

Another very noticeable exhibit of electric wires and cables is that of the well-known firm of **Walter T. Glover and Co.,** of 39, Victoria-street, Westminster, and Salford, Manchester. They have a very handsome exhibit, comprising practically every variety of electric light and telephone cable and wire that is in use at the present time. Cables for electric light and power naturally occupy the chief place, and the various qualities of insulation are represented by coils and sections. A specially fine show is made of flexible wires for indoor use—for telephones, pendants, movable electric standards, connection of instruments and dynamos, flexible cables, and so forth. Another speciality is the patent flexible metallic tubing applied to electric wires and cables. This flexible tubing consists of overlapping steel corrugated rings, tightly fitted in such a way as to afford perfect protection from ordinary injury and yet to be quite as flexible as ordinary stranded cable. A fine show is made with anti-induction telephone wire cables, to which special attention has long been paid by Messrs. Glover, and cables wrapped with foil round each wire to prevent induction are shown in different varieties. An exhibit is made of the hard drawn copper produced by Messrs. F. Smith and Co., of Halifax, used by Glovers for the cores of their cables and wires; and an interesting set of samples of wire gauge for different purposes is also shown. An exhibit of special interest to dynamo makers is the Compactum insulated copper strip or wire, very firmly and thinly, but well, insulated with varnished serving, ready wound on 2cwt. and 4cwt. drums for use in winding armatures. The amount of patient ingenuity and skill in adaptation of material to requirements needed for all the varieties of insulated conductors shown on their stand can hardly be indicated to the general public by the various sections and samples, but the technical man will have inspected them with great interest and appreciation.

Behind Messrs. Glover's stand we see a full-sized set of the **Johnstone Electric Subway Company's** patent conduits. We have already given, in our articles upon underground mains, full particulars, with illustrations, of this interesting system, of which it is proper to say it provides in a simple and easy manner for laying electric wires of all kinds in cast-iron troughs, and allows for connection and inspection with the least derangement of the conduit. Some hundreds of miles of conductors have been laid on this system in New York and other American towns, and its introduction is under contemplation in certain towns in England.

JURORS AND AWARDS.

The following is a list of the jurors and the awards made:

JURORS.

Prof. W. Grylls Adams, D.Sc., F.R.S.
Mr. L. Atkinson.
Prof. W. E. Ayrton, F.R.S.
Mr. Shelford Bidwell, M.A., F.R.S.
Mr. Conrad W. Cooke, M.I.E.E.
Prof. W. Crookes, F.R.S.
Mr. W. B. Esson, M.I.E.E.
Prof. George Forbes, M.A., F.R.S.
Major-General Festing, R.E., F.R.S.
Capt. Sir Douglas Galton, K.C.B., F.R.S.
Dr. J. H. Gladstone, F.R.S.
Mr. J. H. Greathead, M.I.C.E.,
Mr. Chas. Hall, M.I.E.E.
Prof. D. E. Hughes, F.R.S.
Sir Hy. C. Mance, C.I.E.
Mr. W. H. Massey, M.I.C.E.
Prof. J. Perry, F.R.S.
Mr. W. H. Preece, F.R.S.
Mr. A. Rechenzaun
Prof. Hy. Robinson, M.I.C.E.
Capt. Sankey, R.E., M.I.E.E.
Mr. C. E. P. Spagnoletti, M.I.C.E.
Mr. Albion T. Snell.
Mr. W. E. Sumpner, D.Sc.
Mr. James Swinburne, M.I.E.E.
Prof. Silvanus Thompson, D.Sc., F.R.S.
Mr. J. Tomlinson, M.I.C.E.
Prof. W. C. Unwin, B.Sc., M.I.C.E.
Major-General Webber, C.B., R.E.
Mr. J. W. Wilson, M.I.C.E.

AWARDS.

Diploma of Honour.

THE "DAILY CHRONICLE" INSTALLATION.

We have assisted at a good many ceremonies and inaugurations in our time, but seldom, perhaps, never before have we had experience of such a unique and brilliant inaugural ceremony as that which was held late at night, or rather early in the morning, a week ago at the *Daily Chronicle* offices in Whitefriars-street. In the first place, the hour of the invitation—"midnight to 4 a.m."—is rather uncanny to anyone but a "high society" personage, an actor, or a newspaper man (and of all three there were abundance, too, crowding at this function) and the general interest of the exhibition—for it was one of the mighty machinery turning out newspapers by the thousands and tens of thousands at the rate of 20,000 each an hour, beside the special interest of the complete installation of electric light in every corner—all this, commingled with the brilliant scene of moving figures and familiar distinguished faces, made a scene it is not easy to forget, and one which our readers may perhaps like to partake of in fancy in print for a few moments. We will first give a general idea of the scope of the businesses here involved before describing the function we were to witness. These consist of the printing and publishing of *Lloyd's News* and the *Daily Chronicle*, together with the paper making business at Sittingbourne, the whole comprised under the title, Edward Lloyd, Limited. No weekly newspaper, perhaps, is better known or more widely read than *Lloyd's Weekly Newspaper*, a journal that has a circulation of over three quarters of a million a week, and is still growing. It is known in all parts of the civilised and uncivilised world, and is a sort of recognised medium of intercourse throughout Imperial Britain, between home and the colonies. This paper is printed on Hoe rotary printing machines on the same premises as those of the *Daily Chronicle*. This latter newspaper, one which is rapidly taking an advanced place amongst the large dailies of London, has a daily circulation of over 100,000, and is, we must acknowledge, one of the brightest and most interesting of the morning papers. The actual paper, required by tons and tons at a time, for these journals is made by Messrs. Lloyd at their paper mills at Sittingbourne, which have also been fitted up with electric light.

As it is not often, perhaps, that our readers have the opportunity of assisting at the production of the paper which they buy so easily for a penny at the stalls in the morning, as they have never gone through the process so beautifully timed and organised, with their nerves of telegraph wires stretching to the farthermost corners of the earth, constantly feeding the printing machines—they may like, before attending to the electric light, to look on, as did the visitors, at the whole process from start to finish.

Receiving the visitors at midnight in a large storeroom, fitted for the nonce with red carpet and bunting, and daintily decorated with palm leaves and flowers, is Mr. Frank Lloyd, the present head of this great business. We notice M.P.'s, authors, leading civil and business men, dramatists, artists, and editors. Among them are to be noted Mr. Dibbs (fresh from Australia), Sir A. Rollitt, Mr Causton, M.P., Sir J. Crichton Browne, Colonel Hugh Douglas, Mr Yates Thompson, Dr. Lennox Browne, Mr. Syme (editor of the *Melbourne Age*), Mr. Toole, Sir Augustus Harris, Sir Somers Vine, Colonel Byng, Mr. F. C. Gould, and Sir Frederick Abel. All Fleet-street, broadly speaking, was present—a veritable institute of journalists; and the black-coated crowd wandering at dead of night amongst the rattle of machinery and the glare of the composing room, made a curious contrast.

That quiet young man in short brown coat, chatting unconcernedly to the visitors, is Mr. Massingham, one of the best known and most influential of London journalists. We will follow him, if you please, as he slips away for a moment upstairs, about half-past one, into the quiet sanctum. A telegraph form is rapidly perused, a note rapidly penned, a proof glanced through, and a few corrections made, and the editor's work is finished for the night. We go up to the composing-room; we see the eager army of shirt-sleeved men, bending this way and that over their cases of type—the message flies into lead type, line by line, and half-a-dozen men clap their "takes" together; it is pulled in proof, read, corrected, and dropped into place in a huge iron frame, where columns more are ready for this last word, and before one can realise it, the type is knocked level, screwed up, and is sinking down the lift to the foundry. Here, indeed, is a busy, and withal a hot, scene. All are waiting like acrobats for the performance. The ovens glow with heat, the lead is melted and quivering in the foundry. The men seize the flat "forme" of set up lead type, clean it vigorously; then a thick sheet of papier mache is thrown on top, and whack, whack, a stiff brush struck all over it, makes the impress of the face of the type on the soft thick paper sheet. It is rolled, a sheet of brown paper is rapidly pasted at back; the matrix thus formed is torn off and dashed into an oven to dry. The leadfounder stirs up his melted metal and the men range themselves in file for the last effort. Out comes the paper matrix and is rapidly adjusted in a semicircular iron case: the press comes down upon it, the back of the hollow casting-box is brought sharply down upon this and screwed up with a jerk, and the whole is stood on end to receive the lead. Two swarthy founders rush up with their double-handed pot of lead, and in it goes; a jerk to settle it, a blast of cold air, and the case is opened and the semicircular stereotype is lifted out, the matrix detached to serve for another and yet two or more other stereos. The stereo itself is cut off to shape with lightning speed, its edges and inside trimmed, bits are cut out by men whose chisels seem to fly dangerously near each other's eyes. In a minute or two, certainly under five minutes of the start, the stereo is sent down by lift to the printing-room.

We run down just in time to see the last act. The huge printing machine is surrounded by attendants and as

expectant crowd. The long wide strip of paper is already adjusted through the straps and rolls, the engineer standing with his hand on the lever. The stereo is lifted, shot into place on the roll, screwed up—and the press is ready. The lever is turned and the machine begines slowly, slowly at first, rapidly increasing in speed till a deadly rattle and screech in the air prevents even shouting from being heard. The huge roll of paper at the back spins round, rushes in a grey streak up, down, and through the rolls; and at the other side, upon a revolving receiving band, come rushing out almost like grain from a sack, sheaves and sheaves of *Daily Chronicles*, printed, extra sheet inserted and gummed, and all folded ready for sale. They come tumbling out, amidst the incessant din, in heaps and heaps, ready counted into quires of 26—the salesman's two dozen—and the busy hands lift them off, stack them, tie them up, and take them into the publishing-room, where W. H. Smith and Son's waggon is waiting for the delivery. With freshly-printed copies in hand, the visitors emerge from the brilliantly lighted, screeching machine-room into the fresh air, where the cold grey of morning already gives a ghostly clearness to the deserted streets. Such is the process of production of a daily paper; and of all the printing establishments with which Fleet-street abounds, that of Messrs. Lloyd now stands very nearly, if not quite at the head.

The Electric Light Installation.

The premises of Messrs. Edward Lloyd, Limited, are very scattered, being situated partly in each of the following streets: The advertising office for the *Chronicle* is at 80, 80A, and 81, Fleet-street, this being quite separated from the other portions of the buildings, and is the most distant point from the dynamos. As to the main portion of the building, it extends from Salisbury-square on the east to Whitefriars-street on the west, and for a small portion at No. 72 it fronts Fleet-street on the north, the basement being excavated under the intervening courts—viz., Angle-court and Hanging Sword-alley.

The electric light engine-room is situated in the basement of the building fronting Whitefriars-street, being part of the *Daily Chronicle* machine room, from which it is partitioned off with a brick and glass partition. The size of the engine-room is 21ft. by 10ft. wide.

The boiler used at present is the same used for the engines which drive the printing machines, one of the two being generally found sufficient for the whole of the work, except on Friday nights, when *Lloyd's Weekly News* and the *Daily Chronicle* are both being printed, and the two sets of engines and boilers have then to be used. They work at 60lb. steam pressure.

The power is supplied by two Invincible engines, made by Messrs. John and Henry Gwynne, of the Hammersmith Iron Works. They have cylinders 13½in. diameter by 10in. stroke, and run at 300 revolutions per minute. The engines exhaust into the general superheater; they are fitted with special lubricating arrangements for continuous running.

The current for lighting these extensive premises is generated by two four-pole compound Phœnix dynamos, built by Messrs. Paterson and Cooper. These machines are mounted on the same bed-plate as the engines, and the armature shaft is coupled direct to the crankshaft of the engine. The whole arrangement forms one of the most compact plants of the size in existence, measuring only 6ft. 4in. over all in length, and the broadest part of the arrangement—viz., the magnet ring—being only 4ft. 10in., and the total height of the engine being 9ft. 2in. The four magnet coils are mounted on a cast-iron hexagonal ring; they are wound on brass bobbins which are slipped over the pole-pieces, these latter being bolted to the ring. The armature is of the Gramme ring type. The output of each machine is 240 amperes at 105 volts when running at 300 revolutions per minute. The eight brushes are mounted in pairs on spindles attached to a circular rocker, enabling both pairs to be adjusted at the same time. The brushes are made of copper gauze, and the dynamos run without the least spark.

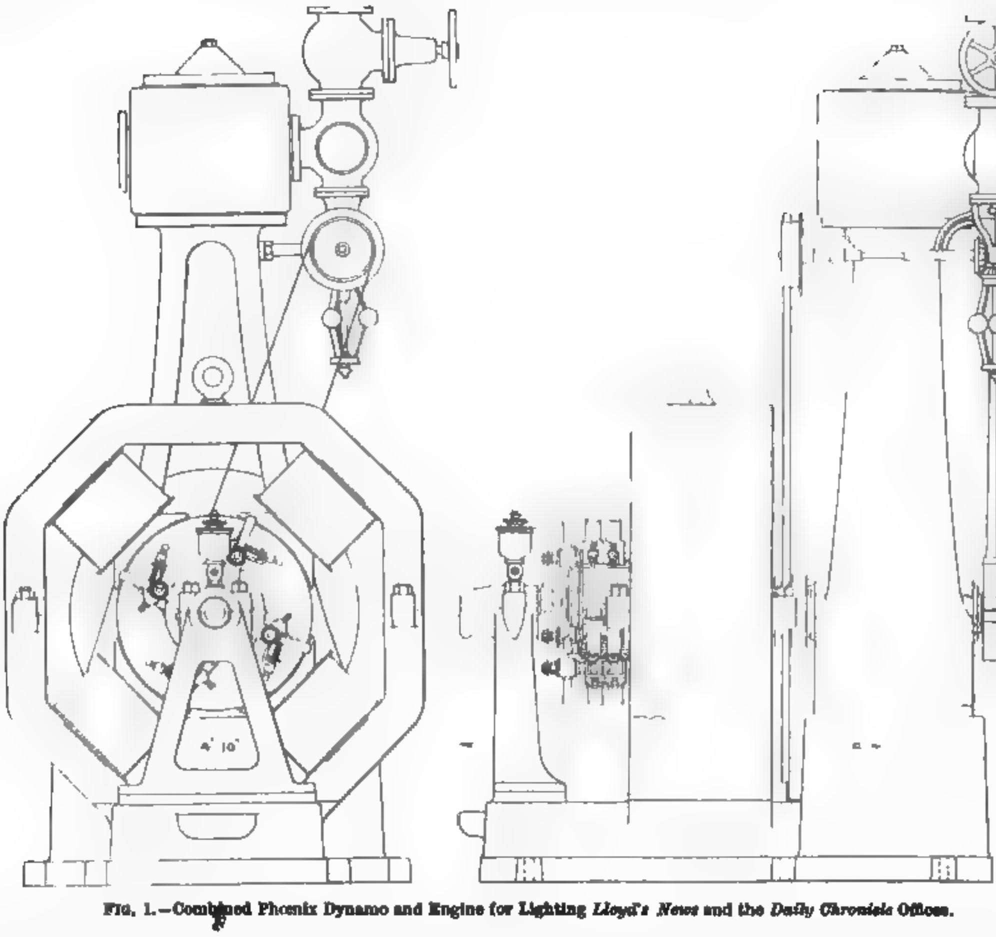

Fig. 1.—Combined Phœnix Dynamo and Engine for Lighting *Lloyd's News* and the *Daily Chronicle* Offices.

The arrangement of the plant is shown in the drawing, Fig. 1, the two engines, which are right and left handed, being placed together in the centre of the room and the two dynamos towards the outside; the switchboard is placed at one end.

The switchboard consists of an enamelled slate tablet 6ft. long by 2ft. 6in. high, mounted in a polished teak frame. This board carries the eight circuit switches for controlling the lights, with double-pole fuses to each circuit, and also

the double-pole switches and fuses for the dynamos and the instruments. The distributing switches consist of two-way spring lever switches by means of which any circuit can be switched from one machine to the other with hardly a perceptible flicker in the light; over each of these switches is placed a pilot light run from the particular circuit which it controls, so that the engineer-in charge can see exactly what circuits are on, and if they all right at a glance. Each dynamo is provided with a double-pole switch, double-pole fuses, and an ammeter. One voltmeter is fixed with a two-way switch, so as to enable the readings to be taken from either machines.

The instruments are of the Phœnix dead beat electro-magnetic type, they have 6in. dials and are direct reading respectively to 250 amperes, and the voltmeter to 110 volts.

The mains from the dynamos are carried underground, and at the back of the board is a space of 2½ft., so that the connections can be easily got at if necessary. The connections at the back of the board are made by means of copper strips.

The current is divided over the eight circuits as follows: (1) *Chronicle* composing-room; (2) *Chronicle* offices; (3) *Lloyd's* offices, (4) *Lloyd's* machine-room; (5) export and stationery department; (6) Fleet-street advertising offices; (7) *Chronicle* machine and engine rooms, (8) *Lloyd's* composing-rooms.

The "Chronicle" Composing-room is situated on the top (third) floor of the building in Whitefriars street, in the basement of which is the engine-room. The mains run from the switchboard up an air shaft into the centre of the room, where they divide into four branch circuits, each protected by two single-pole fuses; these circuits run right and left along the sides of the room, from which five-light branches are taken, each again protected by two single-pole fuses. The fittings over each composing frame consist of porcelain ceiling rose, with fuse, glazed cotton cord, with Edison Swan bayonet joint key socket-holders, and a specially made enamelled iron shade, constructed so as to throw the whole of the light into the frames, and to keep it off the eyes of the compositors. The total number of lamps on this circuit is 167 16-c.p. lamps.

The "Chronicle" Offices comprise the ground, first, and second floors of the Whitefriars-street building, including the editorial department, writers' and reporters' rooms, stereo-room, paper reel-room, and publishing offices, and also five 50-c.p. lamps in the street, four of them being fixed in "bulkhead" fittings against the wall, and the other, 50-c.p. lamp, being fixed in the lantern over the door. The total of lamps in the *Chronicle* offices amounts to:

16-c.p. lamps	139
32-c.p. lamps	3
50-c.p. lamps	5

The fittings in the above department consist chiefly of pendants, those in the writers', reporters', reelroom, and lavatories, publishing offices, and passages have opal shades; the editorial staircase gilt three-light ceiling fittings with opalescent frill shades; while the passages have large iced shades. The editors' rooms and offices have centre three-light electroliers and pendants round the sides and over the desks, with one or two table standards in each room. The ceilings being all iron and concrete, and newly decorated with ornamental cornices, rather a novel arrangement of wiring was introduced: the casing was run round the rooms under the cornice, and ceiling roses were fixed on it, from which flexible cords were carried through counterweights over pulleys fixed where the lights were required, as shown in the sketch, Fig. 2.

"Lloyd's" Office.—The circuit for *Lloyd's* office includes the whole of the buildings in Salisbury-square excepting the basement. In the private offices, etc., three-light brass ornamental electroliers are fixed, and in the other parts of the building plain opal shade pendants are used. The mains from the switchboard run up the air shaft and across Hanging Sword alley in a special covered-in box on insulators, with several other circuits. There are 80 16-c.p. lamps on this circuit, besides a 100-c.p. and a 200-c.p. lamp in Angle court. The 100-c.p. lamp is fixed in the lantern at the entrance of the court, and the 200-c.p. lamp is fitted in an enamelled iron shade, and suspended in the centre of the court.

"Lloyd's" Machine-room.—This circuit includes the whole of the various basements to the east of Hanging Sword-alley—viz., the basements of 12 and 13, Salisbury square, and of from 2 to 13, Crown-court, including the excavated portion under the court itself. The fittings on this circuit are mostly either white opal or enamelled iron shade pendants, with the exception of those lamps fixed on the machines themselves. These latter lights constitute one of the chief features in connection with the installation. A difficulty was at first experienced on account of the very rapid vibrations of the machines, which rendered the ordinary bayonet

Fig. 2.—Counterweight Pendant at the *Daily Chronicle*.

joint lampholders useless, as the lamps are found to break off at the collar after a few hours' run. This was got over by a special form of holder, as shown in the sketch, Fig. 3, the object being to support the lamp from the bulb itself, and quite apart from the connections, and to attach the lamp to the circuit by means of a flexible cord. Referring to the sketch, it will be noticed that the light frame composed of No. 10 B.W.G. brass wire is screwed to the frame of the machine at A A; to insert the lamp, the supporting ring, B B, is pressed back against the springs, S S, and the point of the lamp inserted in the hole, C, the ring, B B, being then allowed to come over the neck of the lamp. We might mention that loop lamps were tried, but they were found to burn through at the loops on account of the vibrations causing sparking at the contact

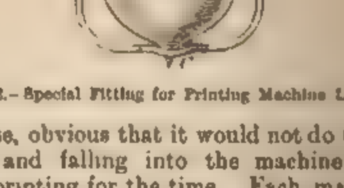

Fig. 3.—Special Fitting for Printing Machine Lamps.

It is, of course, obvious that it would not do to risk a lamp breaking off and falling into the machine and perhaps stopping the printing for the time. Each machine is fitted with eight lamps as described above, besides having eight opal shade pendants over it and a portable lamp and plug connection for the purpose of getting to the shafting, etc., underground; the two switches, one for the machine and one for the pendants, and the plug are in most cases fitted into a box and let flush into the wall, so as to be safe from breakage. There are 110 16-c.p. lamps fitted on this circuit in all, including those fixed in the new engine-room. The mains from the switchboard run through the *Daily Chronicle* machine-room and along the passage under Hanging Sword-alley into *Lloyd's* machine room.

Export and Stationery Department.—This circuit comprises the ground, first, second, third, fourth, and fifth floors of

72, Fleet-street; the first, second, third, and part of the ground floor of the block on the eastern side of Crown-court, and on the western side the export stores and offices on the first and second floors. These lights have mostly enamelled iron or opal shade pendants, with adjustable counterweight pendants in the offices, and in the private offices portable table lamps are fitted. The mains run into the main building from the two sides of Crown court, and then through the passage under Hanging Sword alley to the switchboard. The total number of lights on this circuit is 96 16-c.p. lamps.

Fleet-street Advertising Offices, 80, 80A, and 81, Fleet street, are included in this circuit, this portion of the premises being quite separated from the rest of the works. This necessitated the employment of overhead mains; they run from the switchboard, up the shaft, and over the roofs for a distance of about 200 yards, and then drop down into the offices at the back. These mains run direct to an eight-circuit distributing-board, consisting of an enamelled slate tablet mounted in a polished teak case with glass front, containing eight switches and double-pole fuses; the main office is divided into seven circuits, and the eighth is used for the clock. There are 25 16 c.p. lamps over the desks in the main office, consisting of pendants with ground-glass frills over the counters and centre desks, and jointed brackets on the wall for the side desks; in the basement there are eight 16 c.p lights, the fittings being opal shades. In the windows there are 20 32 c p. lamps, plain pendants with ground frill shades, and in the face of the clock, looking up Fleet street, there are six 32 c p lamps. The advantage of having the electric light here has been already found out, as with gas, in the old *regime*, the face required cleaning at least once or twice a week, while now it will go on for months without attention.

The "Chronicle" Machine room.—This circuit comprises the whole of the Whitefriars-street building, including the electric light engine-room, main engine room, and boiler-room. The fittings are the same as described for *Lloyd's* machine-room. The total number of lamps fixed here is 112 16-c.p. lamps.

"Lloyd's" Composing-room, etc.—In this circuit is included the composing-room proper and the editorial offices. The fittings in the composing-room are the same as are used in the *Chronicle* composing-room, and those in the editorial offices consist of three-light electroliers in the centre, with portable table lamps and plain opal shade pendants in the passages, etc. There are 105 16 c.p. lamps on this circuit.

Both engines and dynamos are always kept ready for running, although it is only found necessary to run one all the week except during the heavy work on Friday night, when the second machine is started and some of the circuits are switched on it. One engine and dynamo is kept always running night and day.

The total number of lamps in the whole installation at Messrs. Lloyd's is 848 16-c.p, 23 32-c.p., five 50-c p., one 100, and one of 200 c.p. The work of superintendence and of designing and carrying out the details of this interesting installation has been in the hands of Mr. E. George Tidd, superintending engineer to Messrs. Paterson and Cooper, and the firm deserve the very greatest credit for the admirable way in which it has been carried out.

LARNE CENTRAL STATION.

Before these lines are read this station will be running. As our readers are aware, the work was undertaken and has been carried out by Messrs. J. E. H. Gordon and Co.

The buildings, which are quite an addition to the architecture of the town, are substantially built with good hard black stone of the neighbourhood and slated with native slates. The dressings of the doors and windows are of red brick, and give a very neat appearance to the buildings, which consist of an engine-house 44ft. by 30ft. by 15ft., a boiler-house 36ft. by 30ft. by 15ft., and a coal-shed to contain 30 tons of coal. The chimney, which is square, is 4ft. 6in inside, and is 60ft. high. Round the engine-room is a stained and varnished match-boarded dado, 4ft. high, finished with bold capping. The walls above that height are cement finished, giving a handsome and effective finish to the room. The whole of the buildings, boiler settings, and concrete engine beds have been carried out by Mr. A. Bremner, the contractors' architect. The following describes the equipment of the station:

The boiler-house contains two Cornish boilers by Messrs. Penman and Co., of Glasgow. The working pressure is 80lb. per square inch. The plates are of the best mild steel, the diameter of shell is 5ft. 6in. The total length of boiler is 20ft.; the shell plates are ⅜in. thick, and are in one plate in circumference, thus removing the longitudinal seams from the brickwork, as well as placing them out of the water space; the end plates are ½in. thick. There are three Galloway tubes in each boiler.

The engines, which are made by Messrs. Combe, Barbour, and Combe, Limited, Belfast, are of the single cylinder condensing type. The cylinders are 13in. diameter by 24in. stroke, and are fitted with Corliss valves. The steam-valves are fitted with a simple and efficient trip gear of Messrs. Combe, Barbour, and Combe's own design. This trip gear is very easy of control, and entirely under the command of the engine driver, who can disconnect it at a moment's notice. It is regulated by means of a high speed governor, which is fitted with a knock-off gear, by means of which the supply of steam is entirely cut off from the cylinder, in case the speed increases or decreases beyond certain limits. The air pumps are vertical, of short stroke, and actuated from the cross-head centre by means of links and rocking levers. The frames are of strong box girder section, with target ends, against which the cylinders are bolted, thus leaving them free to expand and contract in the direction of their length. The cranks and shafts are turned out of solid steel forgings, and the crank-pin, crank-shaft, slides, and other bearings are all made abnormally large, not so much for strength as to allow large wearing surfaces, to reduce wear and tear to a minimum, and to prevent heating up. The flywheels are 12ft. in diameter, with eight grooves for ⅞in. ropes, and will run at 85 revolutions per minute, and their weight is three tons. Cotton ropes are used for driving. The polished parts of the engine, with the exception of the crank-shaft, are all electro-nickel plated to prevent rust, and the whole of the engines are of neat design and well finished.

The alternators are two Mordey-Victoria machines of 25 kilowatts, running at 900 revolutions per minute; each alternator is excited independently by means of an exciter attached to the end of the alternator shaft. The E.M.F. is 2,000 volts.

The switchboard is of wood, is well made, and is 11ft. long and 3ft. 6in. high. The switches, fuses, etc., are all mounted on their own incombustible bases, and the volt and ampere-meters are on bases of their own, standing above the top of the switchboard.

The current is distributed by two pairs of high tension mains, $^7/_{16}$ cable in lead, made by the Fowler-Waring Cable Company, one circuit is 1,700 yards long, and has five transformers, three of 4 e.h.p. and two of 2 e.h.p, fixed on poles at various distances along the circuit—the three 4 h.p. feeding one pair of low-tension mains all in parallel, the two 2 h.p. each feeding their own mains, low tension, which is 100 volts. The other pair of mains, high tension, go from the station direct to a distributing centre 700 yards away, and feed at present four 4-h.p. transformers, but there are an extra pair of cables provided on this circuit, and the distributing centre is built to contain 12 4-e.h.p. transformers; the four 4-h.p. transformers here feed into a low-tension network which is well provided with double-pole copper fuses. These fuses are placed in convenient places for repairs.

The transformers used are of two sizes, 4 e.h.p. and 2 e.h.p., of the Mordey-Victoria type, and will work the three-wire system, 50 or 100 volts.

The whole of the buildings have been built with the intention of putting down another alternator and engine.

The town is at present lighted with 11 arcs (Brockie-Pell), which are very steady, and 50 incandescents.

The whole of the plant (including engines, boilers, and alternators) have been erected under the superintendence of Mr. W. M. Furniss, the company's resident engineer.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

CYRUS FIELD.

The news from America as to the health of Cyrus Field induces us to call attention to this remarkable man. He is, perhaps, the only representative of those pioneers of ocean cable finance who can claim the sympathy of two worlds. His early surroundings cannot enable us to say that he was cradled in the lap of luxury, and in his latest days he has lost his fortune through the speculative dealings of his son. During the years of his early and mature manhood Mr. Cyrus Field looms before us as a giant in initiating enterprise, in stemming disaster, and in bringing the enterprise to a successful issue. To Cyrus Field, more than to any man living or dead, Atlantic telegraphy owes its success. He preached submarine telegraphy much as Booth preaches the welfare of the residuum. He convinced friends and enemies as to the possibilities of the venture, and he obtained support where others said "impossible." A more consummate master in the art of plodding onwards through evil and through good report cannot be named. He had his reward in the success of Atlantic telegraphy, in the possession of a large fortune, in the honour and respect of those from whom honour is valued. That his fortune is gone is due to no fault of his—in fact, it adds to a due appreciation of the man for the loss is due to his love for, and his trust in, his son. In these days of hurly-burly strife—for lighting and traction—in the days of high volts and many amperes, submarine telegraphy as it appeared in the days prior to the Russian War can hardly be understood. With us it is a thing of little account, then it was a plunge into the vast unknown. Cyrus Field was the leader who led into the unknown, and who, like Columbus, had an overpowering personality. His followers might fret, might fume, might want to turn back from fright, but the goal was in the unknown, and into the unknown they had to go. Such are the men who make history. They require to be convinced, but once convinced there is no looking backwards, but a persistent forging ahead till the enterprise is won. From 1854 to 1866 Mr. Cyrus Field laboured to obtain Atlantic telegraphy. The cable in the latter year proved the link that has not since been severed. He had during these years to witness failure after failure. In 1857 the first attempt to lay a cable across the Atlantic was made. The attempt failed. With the knowledge of to-day, the wonder is that the attempt was made. It could end in nothing but failure, but, then, as now failure really spelled success. One by one the weak points were discovered, one by one they were remedied, till in 1866, as we say, a cable was satisfactorily laid across, and a cable that had been lost in the previous year was picked up, spliced, and completed.

Writing of the 1865 disaster Cyrus Field says "For twelve hundred miles she (the "Great Eastern") rode the sea in triumph, till in a sudden lurch of the ship the cable snapped, and once more all our hopes were

In the deep bosom of the ocean buried."

Fresh capital to the extent of six hundred thousand pounds was to be obtained, of which five hundred

thousand pounds, the cost price, was the sum the T. C. and M. Company required to manufacture and lay another cable. Besides this the contractors were, if successful, to have in shares and cash a profit at the rate of 20 per cent. upon such cost. Although efforts will be made to guide the praise into other directions, there is no doubt but that the whole merit of persistency was due to the indomitable will and energy of Cyrus Field. After this, the last of the failures, he urged, as he urged in 1857, the continuation of the effort, and he again succeeded in gaining his way. As we have said, the year 1866 saw the consummation of his labours. Atlantic telegraphy was indeed accomplished, and in less than a quarter of a century ceased to be regarded as anything extraordinary. The world can cheer the last days of the pioneer by granting that meed of honour and respect due to one whose work has changed the course of business in modern times. In his declining years, in the hours of his despondency, he needs the expression of sympathy from those who recognise the value of his labours :

Then, to this day, be honours paid
  The world's proud conquerors never knew ;
Their laurels shrink, their glories fade,
  Exposed to reason's sober view.
But reason, justice, truth rejoice
  When discord's baneful triumphs cease,
And hail with one united voice,
  The friend of man, the friend of peace.

ELECTROLYTIC CHEMICALS.

Electricity has already invaded to some extent the domains of commercial chemistry, but nothing approaching the amount it is likely to accomplish very shortly, if we are to believe the signs of the times. In electric smelting, and the production of pure copper and of aluminium and of zinc, we have had important application, though this is perhaps rather metallurgy than chemistry. Electricity is affecting chemical works in two directions—in the employment of electrical appliances in the factories, an instance of which we gave lately in the production by Armstrong's Glass Company, at West Bromwich, of large welded glass vessels primarily designed for accumulator cells. Electric light and electric motors have penetrated thereto as to other industries. But we speak now of actual chemical processes, of which, perhaps, the bleach and alkali production are of the most important. In these two branches alone there are invested for chemical manufacture in England not less than twenty-two million pounds sterling of capital, and this enormous industry is quite open to be entirely revolutionised at any time—and possibly not far distant—by the introduction of economical electrolytic processes of production. The subject is a fascinating one to dwell upon, but we must content ourselves for the present in pointing out the vast scope of the field for electrical application which lies before the electro-chemist, ready and waiting for harvest. These industries are presided over by keen business men, fully alive to the necessities for progress in improved and cheaper methods of production. By uniting the energies of chemists and engineers, a wonderful saving in first cost is a result to be safely expected, to the great increase of business and profits for both.

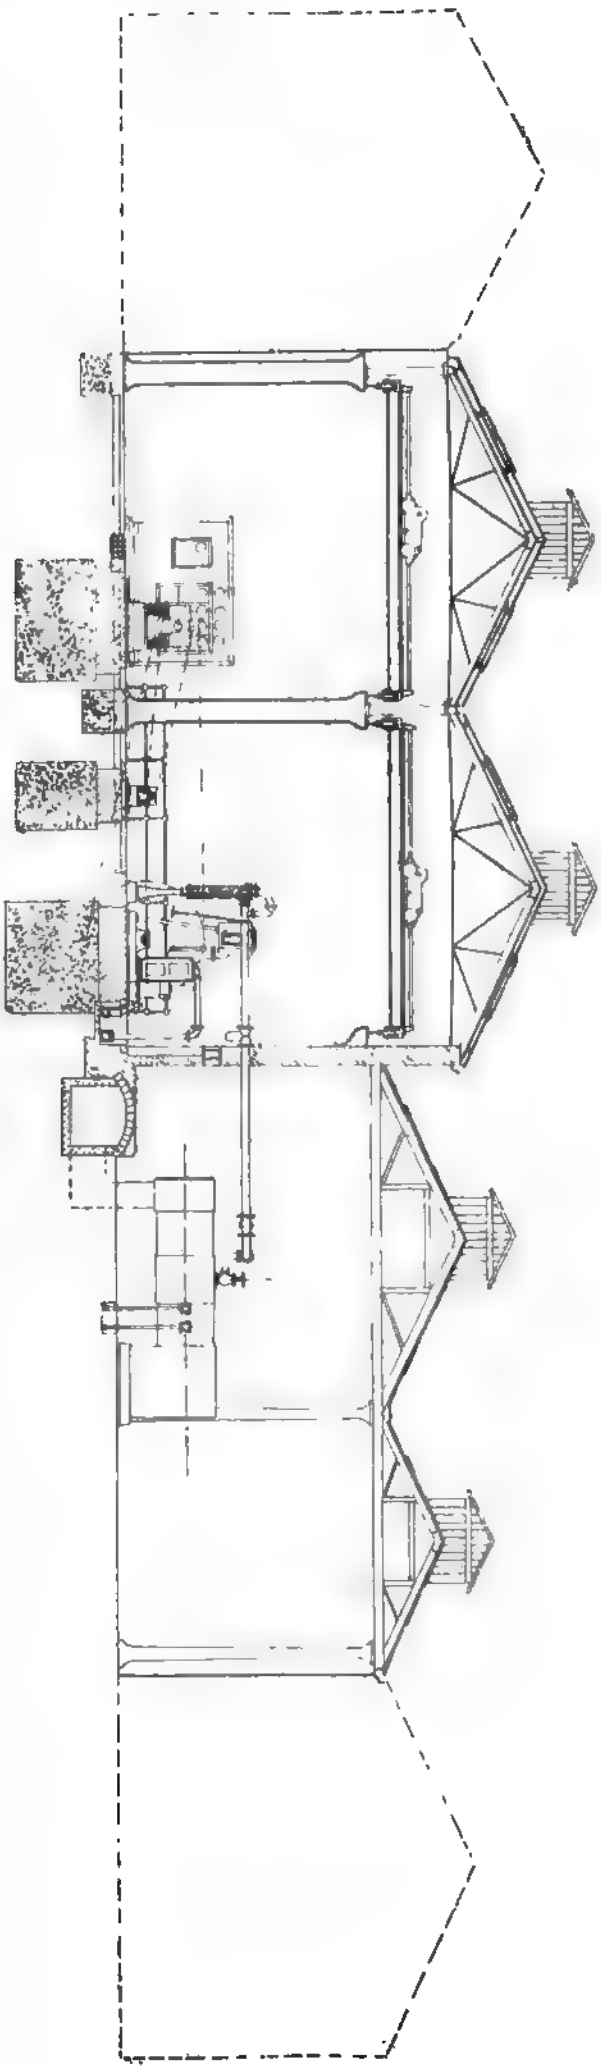

FIG. 11.—Elevation of Oxford Central Station at Osney.

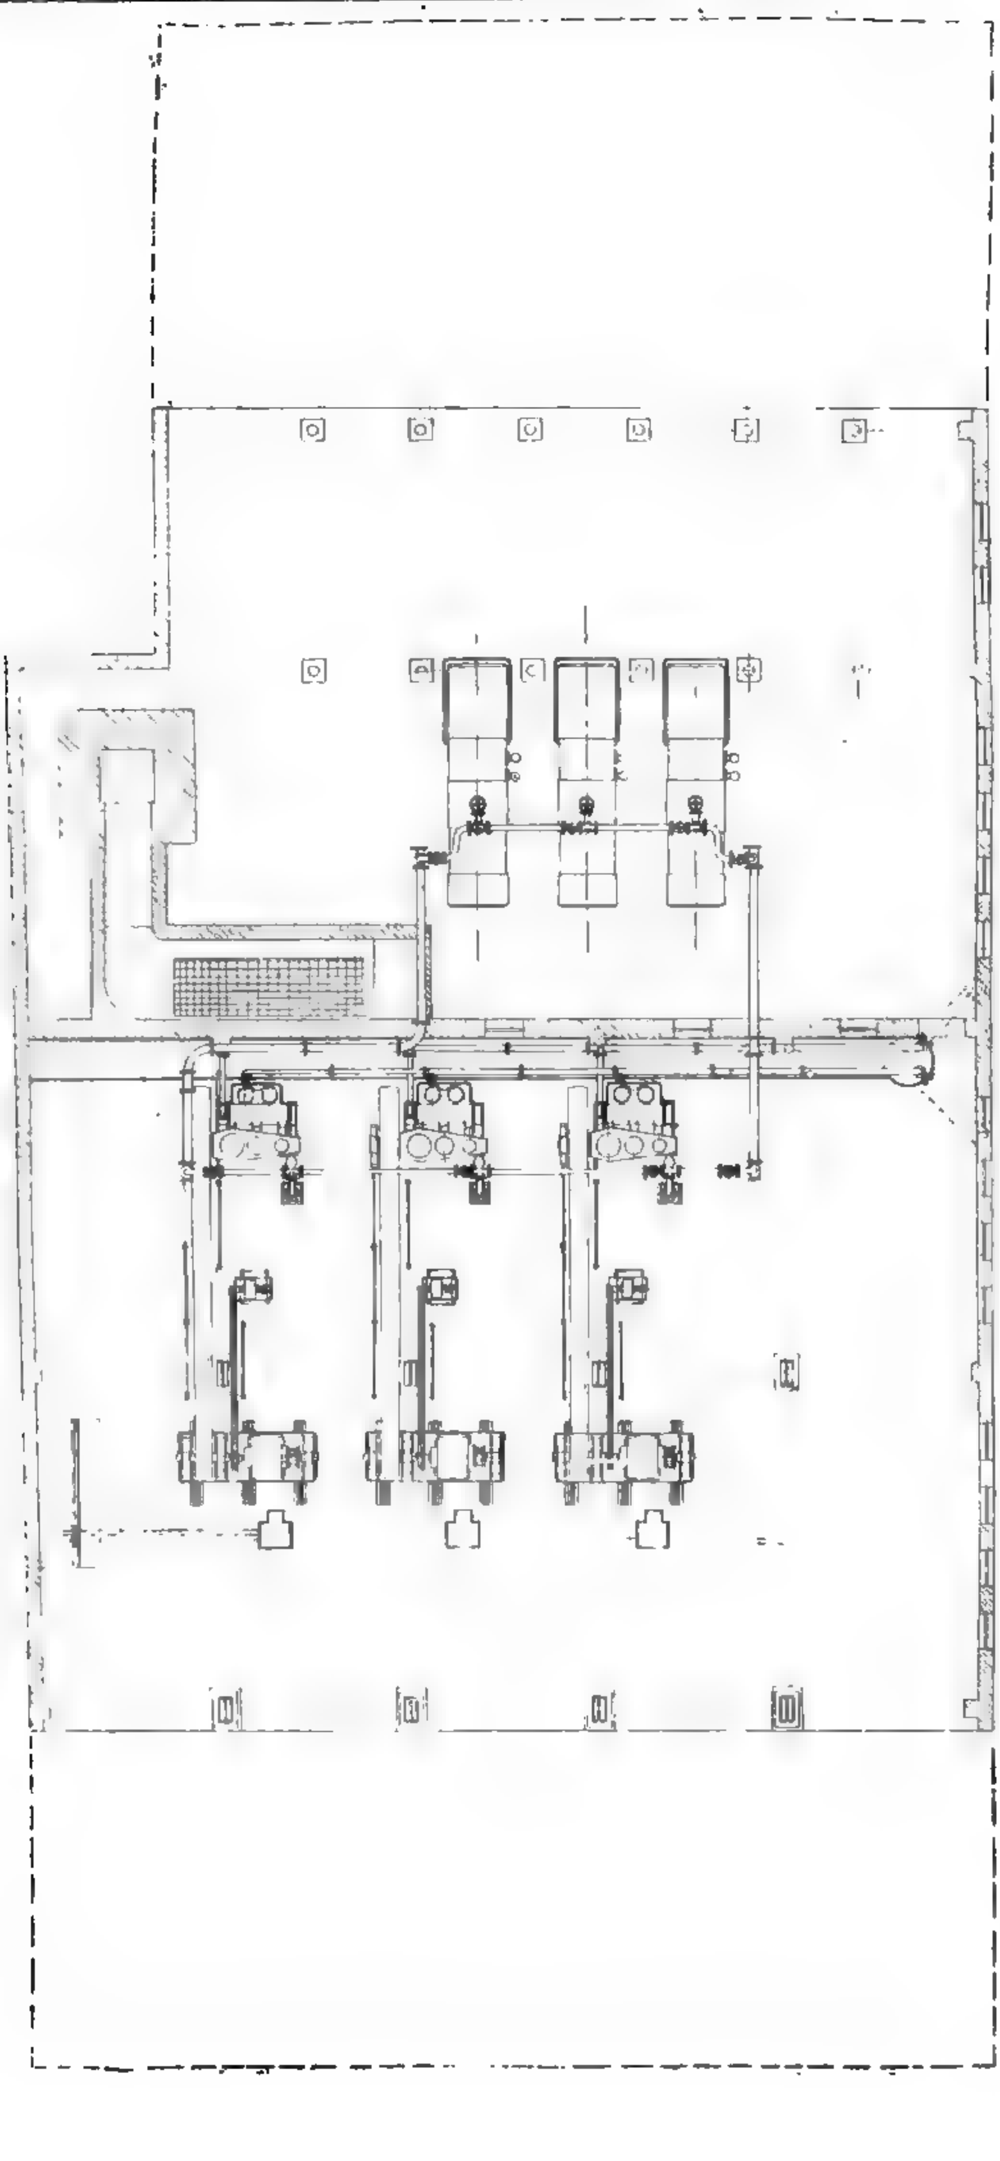

FIG. 12.—Plan of Oxford Central Station at Osney.

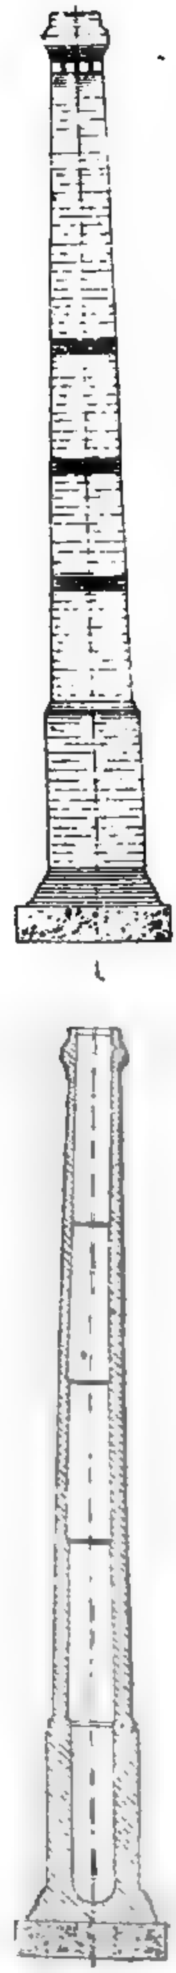

FIG. 13.—Chimney Shaft.

CENTRAL STATION AT OXFORD.

The details of this station are interesting. Our Fig. 1, page 5, showed the elevation to the river. This is built with blue brick in cement, 2ft. above high-water level to plinth, and above plinth with white bricks and red brick bands, arches, doors for unloading coal, charging launches, etc. There are 10 windows, each 5ft. by 3ft. A plan and elevation of the building is shown in Figs. 11 and 12 herewith, also sectional elevations through boiler and engine-house respectively, Figs. 13 and 14. The chimney shaft is shown in Fig. 15. The shaft is 125ft. high, square on plan, standing on a bed of cement concrete 20ft. by 20ft., and 5ft. thick, built of local bricks, with blue bands 1ft. 6in. deep every 25ft. The head is of brickwork, with York stone coping. The boiler-house, 68ft. by 51ft., is roofed in two spans on 12ft. 9in. diameter columns, framed principals, with skylights, louvres, etc., as in engine-house. The flues from boilers and economiser are partly underground. The floor is laid with Wilk's patent metallic paving. The engine-room is 80ft. by 58ft., with roof in two spans carried on eight stanchions 3ft. wide (to carry two six-ton cranes), and short columns 9in. diameter on top of stanchion, with Keay's patent iron principals and wood purlins and rafters, covered with blue slates. Ventilation is obtained by eight towers, 5ft. by 5ft. by 3ft., on the ridge, and four skylights, by 60ft. by 5ft., having wood bars and glazed with Hartley's rolled plate glass.

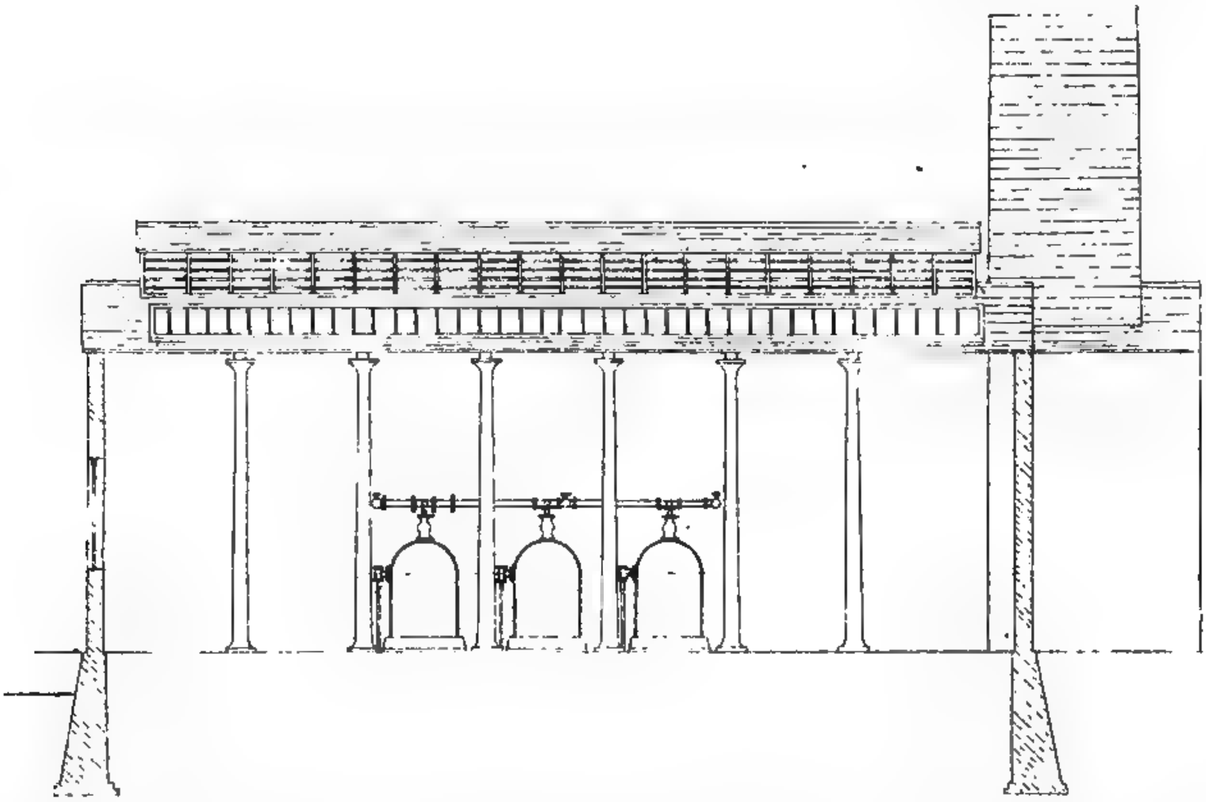

FIG. 13.—Sectional Elevation through Boiler-Room, showing also Ventilator and Skylight.

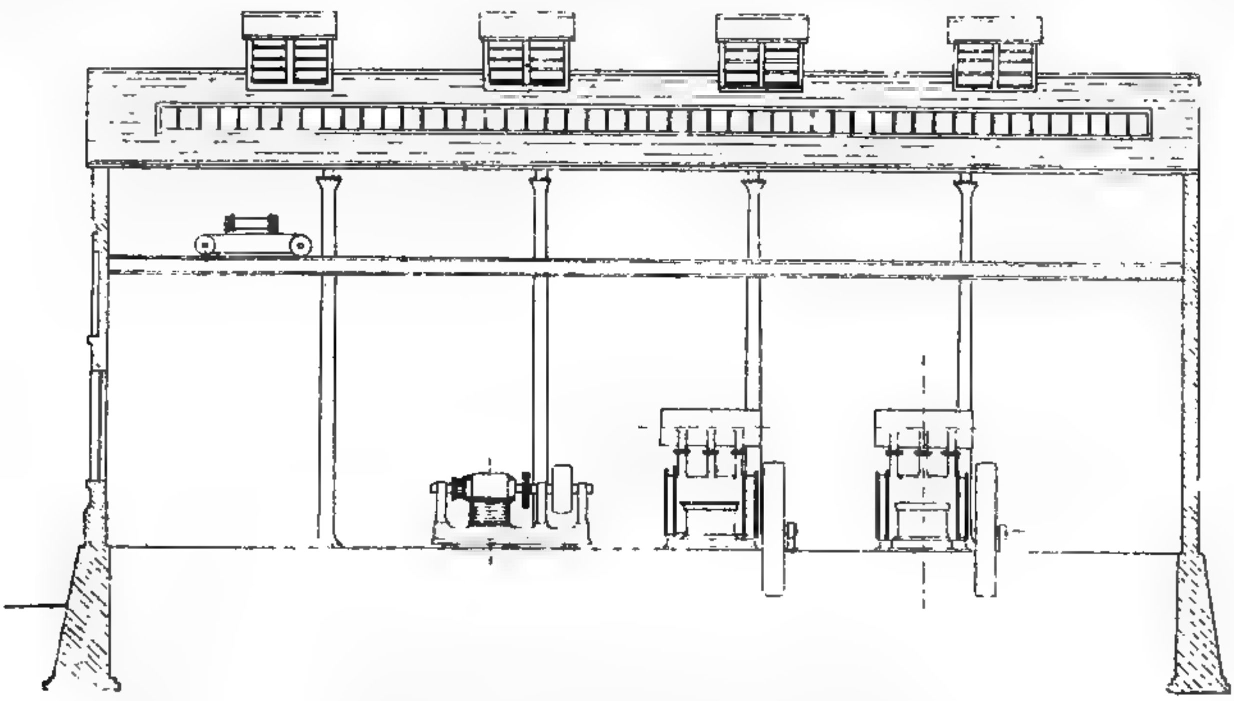

FIG. 14.—Sectional Elevation through Engine-Room, showing also Ventilators and Skylight.

The machinery and stanchions stand on cement concrete 10ft. thick, the flywheel and governor wheel races are in

Fig. 16 shows the switchboard arrangement at the central station. An examination of the illustration, and a glance at the reference letters, will make the arrangement far more clear than any amount of written description. The same may be said of Figs. 17 and 18, which show the switchboard as employed at the central switch station at

The cables which carry the current from the central station to the switch station at Broad-street are of the Silvertown Company's make. At the Broad-street station, as we have said, there are installed two sets of accumulators and a continuous-current transformer. The accumulators are capable of discharging at the rate

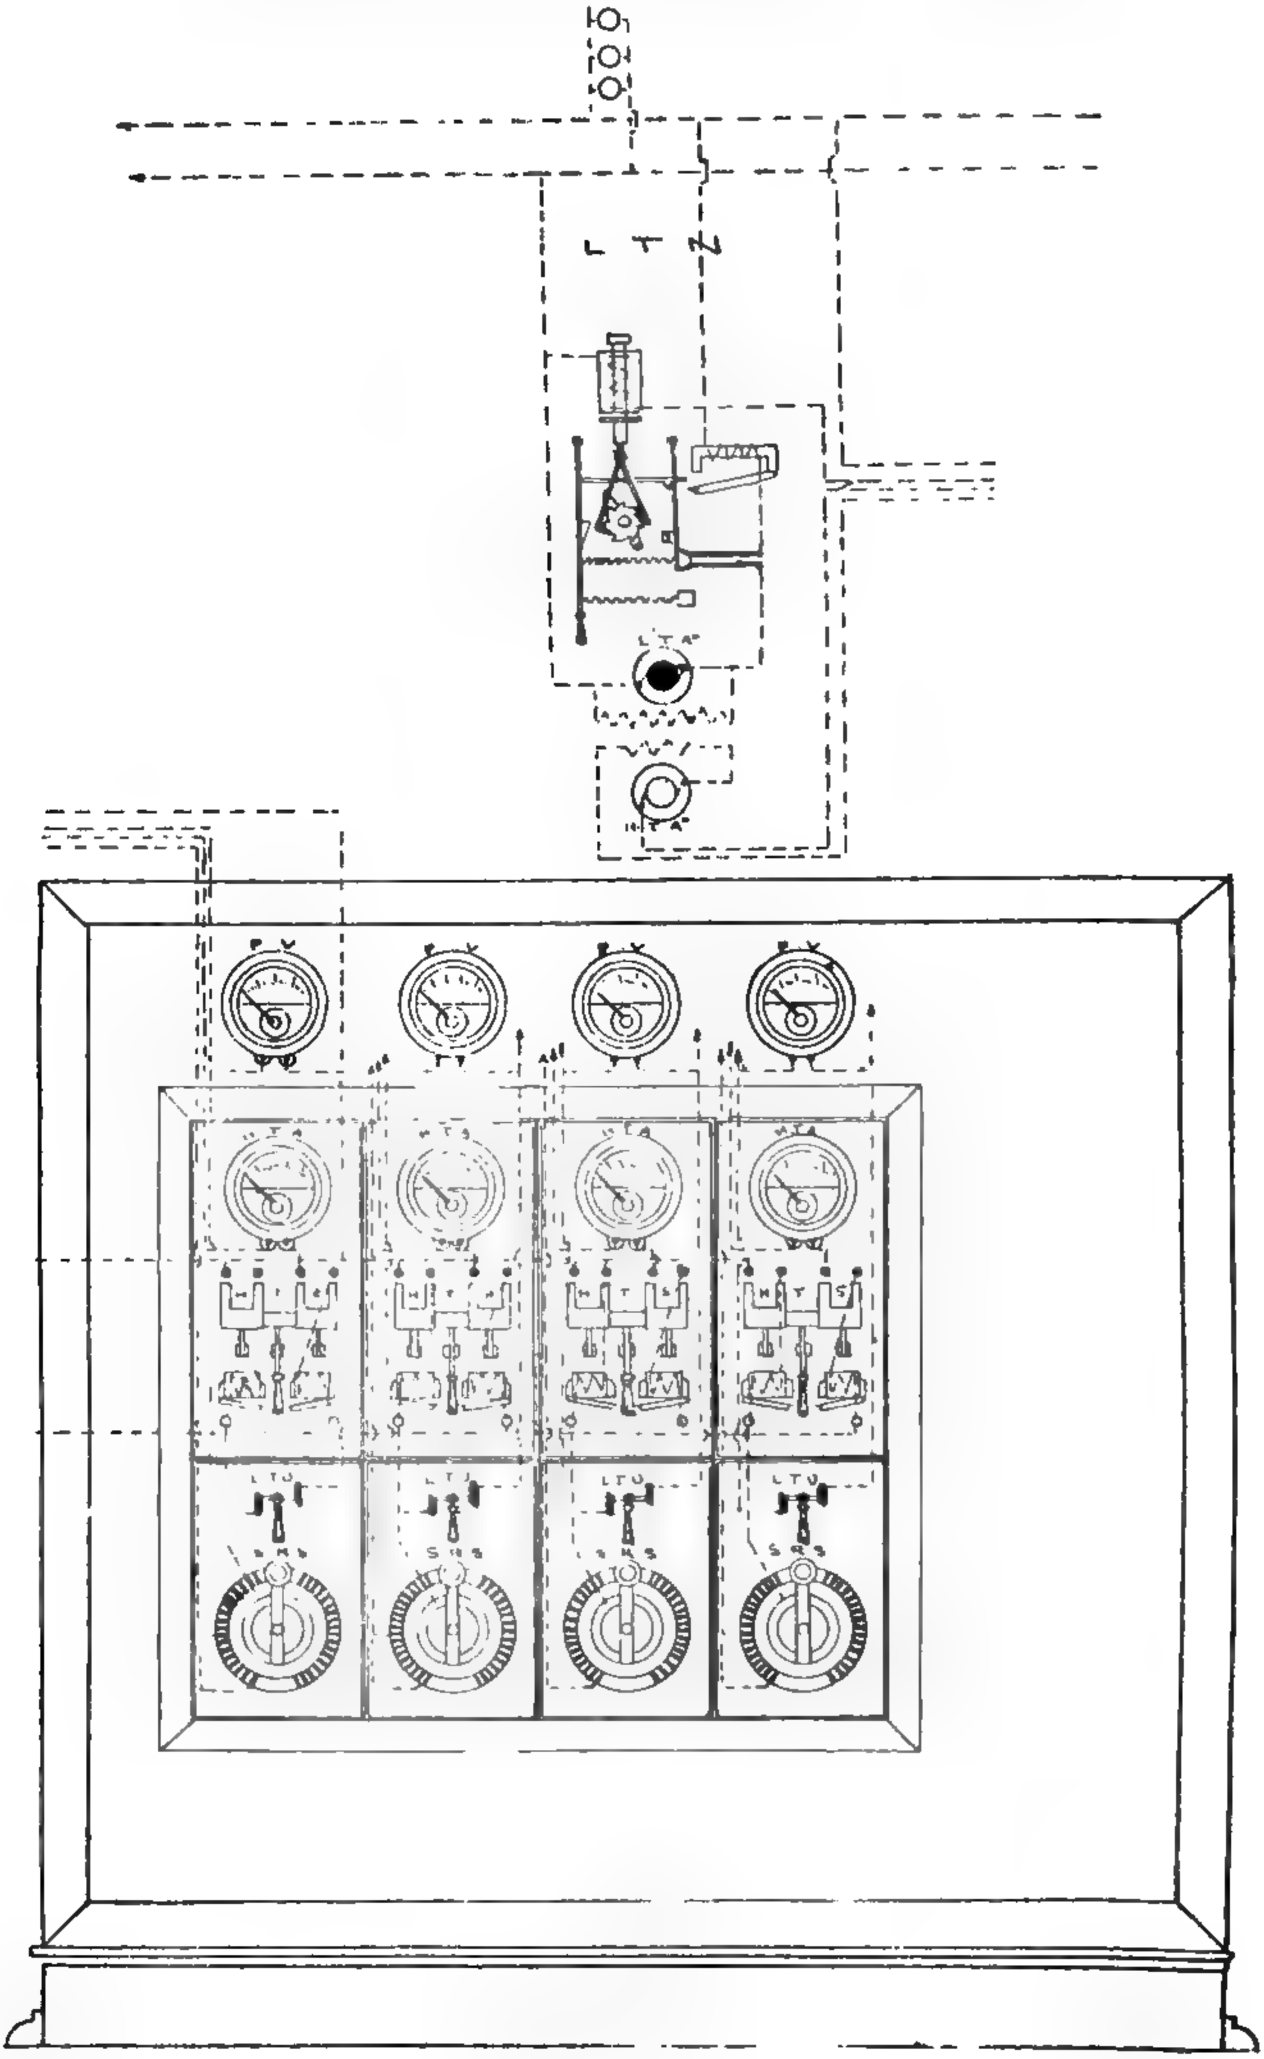

Fig 18.—Left-hand Portion of Switchboard at Central Switch Station, with Diagrammatic Illustration above of Magnetic Switch and Cut-out. (For references see Fig. 17).

120 amperes for eight hours. The transformer is designed to run from a 1,000 volt circuit, and to give 110 volts 360 amperes on the secondary circuit. All the transformers are fitted with oil pumps, and as the brushes require no lead, the machines want but little attention. Similar transformers are placed in Queen street and King street, and are started and stopped by means of the switch gear at the Broad street station. At Broad street voltmeters show the pressure in the consumers' network. When the demand requires, and it is necessary to feed from the transformer, the electrician in charge closes a double-pole switch, which starts the transformer as a series motor, the field being fully magnetised by a few turns of the high pressure mains, as was the case with the transformers in the machine-room at the Palace. A circular resistance switch allows a considerable resistance to be put in circuit at first till the motor gets up speed, and excites its own field by its shunt coils. When the shunt coils obtain their full strength, the speed is automatically kept down to 500 revolutions per minute. Fig. 19 shows a very ingenious magnetic switch and cut-out, used to put the generating circuit on to the supply circuit. A small switch at the switch station is closed, thus short-circuiting the pilot voltmeter and passing a small current through a large iron-clad solenoid coil, which is always in the voltmeter circuit. The core and iron disc of the solenoid armature carry two pawls, which engage a ratchet wheel. With the up stroke of the armature one pawl pulls a tooth and with the down stroke the other pawl pushes another tooth. The movement of the ratchet wheel actuates a cam to act on a double switch, and thus to connect the transformer to the supply mains. The circular resistance before referred to for controlling the starting current is arranged so that coils of low resistance but capable of carrying the whole current can be put into circuit to control the voltage. An automatic cut-out carrying the whole low-pressure current is provided. In the event of a heavy short circuit the armature of the solenoid is lifted, strikes a tooth of the cam, and breaks the connection between the transformer and the supply circuit. When the transformer supply is no longer needed the attendant puts a resistance into the high pressure circuit until the speed drops and the ammeter shows no current going into the mains. Then the short-circuit switch is closed and opened, causing the ratchet wheel to move round, and the cam passing forwards releases the main switch.

FIG. 19. Magnetic Switch.

FIGS. 20 AND 21. Arc Lampposts.

At the time of opening only four or five arc lamps were temporarily erected at various points in the streets. The lamps are of the well-known Brockie-Pell type. The lampposts it is arranged to erect permanently are illustrated in Figs. 20 and 21.

We must congratulate Mr. J. Ofler for his untiring energy in pushing this scheme forward, Mr. T. Parker and the Construction Corporation for the admirable work done, and trust that Oxford will respond to their advances. The way may be long, but it should be sure. So far as the design and the work is concerned there should be no doubt about its success. The only thing needed is the patronage of the Oxford public.

The National Telephone Company have decided to co-operate with the Postmaster-General with regard to the acquisition by the Government of trunk mains.

REPORT OF THE FRANKFORT COMMITTEE.

The report of the Testing Committee of the Frankfort Electrical Exhibition has been received by the directors of the exhibition, who have forwarded to us a copy of this report, embodying the figures obtained from the tests of the transmission of power from Lauffen to Frankfort.

The work of the committee extended to three installations. The first, that of the celebrated Lauffen-Frankfort multiphase-current transmission, carried out in conjunction by the Allgemeine Company, of Berlin, and the Oerlikon Company, of Zurich, comprised the transmission of power electrically from the Wurtemburg Cement Works at Lauffen, on the Neckar, to the exhibition grounds at Frankfort. The power of the waterfall was about 300 h.p., and the distance 175 kilometres (about 110 miles). The measurements were made by the members and assistants of the Testing Committee, composed of Prof. Dietrich, Dr. Feussner, Dr. Heim, Dr. Kopp, Herr Nizzola, Herr Schmoller, Prof. Stenger, Prof. Teichmann, Prof. Voit, and Prof Weber.

The second transmission of power was installed by the Deutsche Elektricitätswerke of Aix-la-Chapelle (Garbe, Lahmeyer, and Co.). The power, furnished by a 20-h.p. engine in the Palmengarten, Frankfort, was transmitted to the exhibition, where it was used to drive a motor in the exhibition; the distance was about two kilometres (about 1¼ miles), the current being high-pressure continuous. The tests in this case were taken by Prof. Brauer and Dr. Wirtz, members of committee, and Herren Friese, Stapelfeldt, and César, assistants.

The committee also examined the installation erected by Lahmeyer and Co., of Offenbach, near Frankfort, but the tests were too few to make it desirable to publish the results.

The complete description of the tests, as well as of the methods and instruments employed, will be given in the official report, which will be published when the work of the committee upon them is finished.

Table I., given herewith, gives the results of the Lauffen-Frankfort transmission; the last column gives the total efficiency—that is, the percentage of the energy supplied to the lamps at Frankfort to the energy taken from the axle of the turbine at Lauffen.

The same tests for the second transmission plant are given in Table II., the efficiency being the comparison of the work measured at the brake on the axle of the motor and the electric energy at the terminals of the generator.

The resistance of the circuit was 5·9 ohms.

The above-mentioned tables are signed: Table I., by Prof. H. F. Weber, of Zurich; and Table II., by Dr. Wirtz, of Darmstadt.

A second committee, under the presidency of Prof. Kittler and Herr Lindley, engineer to the city of Frankfort, carried out, after the close of the exhibition, another series of measurements with the idea of determining the efficiency of the plant at voltages of 25,000 to 30,000 volts, and of examining the phenomena produced under these conditions.

The report of this committee will form part of the general report of the directors of the Frankfort Exhibition.

LITHANODE TESTING BATTERY.

For many laboratory and manufacturing purposes it is necessary to have for testing purposes a high voltage. This is the case with insulated wire manufacturers, and some time since the British Insulated Wire Company, through their engineer, Mr Yeaman, late of Liverpool, had fitted up a testing set of secondary batteries to give 1,000 volts The accompanying illustration, Fig. 1, made from a photograph, shows the battery arrangement.

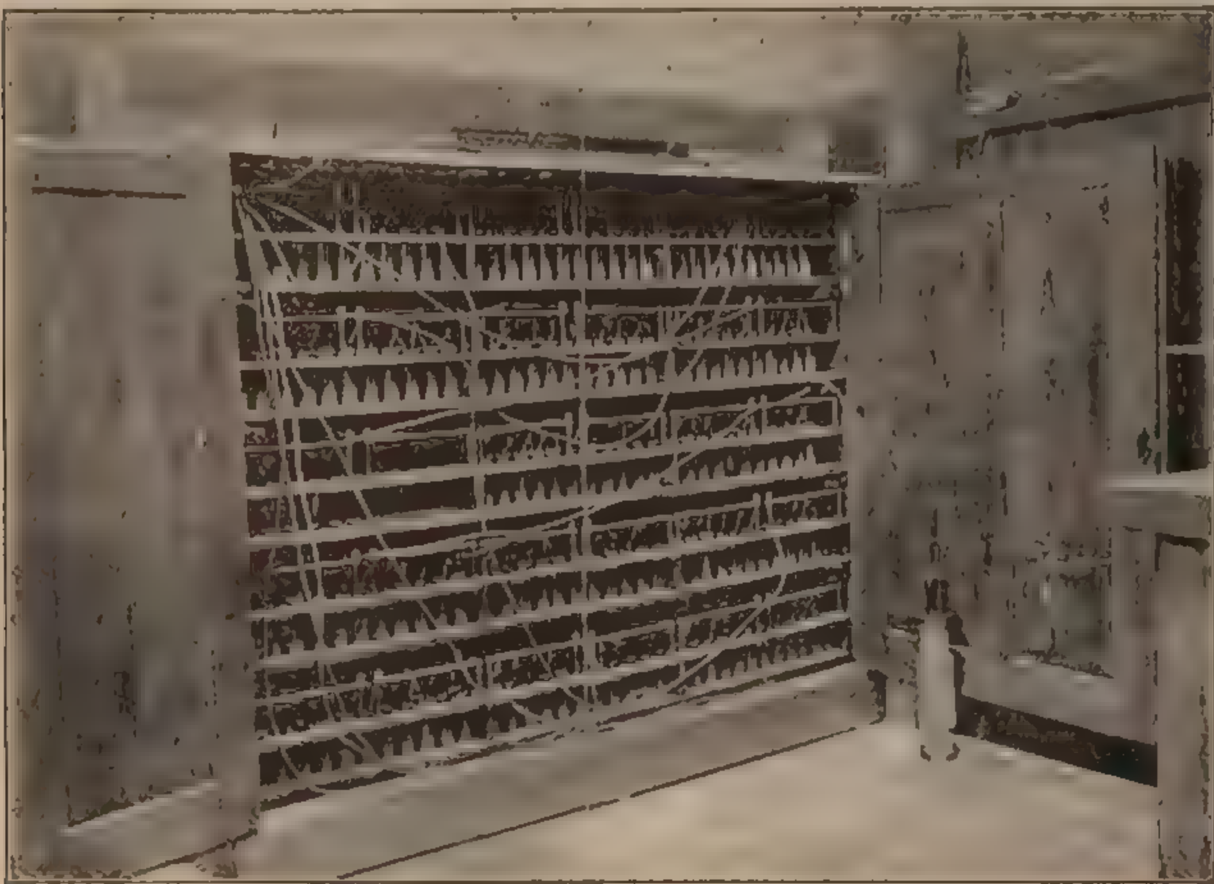

FIG. 1.

This battery consists of 500 glass cells, of the type shown in Fig. 1, mounted in sets of 100 in five trays. Each tray is subdivided into three sections of 33, 33, and 34 cells respectively. This arrangement is for convenience of charging from a 100 volt circuit. Each tray, which is constructed of a light pitch pine framework, is mounted on four small oil insulators, and the white metal connecting bars are supported on corrugated vulcanite pillars about 3in. long and ¾in. diameter. The set of five trays are enclosed within a pitch-pine wood cabinet, which is quite fume-proof. The cabinet thoroughly coated inside with shellac varnish,

FIG. 2.

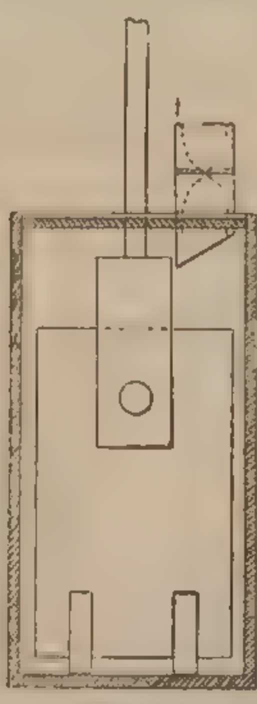

FIG. 3.

FIG. 4.

and is French polished outside, and fitted with lock and key. To ensure perfect insulation from the earth, the containing cabinet is mounted on four large oil insulators.

The capacity of each cell is just one ampere-hour if discharged at a rate of not exceeding 0·2 ampere, but the cells are capable of being discharged at a rate of from 0·5 to 1·0 ampere, with but a slight fall of E.M.F. By the arrangement of grouping, any number of volts may be obtained, commencing from 66 up to 1,000. To prevent any possibility of corrosion due to acid fumes, all the internal metallic fittings are made of a special inoxidisable white metal, and no corrodable metal of any description enters into the construction of this battery. Every precaution has been taken to ensure perfect insulation and reliability. As an example of testing battery whose cells are each capable of developing a constant E.M.F. of two volts, even when a considerable amount of current is taken from it, this battery certainly stands alone.

In actual work at Prescot, one tray per day is charged in rotation, so that the whole battery is charged once a week. The charging current is at a pressure of about 75 volts and 0·2 ampere. The insulation of the battery as it stands is about 2,000,000 ohms, quite sufficient, Mr. Yeaman says, for his ordinary work. We understand this battery, supplied by the Lithanode and General Electric Company (late the Mining and General Electric Lamp Company), has given great satisfaction, and we have no doubt its advantages, which can easily be seen, will commend themselves to other users.

In addition to the above, the British Insulated Wire Company have some sets of the vulcanite lithanode testing cells, shown full size in Figs. 3 and 4. These unique little cells are mounted in trays, containing 10 cells in each, and are therefore capable of giving 20 volts—a potential very suitable for laboratory use. These small tray batteries are exceedingly light and compact, and are, we believe, the smallest and lightest form of practical testing cell giving an E.M.F. of two volts ever constructed. In all cases the latest type of lithanode is used. This material is vastly superior to that formerly made.

TRADE NOTES AND NOVELTIES.

Our American namesake has for a long time given brief descriptions of minor pieces of electrical apparatus under this heading, and we venture to adopt the title. The decision to instal the electric light does not mean that expenditure ceases with the purchase of a dynamo, a gas engine, or a steam engine. These are the big items: there are hundreds of other items, from a staple to a meter, and the purchase of these things means business in manufacturers' shops.

Insulating Saddle Staple.

Messrs. Moses and Mitchell are introducing a staple (illustrated below) under this name, the inside bend of which has an insulating covering of vulcanised fibre. The staple is intended

to be used in fastening electric light conductors and telephone and district messenger wires in mouldings, on timber, back boards, and switchboards; also telegraph wires in towers and offices; also burglar alarms, annunciator and all other low pressure wires within the walls of buildings, especially in basements and places liable to moisture. The insulating saddle staple will not cut the insulation of wires, either by the immediate action of the driving blow, or subsequent gradual pressure on the compressed and somewhat flexible wrapping, and therefore the consequent leakage, either to ground or the opposite pole, over the surface or through the mass of partially conducting supports, or by direct contact of the staple with ground or a conductor, is done away with, and the electrolytic action set up between the copper and iron by the presence of moisture and tending to transfer a portion of the copper through the covering and deposit for some distance around the naked metal staple, which action results in eating away the wire finally to a needle point, heating the reduced section until it melts and arcs, with a probability of setting the surroundings on fire, is entirely avoided.

PROVISIONAL ORDERS.—SESSION 1892.

With the ending of Parliament there is, of course, an ending of the provisional orders that will be confirmed this year, but fairly good progress has been made, and a number of provisional orders have been confirmed, as may be surmised when we state that there are no less than six electric lighting orders confirmation Bills. Those six Bills deal with the following:

Bill 1. Govan Electric Lighting Order, 1892, the undertakers being the Commissioners of Police and the Borough of Govan, the area of supply being the borough of Govan.

Bill No. 2 confirms the Aberystwith order, promoted by the Corporation of Aberystwith, the area of supply being the municipal borough. Ashton-under-Lyne, promoted by the Corporation, for the supply of the borough. Halifax, promoted by the Corporation, for the supply of the borough. Similarly, Harwich, Limerick, and Maidstone.

Bill No. 3 deals with Kilkenny, promoted by the Corporation of Kilkenny, for the supply of the borough. Also Newbury, promoted by the Corporation, for the supply of the borough. Sutton (Surrey), the undertakers being the Local Board, and the area of supply being the urban sanitary district of Sutton. West Ham, by the Corporation, for the supply of the county borough of West Ham. Woking, promoted by the Woking Electric Supply Company, the area of supply being a portion of the parish of Horsell and a portion of the parish of Chertsey.

Bill No. 4. Dublin, promoted by the Corporation, for the supply of the city. Fareham, by the Fareham Electric Lighting Company, for the supply of the district of the Fareham Urban Sanitary Authority. Liverpool, by the Liverpool Electric Supply, the area being a portion of the city. Oxford, authorising the transfer to the Oxford Electric Company. Sheffield, by the Sheffield Electric Light and Power Company, for the supply of the borough. Waterford, by the Corporation, for the supply of the borough.

Bill No. 5 confirms various undertakings promoted by the County of London Electric Lighting Company. The undertakings refer to the County of London work, the area being the united parishes of St. James's and St. John's, Clerkenwell, and the parish of St. Luke's, Middlesex; Southwark, the area of supply being the parish of St. George the Martyr, Southwark; Wandsworth, the area being that of the Wandsworth District Board of Works.

Bill No. 6 confirms the Hampstead order, undertaken by the Vestry of St. John's, Hampstead. Lambeth, also undertaken by the Vestry, to supply the parish. Shoreditch, undertaken by the Vestry, for supplying the parish of St. Leonard, Shoreditch. Whitechapel, undertaken by the Whitechapel District Board of Works, to supply the district.

THE VARLEY TESTIMONIAL.

A meeting was held at the Westminster Palace Hotel on the 1st July for the purpose of discussing the subject of the Varley testimonial. A considerable number of gentlemen were present, including Lord Kelvin, Major Flood Page, Mr. A. Siemens, Profs. Hughes, Perry, Silvanus Thompson, Forbes, Messrs. Gatehouse, Crompton, Stroh, Gorman, and others. Lord Kelvin took the chair.

A number of letters were read from gentlemen who were unable to attend, but who had signified their hearty assent with the objects of the meeting. Among these were Sir F. Bramwell, Sir H. Mance, Sir Leppoc Cappel, Sir D. Galton, Sir J. Pender, W. H. Preece, Prof. Ayrton, Prof. Kennedy, Dr. Gladstone, Prof. Lodge, Prof. Fitzgerald, Messrs. J. W. Swan, Belshaw, J. E. H. Gordon, Manville, Massey, R. K. Gray, Jackson, and Goolden.

Mr. Gatehouse then gave a very interesting account of Mr. Varley's life, and the services that he has rendered to electrical engineering.

After some remarks by **Mr. Crompton, Major Flood Page,** and **Mr. Siemens**, the following resolution was put and carried:

"That this meeting approves of a testimonial being got up on behalf of Mr. S. Varley, that the whole of these gentlemen who have given their names as willing to serve on the committee be and are hereby appointed a committee to act in the question of the Varley testimonial, and that an executive committee be hereby appointed, consisting of Lord Kelvin, Prof. S. Thompson, Prof. Perry, Mr. A. Siemens, and the gentlemen who attended the preliminary meeting."

Among other matters it was suggested that the aid of the Insti

tution of Electrical Engineers be sought to ask that the Government should grant a pension to Mr. Varley, and, further, that a statement setting forth what Mr. Varley has done should be prepared by Messrs. Siemens, Gatehouse, Silvanus Thompson, and Crompton, and this statement should be circulated as widely as possible among members of the electrical profession at home and abroad. That the general committee should consist of the names of the gentlemen who had attended the preliminary meeting, also those who had attended that day, and all the gentlemen who had written expressing their sympathy with the objects of the meeting, and that every effort should be made to extend the list.

LEGAL INTELLIGENCE.

H. F. JOEL AND CO. v. BARNET LOCAL BOARD.

The award in the arbitration between Messrs. H F Joel and Co., of 31, Wilson-street, London, and the Barnet Local Board, in which Messrs. Joel claimed compensation for breach of contract, was taken up by Messrs. Joel and Co. on Friday last, June 30, and was entirely in favour of Messrs. Joel and Co., who obtain £500 as damages, and their costs in the reference, and the costs of the award.

The arbitration proceedings were taken by Messrs. Joel and Co. for certain alleged breaches of the contract between themselves and the Barnet Local Board. Messrs. Joel undertook, under somewhat exceptional circumstances, to light the streets of Barnet with electric light for three years, at a cost, light for light, less than had been paid for gas, and, owing to the very short time allowed to do the work, they undertook to fix temporary plant and overhead wires, to be replaced within 12 months by permanent plant and underground wires, the consideration being that the Barnet Local Board were to give them the sole right to supply the private lighting for the three years, and a perpetual but not a sole right thereafter to continue so to supply the private lighting. The Barnet Local Board undertook to consent to Messrs. Joel having a license or provisional order, if necessary, to carry out the lighting. Messrs. Joel fitted the street lamps in an exceptionally short time, and started the light on September 1st, 1888, as agreed, but when, in the following April, the Local Board were asked to give their consent to the application to the Board of Trade for a license they refused their consent, although just previously they had been urging Messrs. Joel to take the license, and had actually agreed and did call a meeting to give such consent. This refusal completely stopped Messrs. Joel putting their wires underground, and of course they were unable to supply the private customers. The overhead wiring was not intended to be other than temporary, but it had to stand for the three years of the contract, and in the first two months of the lighting was the cause of several failures, which were much advertised to the prejudice of Messrs. Joel and Co. Messrs. Joel and Co. contended that such refusal of the Board to carry out the terms of the contract was a breach of that contract, and towards the end of the three years commenced the arbitration, with the result as first stated. Messrs. Joel and Co. completed their part of the contract to light for three years, in spite of the difficulties and opposition thrown in their way.

Mr. John Fell was the arbitrator for Mr. Joel, and Mr. Slater for the Barnet Local Board, whilst Mr. Lumley Smith, Q.C., was the umpire. Messrs. Ingeldew Ince and Colt, representing Mr. Joel, instructed Mr. Robson, Q.C., and Mr. Poole, the solicitor to the Barnet Local Board, instructed Mr. Fletcher Moulton, Q.C., and Mr. Gordon. The arbitration proceedings occupied many days, and many witnesses were examined, amongst them being the following electrical engineers—Mr. Preece, Mr. Probert, Mr. Howard Swan, Mr. Potter, Mr. Sennett, and most of the members of the Local Board

We understand Messrs. Joel and Co., immediately after taking up the award on June 30, gave the formal notice to the Barnet Local Board of their intention to apply in the forthcoming session for a provisional order under the Electric Lighting Acts of 1882 and 1888.

Mr. Preece's evidence was to the effect that on the two occasions upon which he saw the electric light at Barnet "the lighting was everything that could be desired"

NEW COMPANIES REGISTERED.

Electric Lamp Company, Limited.—Registered by H. W. Christmas, 42, Bloomsbury-square, with a capital of £4,000, in £1 shares. Object: to carry on business as manufacturers of electric lamps and electric apparatus generally. Registered without special articles

London Electric Manufacturing Company, Limited.—Registered by S. Morse, 4, Fenchurch-avenue, E.C., with a capital of £10,000 in £1 shares. Object sufficiently indicated by the title. With slight modifications, the regulations contained in Table A apply.

New Firm.—We understand that Messrs. Fowler and Gate have established themselves as electrical engineers at 20, Bucklersbury, and intend to pay special attention to the requirements of wiring and fitting interiors, especially in the City. Both Messrs. Fowler and Gate have had long experience with the Brush Company, and should thoroughly understand the work they will be called upon to do.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 1 were £2,701.

Telegraph Construction and Maintenance Company.—An interim distribution of 12s. per share is announced.

Eastern Extension Telegraph Company.—The receipts for June amounted to £41,738, as against £39,749 in the corresponding period, showing an increase of £1,989.

City and South London Railway.—The receipts for the week ending July 3 were £763, against £719 for the same period of last year, or an increase of £44 The total receipts to date from January 1, 1892, show an increase of £1,293, as compared with last year.

London County Council.—Notices of mains to be laid and connections to be made, in accordance with rules and regulations, were before the Council on Tuesday from the Electricity Supply Company (mains across Panton street and on west side Oxendon-street and across that street to Prince of Wales Theatre); St. James and Pall Mall (various service lines); Kensington and Knightsbridge (service lines); House to House (service lines); Notting Hill (service lines); and Westminster Electric (service lines).

London Chamber of Commerce.—Notice is given that a meeting of the Electrical Trade Section will be held at the offices on Friday, the 8th inst., at 3.30 p.m., to consider the appended agenda, when a full attendance is particularly requested. Agenda.—(1) Minutes; (2) report of special committee appointed to consider the County Council by laws on overhead wires; (3) report as to the action taken by the special electrical traction committee; (4) report of the special Chicago Exhibition committee; (5) standardising of machinery; (6) uniformity of prices; (7) foreign competition; (8) other matters.

Pacific Cable.—Says *Trade and Finance*: "A very interesting registration at Somerset House last week was the Pacific and European Telegraphic Company, Limited, formed under the auspices of Sir John Pender and Sir James Anderson, to carry into effect an agreement between the Brazilian Submarine, Western and Brazilian West Coast of America, and the new company for the construction and maintenance of telegraphic communication between Buenos Ayres, Valparaiso, and Santiago." If there is to be another company, it will be wise to see that the "pickings" are somewhat less than they were out of the "Metropolitan."

Electric Organ Company.—An attempt is being made to promote a company called the Hope Jones Electric Organ Company, with a capital of £25,000 in 1,200 cumulative preference shares of £10 each, and 1,300 ordinary shares of £10 each. The patents to be acquired are No. 15,461 of 1890, and 18,803 of 1890. The payment for these is £3,000 cash, and 1,300 fully paid up ordinary shares. The Directors are of opinion that the balance of the issue of 1,000 cumulative shares—viz., £7,000—will be enough working capital. Far be it from us to stop investors, but we have not much faith in the future prosperity of a company when £13,000 of share capital and £3,000 in cash is given for patents for the application of electricity to organ work. The scope of the Company cannot be very wide; but organ-building is not exactly in our line, and the Company appeals more to the musical than to the electrical world.

Edison and Swan Electric Company.—At the Board meeting on Tuesday it was resolved: "That, subject to audit, the shareholders be recommended to declare a dividend on the A shares of the Company of 5s. 8¾d. per share on the 89,261 ordinary shares, £3 paid; of 9s. 6¼d. per share on the 5,000 £5 fully paid shares allotted to the Edison Electric Light Company, Limited; and of 8s. 10¾d. per share on the 12,139 £5 fully paid shares allotted to the Swan United Electric Light Company, Limited, free of income tax, being, with the interim dividend paid on the 22nd February, 1892, 7 per cent. in respect of the year ending 30th June, 1892; 7 per cent. in payment of arrears of cumulative preferential dividend for the year ending 30th June, 1887; and of 4 per cent. in respect of the year ending 30th June, 1888; all to be distributed in accordance with the provisions of clause 87 of the articles of association."

National Telephone Company.—The report for the year ending April 30 states that the income amounted to £463,741, as compared with £431,112. The working expenses and other charges (excluding debenture and other interest) amounted to £236,252, an increase of £38,768. The net result for the year, after deducting the Post Office royalties, amounting to £40,239, is a profit of £187,249, a decrease of £7,797. It must, however, be remembered that at the end of 1890, in view of the expiration of important patents, a reduction of the tariffs in most of the Company's districts was carried into effect. Upon the business of the past year, this reduction has been equivalent to a cession of about £55,000 to the subscribers. Further attention may be called to the fact that the rentals carried forward this year for unexpired terms of running contracts amount to £234,370, an increase of £29,938. Out of the divisible balance, after providing for interest on debenture stock, an interim dividend for the first half-year has already been paid at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the ordinary shares. The Board recommend a further dividend for the last half-year at the rate of 6 per cent. per annum on the first and second preference shares, and 7 per cent. per annum on the ordinary shares, making, with the interim dividend, 6 per cent. for the year. They propose to transfer to reserve account £10,000, which, with £1,127 placed to reserve during the year from premium account, will bring up the amount of the reserve fund to £194,627.

PROVISIONAL PATENTS, 1892.

JUNE 20.

11487. **An apparatus for erecting top and middle sections of telephones and other poles.** Robert Frederic Jeffries, 26, High street, Wimbledon, London.

11525. **Apparatus for use in manufacturing electric cables.** George Gatton Melhuish Hardingham, 191, Fleet street, London. (Felten and Guilleaume, Germany.)

11526. **Improvements in electric cables.** George Gatton Melhuish Hardingham, 191, Fleet street, London. (Felten and Guilleaume, Germany.)

11528. **Improvements in dynamo-electric machines and motors.** Johannes August Carl Ziegler, William Rupert Rutledge, and Francis Erskine Allan, 70, Chancery lane, London.

11532. **Improvements in secondary or storage batteries.** Wilhelm Alexander Boese, 6, Lord street, Liverpool.

JUNE 21.

11548. **Improvements in connection with lubricators used on dynamo-electric and similar machinery.** Charles Scott Snell and Woodhouse and Rawson United, Limited, 88, Queen Victoria street, London.

11592. **Means for operating ammeters and other electrical apparatus.** Clyde Kennedy Mills, 23, Southampton buildings, Chancery lane, London. (Herbert Morris Pilkington and Roger Sherman White, United States.)

11617. **Improvements in or relating to dynamo machines.** Charles James Hall, 433, Strand, London.

11624. **Improvements in coin-operated telephone apparatus.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Eloy Noriega, Mexico.)

11634. **Improvements in or relating to electric railways.** Frank Wynne, 46, Lincoln's-inn-fields, London.

11640. **Improvements in electric meters.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 24, Southampton buildings, Chancery lane, London.

JUNE 22.

11664. **Improvements connected with tubular electric conductors and their insulation.** Ernest Payne, 39, Victoria street, Westminster, London.

11672. **Improvements in armatures for alternate-current dynamo-electric machines and motors.** Rookes Evelyn Bell Crompton and Sydney Linton Brunton, 53, Chancery lane, London.

11692. **Improvements in electric locomotives.** Frederick Purdon, Harry Ernest Walters, Basil Mott, and John Patrick O'Donnell, 2, Great George street, Westminster, London. (Complete specification.)

11698. **Improvements in insulators for overhead and other electric wires.** Fritz Meyer, 18, Buckingham street, Strand, London. (Complete specification.)

JUNE 23.

11735. **Improvements in and connected with electric dynamo machines distribution by means of transformers, organs, and the reduction of zinc.** James Swinburne, Broom Hall Works, Teddington.

11779. **Improvements in the manufacture of carbons for electric arc lamps.** George Frederick Redfern, 4, South street, Finsbury, London. (Carl Braun, Germany.) (Complete specification.)

JUNE 24.

11807. **Improvements in and relating to the measuring of electricity, and in meters therefor.** Rankin Kennedy, 96, Buchanan street, Glasgow.

11822. **Improved means for electrically winding up the weight for driving clockwork and other mechanism.** Hermann Aron, 6, Lord street, Liverpool.

11823. **Improvements in apparatus for measuring electric currents.** Hermann Aron, 6, Lord street, Liverpool.

11835. **Improvements in the process and apparatus for tanning hides and skins with electrolytic action.** Etienne Jean Finot, 28, Southampton buildings, Chancery lane, London.

JUNE 25.

11849. **Improvements in distribution and branch boxes for electric circuits.** Sigmund Bergmann, 70, Wellington-street, Glasgow. (Complete specification.)

JUNE 27.

11941. **Improvements in electricity meters.** Herbert Woodville Maher, 2, York mansions, Earl's Court, London. (Complete specification.)

11948. **Improvements in electric fire alarm and circuit controlling thermostat and clock mechanism.** Harvey Cortland, 52, Chancery lane, London. (Complete specification.)

11962. **Improvements in electric meters.** John William Jones, 13, Dornton road, Balham.

JUNE 28.

11969. **Telegraphic including telephonic communication between lightships and the shore.** Joseph Henry Hirst, 77, Bettingham street, Kingston upon Hull.

12039. **Improvements in the construction of electric railways and appliances therefor.** Thomas Floyd, 11, Furnival-street, London.

12040. **Improvements in and connected with arc electric lamps.** James Eglington Anderson Gwynne, 11, Furnival-street, London.

12044. **Automatic supply of electricity.** George Horatio Jones, 57, Great Russell street, Bloomsbury, London.

12057. **Improvements in printing telegraphs.** Samuel Rush Linville, 323, High Holborn, London. (Complete specification.)

JUNE 29.

12087. **Improvements in electric heating devices and contacts for the same.** Friedrich Wilhelm Schindler-Jenny, 8, Quality court, Chancery lane, London.

JUNE 30.

12191. **Improvements in electric railways.** Benjamin Joseph Barnard Mills, 23, Southampton buildings, Chancery lane, London. (Edward Hibberd Johnson, United States.) (Complete specification.)

JULY 1.

12212. **Electric regulating apparatus.** Julien May Bradford, 6, Monroe place, Portland, Maine, U.S.A.

12238. **Improvements in and apparatus for producing and utilising electric currents.** Bernhard Scarr-Drauer, 33, Chancery lane, London. (Complete specification.)

12246. **Improvements in electrical meters.** Yvan Arthur Marie Prosper Goulaux, 23, Southampton buildings, Chancery lane, London.

12258. **Improved electric glow lamp.** Paul Scharf, 28, Southampton buildings, Chancery lane, London.

JULY 2.

12295. **Improvements in electric arc lamps.** William Habgood, 19, Chandos road, Buckingham.

12306. **Improvements in the construction of secondary batteries for electrical storage purposes.** John Bridges Lee, 3, Brick court, Temple, London. (Complete specification.)

12311. **Improvements in electric theft-prevention alarms.** Charles Darrah, of the firm of Baxendale and Co., and Thomas Joseph Gough, 70, Market street, Manchester.

SPECIFICATIONS PUBLISHED.

1886.

14105. **Electric signalling for railways.** Walker. (Second edition.)

1891.

7781. **Converting electric currents.** Boucherot.
11113. **Electromotors, etc.** Lahmeyer.
12525. **Electrical steering gear.** Grimston and Dykes.
13124. **Heating and welding by electricity.** Howard.
13250. **Electrical switches.** Wheatley. (Andalek.)
13252. **Electrical contact making and breaking devices.** Fox and Ducretet.
13331. **Telephony.** Kellogg.
13367. **Electric telephone switches, etc.** Sloper.
13802. **Electric current generator.** Sohlman.
13927. **Printing telegraphs.** Van Hoevenbergh.
14500. **Electrical transmission of power.** Muir. (Leonard.)
19495. **Electrical conduits, etc.** Powers and Van Buren.

1892.

2055. **Closing electric circuits.** Wise. (Bertolini.)
5034. **Electrically controlled elevators.** Johnson. (Hiss.)
6181. **Electric fire alarm.** Woolley.
6722. **Secondary batteries.** Donaldson and Macrae.
7415. **Electric propulsion of vehicles, etc.** Dewey.
8242. **Electrically propelled vehicles.** Hawkwander.
8535. **Electrical hose signalling apparatus.** Fowler.

NOTES.

Gravesend is to have a new technical school.

Poole.—The electric light is installed throughout the new town offices at Poole.

La Charente.—The docks at La Charente, France, are to be lighted by electricity.

Lewisham is to have a new infirmary, and will probably adopt the electric light.

Zurich.—A company has been formed in Zurich for the purpose of establishing central stations in that town.

Glasgow.—Mr. John Young has been appointed general manager of the Glasgow tramways, at a salary of £1,250 a year.

Electric Harpoon.—The idea has again arisen of electrically attaching the harpoon to an alternating current, and thus to shock the whale.

Honolulu Cable.—The survey for the cable between San Francisco and Sandwich Islands has been completed. The length from Hilo is 2,060 miles.

Berwick.—The Berwick Town Council have appointed Mr. C. R. Templeton, of Gateshead, consulting engineer, to draw up a plan for lighting by electricity.

Niagara.—It is stated that 50,000 h.p. will be ready for use in October at Niagara, and that dynamos for 10,000 h.p. for transmission have been ordered.

Barnsley.—The proposal to establish a central station, at a cost of £18,382, and to apply for sanction to borrow the money, will come up at the next meeting of the Council.

Islington. — Extensive premises at Islington and Willesden Green are advertised in the daily press suitable for electric light purposes by Segrave and Taylor, 117, Holborn.

Brake Blocks.—In electric, as well as tram and other railways, brake blocks are used. We notice that lignum vitæ is being used for this purpose with good results in lasting power.

Sevenoaks.—A letter was received and read at the last meeting of the Sevenoaks Local Board from the Board of Trade, enclosing notice of revocation of the electric lighting order.

Glasgow.—The new Municipal Buildings have cost a total of £529,909. 7s. 8d. Of this the electric installation cost £2,209. 12s. 8d., and the electric and gas light fittings £4,008. 7s. 8d.

Tariff.—E. Dieudonné has an article which may interest central station managers in *L'Electricien* for July 9, on how the tariff for current should be regulated upon the demand and other data.

Fulham.—The Fulham Vestry is of opinion that a polytechnic institute should be erected in the parish, and have appointed a committee to carry out the resolution embodying this opinion.

Electric Power Storage.—Electrical engineers will be pleased to see the good business that is being done by the E.P.S. Company, whose gross profit of £37,000 odd allows a dividend of 6 per cent.

Electric Crane at Woolwich.—The General Electric Power and Traction Company, Limited, have received instructions from the War Office to erect a five-ton electric travelling crane at Woolwich Arsenal.

The Elections.—The electric light signals of the election results shown at the National Liberal Club were on the Roman letter system of Mr. C. E. Kelway. An effective illustration of the scene appears in this week's *Black and White*.

Colliery Work.—The General Electric Power and Traction Company, Limited, have added another dynamo to the extensive plant at Messrs. Locks and Co.'s St. John's Colliery, Normanton. The machine was started on Saturday last.

Colliery Lighting.—The General Electric Power and Traction Company, Limited, have received instructions to light the New Hemsworth Colliery, near Halifax. The plant consists of a 300-light dynamo, and the necessary wiring and fittings.

Belgium.—A project is being mooted to change all the smaller branch railways in Belgium—*chemins de fer vicinales*—from steam to electric traction. Such a project, if carried out, will give a great impetus to the extension of electric railways.

Guildford.—There seems to be a desire among the members of the Council to push forward the question of electric lighting. At the last meeting it was decided that Mr. Shoolbred's report should be printed and circulated among the members.

Liege.—An electric street railway, belonging to the Tramways Company of Liège, is being built by the Compagnie Internationale d'Electricité of Liège, and will be opened in October. There will be two compound-wound dynamos as generators.

Burnley.—The Board of Trade has extended by six months the time allowed in which to put down the electric lighting installation. There seems to be no reason now why specifications should not be got out at once, tenders obtained, and operations commenced.

Edinburgh.—At the meeting of the Council on Wednesday, a letter was submitted from Mr. Holroyd Smith, inviting a deputation of the Council to Bradford to inspect the electric tramway there. The subject is to be dealt with by the Lord Provost's Committee.

"Electrical World."—We were pleased to welcome to England last week Mr. W. J. Johnston, the genial proprietor of the *Electrical World* of New York. Mr. Johnston usually makes a trip to Europe every two years, and this time is accompanied by his wife and children.

Explosion.—Another explosion, seemingly attributable to gas leakage, took place on Saturday last week, this time at Bournemouth. The damage was slight, and the fact that the fuses were not melted made it evident there had been no short-circuit. A strong smell of gas had been previously noted.

Paddington.—The Metropolitan Electric Supply Company has written to the Paddington Vestry on the subject of their accounts. After Colonel Blair had expressed his opinion that the company were trying to wriggle out of their contract with the Vestry, the matter was referred to him and to Colonel Blanchard to deal with and to act.

Leith.—At the meeting of the Dock Commission a report was submitted regarding the proposal to introduce the electric light at the docks. It was estimated that the installation would cost £10,000, and that the annual cost, including depreciation of plant, would be £2,300. The report was remitted to the Works Committee with powers.

Newcastle-on-Tyne.—Tenders are required by July 19 for the electrical lighting of the whole of the warehouses and offices, Newcastle-upon-Tyne, for the Committee of the Co-operative Wholesale Society, Limited. Information can be obtained from the society's engineer, Mr. John Thompson, C.E., Post Office-chambers, Newcastle-upon-Tyne.

Claybury Asylum.—The Asylums Committee of the London County Council reported, at the Tuesday's meeting, recommending that they should be authorised to accept tenders for electric lighting of Claybury, and additions to Banstead and Cane Hill Asylums during the recess. This was agreed to. Tenders are to be sent in by July 26th.

Crystal Palace Awards.—We understand that considerable dissatisfaction is found in the method, manner, and result of the giving of awards at the Crystal Palace Exhibition. Some of the exhibitors say that the puzzle has been even to find the jurors, and, in fact, though they have been hunting after them for weeks, they were never able to find any of them.

Epstein Accumulators.—That these are making steady progress is evinced by the fact that the Birmingham Central Tramways Company have just placed an order for 600 Epstein cells with the Midlands branch of Messrs. Woodhouse and Rawson United, Limited, at the Minories, Birmingham, the cells being for use upon their important electric car route in that city.

Vaultage.—Heard in the City:—First Man: "They'll soon have the full number of 2,000 volts on the City electric lighting mains, they say." Second Man: "Ah, so many; well, I don't wonder: they've put one vault opposite my place for the wires, and a fine old mess, too. I shouldn't wonder if there were 2,000 of em scattered about. I suppose that's where they store it."

Weymouth.—An application was read at the Weymouth Town Council last week from the secretary of the Aurora Electric Lighting and Distribution Company, asking for the consent of the Urban Sanitary Authority to an application they propose to make for a provisional order to supply the town with electric lighting, and for other purposes. The application was not entertained.

Brillie Meter.—An order has just been received by the Compagnie Anonyme Continentale of Paris for a Brillié meter, fitted with diagram recorder, for 2,000 volts up to 30 amperes alternating current, for the Chelmsford central station. As the same company last year made a meter for 2,000 amperes and 100 volts, they claim to have constructed the two largest meters yet put in action.

Oxford.—At last week's Oxford City Council a letter was read from the secretary of the Ashmolean Society, in reference to the co-operation of the Council in giving an invitation to the British Association to hold its meeting in Oxford in 1894. After a short discussion, it was resolved that the Mayor, Colonel Swinhoe, and the town clerk should form a deputation to give such invitation to the association.

Personal.—Mr W. J. Hammer, who has for some time past been on this side as representative of various American electrical interests, returned to America on the s.s. "Majestic" on Wednesday last, owing to important business matters necessitating his presence on the other side. Mr. Hammer expects to return to England again in a short time, and meanwhile all communications should be addressed to Temple-court, Room 533, New York.

Tercentenary Celebration at Dublin.—Amongst the distinguished representatives of science, literature, and art who have attended the Trinity College tercentenary, Dublin, were the following well-known electrical names: Lord and Lady Kelvin, Lord Armstrong, Sir F. Bramwell, and Profs. Ayrton and Perry. Amongst those who have received honorary degrees, it is interesting to note the name of Mr. Henry Irving, who has received the distinction of Doctor of Laws.

City Lighting.—The Board of the City of London Electric Lighting Company, Limited, give notice that the supply of current will be available, both day and night, on and after the 1st August. Colonel Haywood, at the Commissioners of Sewers meeting, in answer to a question, stated that the mains were laid in nearly every chief thoroughfare and some others. Mr. Johnson thought the work in the City was about half done. A plan was kept which could be inspected by the members.

Whitby.—At the last meeting of the Local Board Mr. Brown said he was informed that they some time since spent £412 in obtaining an electric lighting order, and he thought that some use should be made of it. He moved that the Electric Lighting Committee be requested to take steps to consider the desirability of applying the order in Whitby. They were paying £1,000 a year for gas, and this order had cost them £412. What were they going to show for it? Mr. Raine seconded the motion, which was carried, and Mr. Brown was added to the committee.

Lane Fox Patents.—Before the Privy Council on July 7, the petition by Mr. Lane Fox for prolongation of patent was dismissed. Lord Hobhouse pointed out that before there could be a prolongation of a patent the Judicial Committee must report to her Majesty that the patentee had not been adequately remunerated. It was the rule that full accounts must be laid before the Attorney-General, and afterwards before the Judicial Committee. The petitioner submitted that the accounts in this case were as full as possible. After some discussion their Lordships dismissed the petition on the ground that the accounts were insufficient, and, on the application of Mr. Wallace, they granted one set of costs.

Rockhampton, Queensland.—The secretary of the Rockhampton Gas Company writes that we were too previous in the statement in our issue of April 22, reporting the acceptance by the municipality of the offer of a Sydney firm for electric lighting. The gas company has secured the right by Act of Parliament to supply the town with electricity, and has submitted proposals to the Town Council with this end in view. The company has erected a central station, which, with necessary plant, will cost about £10,000. Bravo! gas company. On May 31st, according to an official letter of the town clerk, now before us, the Council has not decided about the offer of the gas company, but, of course, would not entertain any other offer till that was disposed of.

Cranes at Chicago.—Four of the principal makers of travelling cranes are to place cranes at the Chicago Exhibition, in such a manner that passengers can be carried over Machinery Hall and obtain a bird's-eye view of the exhibit. The length of course run by each crane will be 1,400ft., and the cranes will all be operated by electricity, and travel at the rate of 300ft. to 500ft. per minute, if the latter speed is required. The purpose of these cranes is not entirely for the pleasure of visitors, as they will be erected in the autumn of this year and used in placing the exhibits. The trolleys will then be removed from the cranes while they are in use for passengers, and after the conclusion of the exhibition the exhibits will be removed by the help of these same cranes.

Popularising Electrical Knowledge.—It is singular how little real knowledge about electrical matters has as yet diffused among the public, hence we welcome all such popular expositions as that of Mr. A. Fahie in *Health Record*. One of his points is directed against cheap fittings for electric light purposes. "Cheap and nasty" is proverbial, but it is extremely difficult to counteract the buying of such materials. Increased knowledge

made by the returning officer at Ealing by the flashing of two of Ronald Scott's well-known search-lights of 30,000 c.p. each, was most successfully carried out in every detail. The two projectors were placed on the roof of The Elms, Mr. Scott's residence at Acton Hill, which is at about the same level as St. Paul's. Before the returning officer had finished his announcement both beams of light were sweeping the country round. One search-light was then manipulated to signal the actual figures into Acton and on to Chiswick at the same time, the signalman at Chiswick being stationed at the top of the Fire Brigade tower, a distance of 2½ miles from the source of light. The majority was first signalled, and then the numbers polled by each candidate, but although accurately signalled and read, the signalman at Chiswick was so astounded at the enormous majority of Lord George Hamilton that he awaited confirmation by bicycle from Ealing before giving out the result. The time occupied in transmission was less than four minutes.

Electric Light in Ireland.—The editor of the *Waterford News*, in order to show Waterford what has been done elsewhere, has written to Dublin and Carlow to ask how the electric lighting is going on in those towns. The answers received are interesting. Mr. Spencer Harty, city surveyor, Dublin, says: "In reply to the queries relative to the electric lighting, I have to say that the present installation is confined to some of the leading thoroughfares of the city, and will not, at least for the present, be extended to the narrow thoroughfares. We have received a great number of applications for private lighting, and expect to have the full load of our plant in operation." Mr. James Kelly, town clerk of Carlow, says: "The electric light is going on very well here, and giving most general satisfaction. The narrow streets are lit with it. We have principally incandescent lamps in these streets, and arc lamps in the principal thoroughfares. As to the difference in the cost of this light and gas, I cannot well say, as Carlow was lighted by oil for the past 15 years. Shopkeepers are taking in the light every day. Our agreement with the contractors is for three years; but we have—so far only as we have lawful power and authority so to do, but no further or otherwise—conceded to them the sole right of public and private lighting of the town for the space of 21 years, but our contract for lighting is terminable after three years and may be renewed. We did not advertise for contractors; the firm sent in an estimate in November, 1890, which was accepted by the Commissioners without the advice or opinion of an independent engineer. We never had a printed report on the lighting, as it was not thought necessary."

Acton Hill Electrical Works.—The fourth annual sports of the Acton Hill Electrical Works were held on Saturday last, the 9th inst., in the grounds behind the works, by kind permission of Mr. Ronald Scott, the president. Everything passed off well, the occasion being enlivened by the large number of the fair sex present. The band of the 4th Volunteer Battalion East Surrey Regiment were on the ground, and played up to their usual standard of excellence. It was proved that the athletic element was not wanting in the works, Mr. E. H. Turrell and Mr. A. Patey showing themselves very fast at the 100 yards and ¼ mile respectively. Mr. H. Squire carried off the pole jump, long jump, high jump, putting the weight, and throwing the cricket ball in very fine form. There were two bicycle races, one for solid and one for pneumatic tyred machines, the former being won by Mr. B. Chilton, and the latter by Mr. G. Hickman. The competitions terminated with "walking the greasy pole" over a large pond in the grounds, which event caused, as may be imagined, great amusement, the flag being finally secured by Mr. G. Robarts. At the conclusion of the sports, Lady Nares very kindly distributed the prizes, an event which added greatly to the *éclat* of the proceedings. Mr. Ronald Scott afterwards moved and Captain Kay seconded a vote of thanks to Lady Nares, which was carried with acclamation. The visitors then paid a visit to the shops, and inspected the machinery in motion and work in course of erection, and were further interested in various electrical experiments. This brought the proceedings to a close after a very enjoyable afternoon. The sports were carried out under the able management of Mr. J. H. Garratt, assistant electrician to Mr. Scott.

Barnsley.—The chief interest at the last meeting of the Town Council centred in the electric lighting question raised on the report of the Park and Lighting Committee, which recommended: 1. That the electric light be installed on a site in Beckett-square, at an estimated cost of £18,382, but that at present only £13,332 be expended. 2. That Mr. A. Bromley Holmes be appointed electrical engineer, and that he be instructed to prepare all plans, specifications, and estimates of the electrical plant, and that the borough surveyor be instructed to prepare the plans, specifications, and estimates of the requisite buildings, and that such plans and estimates be submitted to the committee as early as practicable. 3. That application be made by the Council to the Local Government Board for their sanction to borrow the said sum of £18,382. These recommendations were based on a report made to the committee by the borough surveyor (Mr. J. H. Taylor) after a very full investigation of the subject by himself and the committee. In the report two schemes are submitted—the first for a nominal output of 2,500 8-c.p. lamps, and 28 1,200-c.p. arc lamps for street lighting, with 2 miles 93 yards of mains and feeders laid underground, and the second for a nominal output of 5,000 8-c.p. lamps, of 31 1,200 c.p. arc lamps, with 2½ miles of mains and feeders laid underground. The first scheme embraces Regent-street, part of Church-street, Market-hill, Peel-square, Eldon-street, Kendray-street, Mayday Green, Cheapside, Queen-street, part of Sheffield-road and Newland, a length of 1¾ mile; and the second adds Peel-street to the area, making 1⅞ mile; and with mains and feeders laid in Shambles-street. No. 1 scheme covers 45 and No. 2 ... acres, containing 11 houses of more than £20 a year rateable annual value; 252 shops, 11 mills, workshops, and chapels. Probably consumers for 2,500 8-c.p. lamps would be obtained in a year, especially as the Harvey Institute would require 1,000 such lights. Scheme No. 2 would cost £18,382, and if fully worked would yield a profit of £1,428. 18s. per year, half the number of lamps in use would give a profit of £181. 6s.

Accumulator Traction.—At the meeting of the London Tramways Company at Camberwell Green on Monday, Mr. David P. Sellar, the chairman, complained that the carrying power of the company had practically come to an end, at any rate until the cable was started. A large sum had been borrowed on debentures to pay for the alterations. It was impossible to carry passengers more cheaply than the company did. The number carried during the past half year was 33,700,000. This was considerably more than they carried in the financial year ended 11 years ago. The buildings at Streatham Hill were not completed. They hoped to have the cable in working order during the next two months, and that they would be able to show a good return for it at the next meeting. On Colonel Davidson seconding the adoption of the report, an amendment

was proposed for a committee to go into the financial position of the company. After some discussion the report and balance-sheet were adopted, the amendment finding no seconder. Mr. H. C. Clements then moved: "That the time has arrived when it will be much to the interest of the shareholders that there should be no unnecessary delay in substituting electric cars for horse cars, and that it was the wish of the shareholders that the directors should enter into an arrangement with an electric company for the alteration of the present cars into electric cars and the supply of the necessary electricity; or that they themselves should alter the existing cars into electric cars and provide the necessary electricity, and as quickly as the electric cars could be obtained and supplied with electricity they should be used upon the road." The chairman, in reply, made the statement that there was not a single accumulator tramway running—everywhere the system was a failure. Mr. Luther Clements seconded the motion, which was rejected. This instructive passage shows very forcibly both the desire of the shareholders to take up electric traction, and the necessity for the production of a reliable accumulator—accumulator cars being the only kind most companies desire. It is a pity the company, while altering their line, could not have introduced the slot system of electric cars, which have proved so successful in the hands of Messrs. Siemens at Budapest.

Forcing Vegetables by Electricity.—Electricity, a writer in the *Horticultural Times* tells us, is about to find full employment in horticulture. Spring vegetables are already being forced by its aid for the market. There is no doubt that roses and other flowers can be made to bloom more plentifully and more profitably with its assistance. In short, the discovery affords promise of possibilities not yet estimated. It has been found that lettuce is particularly susceptible to the influence of the electric light, by means of which it can be grown for market in two-thirds the usual length of time. Other vegetables respond likewise in varying degrees. But everything depends upon the proper regulating of the light, and how to do this can only be learned by careful study of the results produced under all sorts of conditions. The effects of electricity being to hasten maturity, too much of it causes lettuce to run to seed before the edible leaves are formed. It must not be imagined that electricity is employed for such purposes as a substitute for sunlight. It is merely used in a supplementary fashion. The greenhouse that has the sun in the daytime is illuminated at night with arc lights, toward which the plants incline their leaves and flowers, accepting quite innocently these artificial counterfeits of the orb of day. It was supposed hitherto that vegetables required intervals of darkness for their health and development, just as animals need sleep, but it has been shown that, supplied with electric rays, they will go on growing thriftily between sunset and daybreak; staying up all night seems to do them no harm so long as the dissipation is properly regulated. The electric gardener employs opal globes to diminish the intensity of the light. When it is left bare and admitted to shed its unfiltered rays upon the plants, the latter grow pale, run up quickly in sticky stalks, and soon die. It remains to be discovered exactly how much electricity is beneficial, and during precisely what period of the development it ought to be applied. The influence of electricity upon the colour and productiveness has been shown to be extraordinary. Tulips exposed to its light have deeper and richer tints, flowering more freely, and developing longer stems and bigger leaves. Fuchsias bloom earlier under like conditions. Petunias also bloom earlier and more profusely, growing taller and more slender. It is the same way with many other flowers. In fact, there is every reason for believing that the electric light will be very profitably used in future as an adjunct to forcing establishments for both flowers and garden vegetables.

The History of Telephone Enterprise in Belgium.— Mr. Conyngham Greene, of the British Legation in Brussels, has lately written a report on the history and progress of telephone enterprise in Belgium, from which it appears that up to 1883 the telephone service in that country was in the hands of private companies, and the uncertain character of the concessions granted by the State checked the free expansion of private enterprise. Between 1880 and 1883 three separate telephone systems were in operation in Brussels, but, owing to competition and the refusal of the companies which worked the lines to grant mutual subscriptions over the lines of their rivals, no great success was obtained by any of them. In 1883 the State Department of Posts and Telegraphs took the initiative in organising and developing the telephone system of the country. A law was then passed authorising the Government to undertake themselves, or to concede on fixed conditions to others, the establishment and development of telephone lines. The uncertain and temporary character of the previous concessions gave place to a certain and regular system, and the effect was immediate. In a few months the Bell Telephone Company bought up the two rival companies of Brussels, and secured a concession not only for the capital itself, but also for Ghent, Antwerp, Verviers, and Charleroi. The company started with a paid-up capital of £105,400, of which more than two-thirds was devoted to buying up the rival plant and apparatus, and replacing that which was worn out and inefficient. The existing wires were replaced by phosphor-bronze wires on the Montefiore system. Owing to the superior capability of this wire for bearing a strain, it was found possible to diminish the number of supports, and thus to get rid of much useless material. Moreover, the expense of repairing the wires was materially reduced as breakages were of very rare occurrence, and the interruption of the service proportionally unusual. By way of dividend the company distributed in 1889 among its shareholders £10,750, and £15,181 in the following year, while the number of subscribers rose from 4,051 on December 31, 1888, to 4,726 in 1892. The State has also laid and worked lines of its own to the less important centres, which were somewhat neglected by the companies. A system of receiving and transmitting telegrams by telephone to subscribers has been introduced and has proved a great success. At present the repurchase of all the telephone concessions by the State is impending, and will probably take effect from January 1 next, when a further large extension of the telephone system will take place. The Belgian experience is that the telegraph and the telephone do not injure each other, but that both systems must be in the same hands to enable the universal extension of the telephone system to pay. It appears, however, that in regard to Press messages between Paris and Brussels the telephone has wholly supplanted the telegraph, and the same is true to a large extent of Press messages generally. The head of the technical department of the Belgian telegraph and telephone services stated the principle of successful administration to Mr. Greene in these words: "The telegraph and telephone service must be one great monopoly, and that monopoly must be in the hands of the State."—*Times*.

COMING DEVELOPMENT IN ELECTRIC RAILWAYS.

BY FRANK J. SPRAGUE.

[This is the inaugural address to the American Institute of Electrical Engineers, and is well worth careful attention.]

It is a trite but mistaken saying that electricity is in its infancy. It dropped its swaddling clothes when Morse sent the first telegraphic message. It put aside dresses and pinafore when the dynamo and arc light were invented. The incandescent lamp, the telephone, the art of welding, the transformer, are incidents of buoyant youth. The modern electric motor and electric railway mark a vigorous manhood. The truly marvellous development of electric applications of every kind, the accomplishment of many things which in ignorance of the very art, or lack of knowledge of what are now well-known facts, and more particularly the great commercial development of the transmission of power, whether for stationary purposes or for electric railways, has led to many a foolish prediction and idle boast. This is no age of inspiration, nor time for hopes never to attain fruition. It is above all things a practical age, perhaps too practical, but, nevertheless, one in which commercial enterprise, to be successful, must promise either a new field of development or economise in older fields. As the orthodox few have been waiting in sublime faith for many centuries, and will wait for many more, for the fulfilment of ancient prophecies, so too will impracticable electric enthusiasts wait for the millennium when investments are boundless, performances limitless, and efficiences unity.

It would, perhaps, have been proper in making my inaugural address to so representative a body as that of the electrical engineers, that I should touch upon the special discoveries and experiments which have recently attracted attention, but there have been so many enthusiastic and brilliant workers that neither the time at my disposal nor the knowledge I possess would permit me to do justice to their work; hence, it seems better to take up a subject with which I have been more particularly identified, which to-day commands so much attention, and concerning which there are so many conflicting opinions. While finding encouragement in the past achievements of our profession, I think the time opportune for a word of caution.

Electric street railways are no longer experimental, nor is their success problematical. Their history for the past five years is that of an almost unequalled development. Almost within a decade has occurred the first working of a practical electrical railway. In a third of that period there have been put in operation or are under contract more than 450 roads, equipped with nearly 6,000 cars, over 10,000 motors, and with over 3,000 miles of track. There is made a daily mileage of not less than 700,000 miles, and over a billion passengers are carried annually. At least 75,000,000dols. have been invested in this industry alone. Thirty thousand horses in a single year have been relieved from the slavery of street car propulsion; stables are disappearing, and streets becoming cleaner; luxurious cars are running on smooth, well-built, and rigid road beds. Dividends have been increased, expenses reduced, investments enlarged, the unproductive have become productive, the impossible possible. Land values have been increased, habitable limits extended, homes created, and time saved. We no longer hear seriously of the dangers of the trolley wire, the failure of service. The time has come when legitimate investment is amply warranted. Electric street railway construction has become a matter of engineering, not experiment. Not only have the smaller towns adopted what is the only available means of current supply, but the larger cities are following their example. St. Louis and Baltimore, Minneapolis and St. Paul, Buffalo and Rochester, Boston and Brooklyn have fallen into line, and latterly even Philadelphia seeks an improved street service, and in New York public interest is being aroused. In the latter city it is, of course, impossible to tell how successful will be the attempt to introduce electric propulsion. There is there a strong, and in many respects a legitimate, objection to overhead wires. Many unsightly poles and badly-strung wires have disappeared, and their places are taken by an underground service.

The general feeling of opposition to poles and wires ought not, however, to act as a barrier to such reasonable and proper introduction of an overhead system of supply, as the conditions now existing in that city very properly warrant. I have frequently pointed out the fact that the greatest good can come of the greatest number, especially in the over-burdened condition of transit which there exists, if certain of the lines were electrically equipped; wherever, in fact, there would be no street obstruction. In broad streets, where the tracks occupy only a small portion of the street and are near together, a line of poles of ornate design, with arms projecting on either side, can follow the centre of the street, the same poles being used for lighting. Such a street, it seems to me, is Eighth-avenue. Then, too, where there is a middle division or park, such as exists in many boulevards, and which is now used for telegraph poles, there is opportunity for an electric construction which would be entirely unobjectionable. On streets occupied with elevated structures, these structures themselves could be used for a practically rigid overhead system.

Among the numerous places in New York where an overhead system could be put in perfect operation are Central Park, West, the boulevard from Fifty ninth-street, up, a part of the First and Second Avenue lines, the Third, Sixth, and Ninth Avenue lines, and all the suburban extensions from the annexed district. I am not sufficiently familiar with the streets of Chicago, which is the last other remaining city which must consider electric street railways. In these larger cities, however, one condition should be insisted upon, and if this condition is not in the proper spirit, then much of the objection which has been raised against an overhead system must necessarily disappear. The construction must be of the very best. The only overhead line allowed should be a contact wire with sufficient strength; the main conductors and the feeders should be put underground in proper conduits. There would then be overhead only a wire necessary for the smallest duty, and of the requisite strength.

Impressed by the great development of this industry, and brought face to face with the changes it has wrought, the query is continually made, Will the electric motor replace the steam locomotive? It is similar to the older questions: Will the telephone replace the telegraph? Will the electric light annihilate the gas system?; and in all soberness a like answer can be made. It will not, but it will, as the electric light, and as the telephone have done, create a field of its own, and will replace a portion of the service now done by steam. It seems to me that the growth of electric railways will proceed something in this order: First, the street systems in the various towns, then connecting lines between adjacent towns following the lines of highways, then longer connecting lines, even on the tracks of the existing steam lines, or growing bolder, on exclusive rights of way on the same order. Then will come suburban traffic on a larger scale, and freight transfer systems, and finally the more ambitious projects of trunk line service under limiting conditions, such as I will specify.

It has been very properly said that a man will make the first long rides on electric railways by transferring from one town system to another through connecting links, rather than on individual roads. This is precisely the process by which great steam systems have been built, although, of course, starting on a larger scale, and it is but natural that this shall be one step in the development of electric railways. But evidently this natural process of evolution does not offer scope enough for the more enthusiastic, and we are now and again treated to an ideal electric road to be built on plans boldly defying both geography and the abodes of civilisation. An air line route, according to rules of surveying, allowed only in Russia and on the desert of Sahara, abolition of grades and street crossings, rigid and continuous rails; loaded cars of light weight, each operated by its own motor, and making few or no stops, unlimited potentials and undiscovered resistance to insulation, new physiological and engineering laws; indestructible machinery; unheard of powers of braking and new methods of

train operation and signalling; around all, a clear atmosphere, above all a perpetually smiling heaven, and behind all an unlimited bank account and the unlimited confidence of the investor.

Such are some of the characteristics of such a road, but perhaps it is but fair to ask, given some of these conditions, what would be the capacity of steam traction? No one will question the capacity of a motor to do the necessary work required, or to make a speed superior to that of the steam locomotive provided sufficient energy be delivered to its terminals, but we must deal with existing or probable methods of supply. It is true that the speed at which a train is propelled by steam has only increased about 50 per cent. in 60 years, for in 1832 the "Matthew Baldwin" often made a speed of a mile in a minute; but we must not confound speed with power, for while the maximum speed has not been so materially increased, the endurance, the perfection of the mechanism, and the economy of performance have made great strides. The increased speed, which is by no means the maximum possible of a locomotive, *per se*, has been attained at much higher powers, and the schedule time has been shortened principally by cutting down grades, straightening curves, filling up ravines, abolishing trestle works, replacing wooden bridges by permanent ones of iron or stone; by the use of heavier and stiffer rails, better switches, improved methods of automatic signalling, the interlocking switch and signal system, and the abolition of grade crossing; in shops, by improvements in details and management which permit of higher speeds on more extended sections of road because of greater safety, lower traction coefficients, and a greater degree of confidence possessed by the engineer. All these things are necessary for high-speed electric railways, and any general improvements that will be of benefit to the latter must necessarily be of service to the former. Many predictions which are made concerning the future of electric propulsion, either in ignorance or disregard of the possibilities of steam duty, and the limitations necessarily existing in all systems of transportation, deserve and will receive little consideration. Hence, let us note a few of recent locomotive performances.

Almost everyone is familiar with the remarkable run recently made by a Schenectady locomotive hauling a special train on the New York Central Railroad, when the distance of 439½ miles from New York to Buffalo was made at an average speed of nearly 60 miles per hour, and which was the precursor of the Empire State Express, which makes the regular run at an average speed of over 52 miles.

More recently, we have accounts of an interesting record made by a well known writer on two runs between New York and Albany, on which a large number of indicator cards were taken. The weight of train was about 270 tons. The steam pressure varied from 160lb. to 170lb. From an inspection of about a dozen cards, the indicated horse-power varied from 551 h.p. at 41 miles to 1,120 h.p. at 78.9 miles. At 60 miles per hour the train resistance is stated to have been 15lb. per ton, and at 70 miles 17·10lb. per ton. About 7lb. of water were evaporated per pound of coal. A remarkable statement concerning this performance was made by Mr. Sinclair, which, while almost incredible, will, if borne out by an analysis of facts, prove to be something of a surprise to those who make their prophecies of the electric economies by comparative statements. In the description of these tests in a recent number of "Locomotive Engineering," it is stated that the whole trip shows an indicated horse-power per hour for an average expenditure of only about 3½lb. of coal per hour. This is far better than any stationary engines.

On the New Jersey Central Road, one schedule time is 86½ miles in 89 minutes, which is made when there are a number of necessary slackings. On the 13th of May, the time was taken of the speed of a Baldwin compound locomotive for a considerable period of time on one of the regular runs. Ten continuous miles were made in 452½ seconds, and five were made in 222 seconds. The fastest time taken was 44 seconds, and the slowest made was 47. On the 26th of last February a similar compound passenger locomotive running on the same road, broke all steam records by running a mile in 39½ seconds, or at the rate of nearly 92 miles per hour. At this speed the indicator cards showed 930 h.p., and the drivers, which are 78in. diameter, were making 395 revolutions per minute.

In the very near future I expect to have the pleasure of riding on a locomotive when going on these high speeds, and I presume my respect for steam locomotion will not be diminished thereby, nor, on the other hand, will my confidence in the possibilities of electric propulsion under the proper conditions. Experimental runs have been made with an electric locomotive at the rate of a mile in 30 seconds—that is, 120 miles an hour, and I confidently expect some day to go at that rate; but it will be under special conditions, and not on the regular trunk lines of this country, and it is the height of folly to suggest that these steam trunk lines are to be abolished. In making these very high speed runs there is not much attempt at maximum economy of coal consumption, the necessity being to generate steam as fast as required by the cylinders, but on taking an average of five trips, I find that there was evaporated 7·19lb. of water per pound of coal used, and 9·41lb. of water evaporated per pound of coal consumed. The total weight of train varied from 213 to 241 tons.

The personal equations of engineer and fireman necessarily enter seriously into steam operations, and this, compounded, of course, with the peculiarities of each engine and the conditions of service, is shown in railroad reports. In this connection, I recently inspected a number of engine sheets. On one, which gave the duty of 25 engines, the average total cost per engine mile was 10·35 cents, of which 2·66 was for fuel. The total cost varied from 6·8 to 19·24 cents, and the fuel (wood) from 1·96 to 4·77 cents. On another sheet, giving the performance of 22 engines, the total cost per engine mile was 14·70 cents, of which the fuel cost 4·61. The total cost varied from 8·82 to 27·98 cents, and the fuel cost from 2·04 to 7·43. In still another, that of the performance of 18 engines, the total cost per engine mile was 14·73 cents, of which the fuel (coal) cost 6·62 cents. The total cost varied from 10·4 to 22·52 cents, and the fuel cost from 3·82 to 13·84.

In discussing the electric system there is often a confusion of statements with reference to economy. Despite the undoubted fact that the electric motor can probably be run at variable high speeds with less variation of economy than can the steam locomotive, we must not forget that in the latter we are considering the economy of the unit on a whole, not merely of the steam-cylinders, but also of the boiler and the furnace. In electric propulsion a similar comparison of economies must take into account the variable duty of the central station and the losses on the line as well as in the motor, and where single units are used, the variation in economy of the whole system would be much greater than in the steam locomotive. There will be only a reasonable fixed efficiency of the central station and the line when the number of units is large enough to make the load on the central stations nearly constant.

Let us now consider another class of duty. Some time ago I made a very careful analysis of the work done on the elevated roads in New York City, with a view of determining the coal consumption and the duty performed by the locomotives. At the time this investigation was made, now nearly seven years ago, there were in use on the Third-avenue division, 63 trains at one time, running at very close intervals. The weight of the train was from 80 to 90 tons; the speed was often as high as 20 to 25 miles an hour; stops were made every third of a mile; in short, the duty demanded of the engines was exceedingly severe. The maximum indicated horse-power of the locomotives was found to average about 163 h.p., although on occasions these locomotives have been worked up to 185 h.p. Work was divided approximately as follows: Acceleration in starting, 59 per cent.; lifting, 24·3 per cent.; and traction, 16·7 per cent. The average horse-power exerted was 70·3 h.p., considerably less than one-half of the maximum. The work on the line was so distributed that there was an almost constant total duty duty of about 4,500 h.p. The locomotives were on duty 20 hours, but used steam only six hours, and, including all losses when standing still and the amount of steam used in braking, there was a horse-power developed for about 6·2lb. of coal per hour. I believe that these

figures are entirely reliable, and they show a remarkable performance, when we consider the class of duty. An analysis of the coal expenditure showed that, with an efficiency of 60 per cent., and without any of the energy of the train being returned to the line, the relative coal expenditure between steam and electricity would be about in a ratio of 2 to 1; but if the energy of the train was returned to the line, to the extent which I believe it is possible, then the relative expenditure of fuel would be in the proportion of 7 to 2. Since the coal charge on the four divisions was at the time about 550,000dols., it can easily be seen that, independent of any question of saving, in the care of the structure and any reduction of depreciation of the motor equipment, the fuel saving would be sufficient to pay a good interest on the cost of an electric equipment; and a large interest on the cost of electrical equipment minus this value of the present engines. I have no reason to doubt the soundness of the conclusions I then made. You will have here in Chicago, however, a somewhat more advanced condition of affairs. A compound type of locomotives has been adopted for the elevated road service, and I believe it will show an increased economy over that of the operation of the New York roads. Consequently, in discussing the question of economy, it is necessary to get full information concerning the duty which will be done here.

In discussing high speed possibilities and limitations, the testimony of Dr. Dudley, as given in a discussion of a paper before this institution on the 24th of February, 1891, is interesting. There are, generally speaking, three distinct elements constituting the resistance to train movement on a level, and they have a most important bearing, when we consider the operation of long or short trains, and at high speeds. One of these elements is the friction of the train in its bearings; with good rolling-stock, this is about 3lb. per ton. For all reasonable speeds it is probably fairly constant, provided the lubrication is good. Another element is that of air resistance, which varies with the shape of the forward end of the train, the condition of the air, the direction of the wind, and the velocity of the movement. The third I may call the train lifting or rail bending effort, which depends upon the weight and stiffness of the rails and solidity of the road-bed. Dr. Dudley stated that on the New York Central system he found that trains of about 250 tons when running at a speed of a mile a minute have a resistance of from 10lb. to 12lb. per ton; but that on short trains of but two or three cars, the resistance sometimes ran as high as 35lb. or 40lb. per ton. This is probably due not to any change in the friction of the bearings, but to the fact that the air resistance enters as a much higher component of the total. It at once emphasises the fact that the operation of short trains must, at high speeds, no matter how good the track, or how favourable the circumstances, be with a train resistance higher than that required by long and well vestibuled trains. Such a shape can be given to the front of an electric locomotive as will make the air resistance not over one-half that presented by a plane surface or equal cross-section, and perpendicular to the line of motion, but even this fact does not alter the other, that the resistance per ton must be higher for small trains than for large ones.

Dr. Dudley further stated, in speaking of the influence of stiff rails, that the difference in power required on the Chicago limited when running on a 80lb. and 65lb. rail was from 75 h.p. to 100 h.p. per mile—that is, somewhere between 10 to 12 per cent. of the power actually developed—and he estimates that with a 105lb. rail, which is nearly twice as stiff as the 80lb. rail, there would probably be saved another 100 h.p. per mile, making a total saving of a quarter by less than doubling the weight of the rail. In this opinion it is perfectly safe to run a steam engine 120 miles an hour on this heavy rail. Such rail improvements increase speed possibilities with present engines, but we have not related the limit of steam duty.

Almost all the locomotive work of the United States has been done up to the present with simple engines. Their weight and capacity has been increased, their steam pressure raised until the standard is now about 140lb. Within recent years, however, the compound locomotive has come into use, and there is a comparatively large number of them in daily service. The steam pressure has gone up to 180lb. as a standard, working sometimes as high as 200lb., but these are by no means the limits of steam pressure. On the Paris, Lyons, and Mediterranean Railway, the standard for steam pressure for compound locomotives is 250lb. The compound locomotive has still its battle to fight, but I think it would be a rash man who will say that the days of still higher steam pressure are not to come, and that the triple-expansion locomotive will never exist.

Speed, capacity, and coal economy are, however, not the only questions to be considered in railroad operation, and in discussing the general subject it will be found that the signalling and braking questions at high speeds are serious ones. Undoubtedly, an electric train with distributed motors, making the weight of the train available for traction, could, by using the motors as dynamos to return the energy of the train to the line from the highest to mean speeds, and then on a local circuit, be more quickly and effectually slowed down and stopped than where shoe brakes are used, and both methods, of course, would be available But if using a motor ahead of a train, then there will be comparatively little difference in the stopping power. When riding at 60 or 70 miles an hour, it is a very quick stop to bring a train at rest in less than 2,000ft. This is often as far as any signal can be made out, especially when the weather is at all thick. Hence we may expect to find on electric railroads, if high speeds are to be attained, and quite possibly also on steam railroads, an extension of automatic signalling so that trains indicate on more than two sets of signals. At present the practice is to divide the line into sections, and when a train passes a certain point it sets a danger and cautionary signal, dropping the danger signal on the section just preceding, and the cautionary signal on the one beyond.

Turning now to the greater powers, we must not confuse the terms "large powered" and "trunk line" work. There are two statements which I think will need no corroboration. If we had a continuous train movement completely occupying a track system, there can be no question but that its operation from a central source by electricity would be more economical than if operated by steam locomotives. So, too, if a large number of units in reasonable proximity are moved, and the stopping and starting so regulated that the total demand upon the central stations is fairly continuous and equal, then there is no question as to the economy of electric propulsion as compared with steam. On the other hand, the operation of a single or very few units over a long distance would be so uneconomical and afford so small a return on the investment required as to make it prohibitory. Between these two lines the condition of operation where steam and electricity meet on planes of equality; as the number of trains decreases, steam operation is the more economical; as the number increases, electricity must be preferred.

In discussing the use of electricity instead of steam, a well-known steam engineer recently stated that in his judgment it might be conceded that E.M.F. for the propulsion of cars will not be economical, except for suburban traffic, and upon certain sections of important trunk lines like New York Central between New York and Albany, the Pennsylvania system between New York and Philadelphia, and other lines of like character where it is necessary to dispatch a large number of comparatively light trains every day, and at short intervals. The principal field for a power of this kind would be in suburban service long enough to make the ordinary street electric car unpopular because of the time required, and in such cases as these mentioned above, also for moving freight trains in city; that is, for the performance of transfer service. That is precisely in line with the arguments which I have advanced from time to time, and which I illustrated in a paper before the National Electric Light Association and its convention in Kansas City, where I outlined the possible service between New York and Philadelphia, which I believe to be practicable, and to which I will again refer I must repeat that it narrows itself then to the one question as to the number of trains operated between two terminal points. Make that number of trains sufficiently large, and the electric motor is the best means of propulsion whether for high or low speed, whether for large or

for small cars. Decrease this number and we must rely on steam propulsion, or to put it in another way, the answer to the query, will electricity take the place of steam for railroad purposes is, only in part, and then only when the number of trains operated between the terminal points is so large that the fuel economy would pay a reasonable interest and depreciation of the necessary cost of the central station and the system of conductors Of course, I do not in this general reply consider those special cases where advantages are to be gained for which there is a return for capital in another direction. Such a case is that of the Baltimore tunnel, where the investment and cost of operation will be greater than that for steam propulsion; in fact, there will practically be no economy in power, because the steam locomotives are not done away with, but simply unused for a period of a little over a mile. There is in this specific case, however, the incidental advantage of doing away with the necessity of a ventilating plan, and yet getting rid of the annoyances incidental to tunnel services.

Trunk line transportations being a great problem, we should not attempt the simultaneous solution of all the questions involved, but instead, determine what those questions are, consider their sequence, and the probability of success, and solve them in their order. Every system has its limitation. The electric is not exempt from this law, and hence it will set forth what are well-known limitating laws concerning the transmission of energy. They have been stated time and again, but somehow or another, people often lose sight of them in discussing the question of investments in large electric railways, so that I think it will be well perhaps to restate and emphasise them. The weight of copper necessary to transmit a given amount of power with a fixed loss will vary inversely as the square of the E.M.F. used. The distance to which it can be transmitted with a given weight of conductor will vary directly as the pressure. The distance to which it can be transmitted over a conductor with a given cross section will vary directly as the pressure. The weight of copper necessary where the supply station is in the centre of a system is only one-quarter that required if the station is at one end. The weight of copper will vary inversely as the square of the number of supplying stations properly placed. The E.M.F. required will vary inversely as the number of stations. Lack of knowledge of these simple and unalterable laws has led to much misconception of electrical possibilities, and these have not been confined to the electrical engineer.

In many of the suggestions which have been made, even by practical steam engineers, there has been an unnecessary confusion of impracticable and practicable, and the specific object which should have been borne in mind has been lost sight of Committees have drawn impossible specifications for trunk line service, and demanded of electric motors a capacity and performance superior to that of the best compound steam locomotives. I unhesitatingly pronounce any attempt to build some such machines for the present certainly unnecessary and impracticable. The service thus suggested, if at all needed, will for many years be better performed by the steam locomotive than the electric.

Leaving out of present consideration trunk line work, there are three problems requiring solution in the application of electricity to propulsion on a large scale under conditions existing, for example, in Chicago, or in any other place where there is a movement of a large number of trains on more or less complicated tracks as will be found at almost all terminal railway stations They are.

1. The development of an electric locomotive of ample power, which shall be as readily controlled as the steam locomotive, shall be reliable in operation, and shall show a high economy. Of course, such a machine must have all the adjuncts which are necessary for train movement.

2 A system of conductors and methods of supporting the same which can be relied upon for ample supply of current and absolute certainty of continuous contact at all speeds on curves, switches, cross overs, and the multitudinous combinations which exist on yard tracks.

3. A system of automatic block signalling, which, while effective for steam traffic, will not be thrown out of operation by the use of tracks as conductors of electricity for a general supply This is a more serious question than is at first considered, for this use will materially interfere with, if not absolutely destroy, the utility of what is known as the rail circuit system. This third problem is one which must necessarily follow the development of the other two, as the automatic signalling systems now existing have followed the development of steam practice.

While I am not by any means thoroughly familiar with the various methods of automatic signalling, I believe I am justified in saying that there is none at present existing which will meet all the requirements of railway practice, and which can be operated on track used by both steam and electric locomotive, where the rail is used as a part of the supply circuit. Some of the best-known systems of signalling would be rendered entirely inoperative. As difficult as it may seem to devise such a system, I believe that it certainly can be developed, but only properly so on a section of track which is more or less experimental, on which, at the time of operation, automatic signalling is unnecessary, but which is actually operated by both classes of service. Such an experimental section would be a combination of single and double tracks, with all the varieties of curves, crossings, switches, and ladders, such as would be found in any large yard. It will probably be found necessary to erect a variety of kinds of conductors. From the most careful consideration which I have been able to give to the subject, I believe there is one way, and only one way, in which the current can properly be supplied in any complicated system, and that is from the overhead conductor, practically rigid in character, following very nearly the centre line of all tracks and switches, with no movable overhead parts, and with return through the rail. The locomotive would then practically be moving between two electric planes, the lower being the guiding one.

I know there has been a great deal of talk about other possible systems of supply. We have heard much of the charged rail using low-potential currents, supplied at frequent intervals by motor-generators driven from a central station. Since we have discovered no conductors devoid of resistance, and the art of welding is not particularly applicable for railway service, where moving contacts are a necessity, little credence need be given to any scheme of this character. We heard again of the central rails, supported on posts, in wells between the tracks. A centre rail may be acceptable on a system like that of the elevated roads, but in ordinary railroad work any ditch intended to drain a track, so as to keep insulators dry and keep snow away from them, would probably so open the track that any moisture and frost would cause upheavals of serious character, and the cost of maintaining the track would be prohibitory. The use of snow machinery for keeping the track clear would be impossible, and anything underneath the car is in the most exposed place for sustaining damage by defective rolling-stock, and continually liable to all sorts of mechanical injuries and accidents, with all the evil results of interruption of current, short-circuiting, and stoppage of traffic.

Another system which has been proposed is that of a conductor supported on posts alongside of the track, and elevated but 3ft. or 4ft. above it. While not open to so serious objections in the matter of insulation as a centre rail system, its use where there are crossings or switches is manifestly not to be thought of. Even on a straight clear track in a hard climate there would be most serious trouble in the matter of clearing the tracks from snow, and with the grade crossings in this country gaps in the conductors would be too great for the contacts on a single locomotive to stand. Some time ago I was requested on behalf of a well-known financial man, whose enthusiasm as to the possibilities of electric traction is well known, but who is withal a most practical railroad man, to inspect various railroad terminal tracks in this city with a view of, first, the substitution of the switching work now done by a part or all of the 1,800 or more switch engines by electric motors, and eventually the operation of suburban service. In Chicago, in the space of about two square miles or more, exactly 1½ miles in length by threequarters of a mile in breadth, it is no exaggeration to say that there is or will be not less than 75 miles of track, and switches and cross

ings with their various combinations almost innumerable. I went over and over some of these tracks with the one thought in my mind, how can the current be delivered to the locomotives, and how can the automatic signalling be done? And I was forced to the one conclusion to which it seems every man who makes the investigation must come, and that is that the overhead system of supply is the only one, but that it must be as substantial and thorough in character as that of any other part of the system; and, further, that in view of the cost, such a system is only permissible where the number of units operated is large and continuous. These conclusions are not new, but they have been emphasised by the particular problem which is here represented.

Intimately connected with the question of conductors, and one of the most serious ones which has to be met by the electrician, is that of potential. The personal danger limit of continuous or ordinary period alternate currents, is pretty well determined, and it seems generally admitted by constructors that the danger limit for a continuous-current machine, with its commutator, is about the same as the personal danger limit. Hence we meet with two dilemmas. If using continuous-current motors, we are limited to a difference of potential per machine of 1,000 to 1,200 volts, and we can, so far as safety of the machine is concerned, only probably go above this limit by putting the motors in series, precisely as has been proposed for long-distance stationary transmissions. If this is not done, then we have the introduction between the transmitting dynamo and the receiving motor of a motor-generator system—another pet theory which is often suggested, but which I unhesitatingly pronounce as so uneconomical as to be impracticable. If using an alternate-current system, the converters must be used, either distributed along the line and supplying the working circuit or placed upon the locomotive to safeguard the motors. While the use of a converter under these conditions is not as objectionable as the use of the motor-generator, it cannot commend itself as a very practicable scheme, and certainly in view of the fact that no single phase single alternate motor promises, up to the present, serious success. For the present, and I think for a long time to come, we must confine ourselves to the consideration of railroad problems where continuous currents are used, and where the traffic between two points is sufficiently large to justify the investment in central stations and conductors which would be required for the operation of such a system.

There are two methods of propelling trains electrically, one by following steam practice—that is, by building a large motor, and hooking it to the head of a train—the weight of the motor being such as is required for the necessary power and traction when grades or slippery tracks are encountered. From all that has been developed up to the present, to get the control that is necessary, and to build the machines safely, the electric locomotive will weigh nearly as much per horse power as the steam locomotive. This weight can be better distributed, but I do not think if steam practice is followed on trunk line service that there could be any very material reduction of weight of train. The other plan is to have each car propelled by one or more motors. This would be the ideal system so far as propulsion goes, provided the electric motor was unlike all other mechanical apparatus and that it never failed, and if a number of machines could be as well taken care of, cost no more, and show as little depreciation as fewer machines of larger capacity operated as a unit.

Should we ever arrive, as we all hope, to the possession of a single-circuit alternate-current motor, then, in view of the simplicity of its control, we may fairly hope for the distributed-motor system. But here also, the capacity and likewise the weight of the motor being determined by the total duty done, the weight of train limit would not be decreased, but rather increased. If, on the other hand, single units are used, the query naturally arises, What form would the electric locomotive of the future take? I do not think this is by any means settled; undoubtedly, gearless machines will be used, but whether they will be mounted directly upon the axle, or whether they will movably enclose the axle and be flexibly connected to it, while their weight is carried on springs on the truck, or whether the motor will be carried on the truck frame and connected to the drivers by the ordinary coupling rods, are questions which will be determined eventually by the depreciation per car mile upon the motors, trucks, and road bed, as well as by the speed to be attained. Whatever method of mounting the motor is adopted, for reasonable weights and powers a two-axle truck will be used, but where the large powers and weights are necessary, two such trucks will be coupled together, so as to keep the weight upon each wheel within limits, and this will carry a cab containing the regulating and collecting devices, and so shaped as to offer the least resistance to air pressure and high speeds. I have never advocated the use of a connecting rod in transmitting the motion from an armature to a driving axle, but I think it fair to say, in this respect, that the so-called hammering effect on the rails, said to take place in the ordinary locomotive driver, where the weights are counterbalanced, exists more in imagination than in fact, and that the chief trouble in the use of the connecting-rod is the change of direction of its movement.

Among the roads which are ripe for the electrical engineer, and on which in the near future I hope he will demonstrate he has a most legitimate claim, are the New York elevated and Chicago elevated, the handling of the trains on the New York Central and Harlem roads below the Harlem River, the long talked of rapid transit road of New York, the Metropolitan underground road of London, the proposed tunnel roads of London, Paris, and Berlin, and, coming more immediately home, suburban service such as that of the Illinois Central Railroad, a most ideal track for the electrical engineer; and last, and, as it will prove, one of the most important, the operation of terminal and warehouse systems for the interchange of freight on the lines entering a city situated as is Chicago. Taking this last, we have here a definite problem, now performed in a more or less satisfactory way by steam service. It is a problem large enough of itself. It has little connection with electric trunk line service, and the present impracticability of the latter has little bearing upon the thorough practicability of the former. Eighteen hundred or more switch engines, many of them on duty 24 hours a day, a large portion of the time standing idle, puff their foulness into your overburdened atmosphere, because from 80 to 90 per cent. of all the freight that comes into the depôts of this city ought never come inside its limits, and would not were there a practical way provided to distribute it from one railroad to another outside the city limits. It has been suggested, and it seems to me a most feasible plan, that there shall be established a vast system for interchanging freight on the various railroads by a great six-track crossing belt road which shall form a common zone of transfer either by itself or in combination with freight warehouses or storage yards. Undoubtedly there are many difficulties in the way, but from an electrical standpoint there is absolutely no question but that such a system of belt line is practicable. With such unsolved problems, such abundant fields, I deem it unnecessary to attempt to build electric locomotives to pull trains of great weight 100 miles an hour, or to develop a system of conductors for trunk line service which is not possible for yard duty, or to consider a central station or track equipment for a duty not required. This problem is in a measure an experimental one, which being carried to a certain measure of success will clearly point the way for future development and outline its limits.

I may be pardoned perhaps if I take radical views in some matters of railroad practice. I have fortunately or otherwise been thrown into direct touch with all the larger work which is to be done in this country during the coming year, and it gives me pleasure to announce what many of you know from the current news of the day, that there will probably be in operation in the United States within 12 months not less than five locomotives varying from 700 h p. to 1,200 h.p. and from 45 to 80 tons in weight. The character of the work done will vary. In that work in which I am most concerned from a personal standpoint, a 700-h.p. electric locomotive will be built for experimental work, and to attempt to solve as far as may be the various problems which are involved in railroad practice

in Chicago. If my judgment is followed, there will be an experimental section of track in the form of a loop about 13 miles long with 18 miles of rail, and with every variety of single and double track construction and simple and compound crossings and switches. On this I hope to see erected such varieties of overhead construction as may be found best to meet the various kinds of service, and where the railroad problems on track jointly operated by steam and electricity can be developed in the most satisfactory manner. On this track there will be not only this locomotive but also one of equal rated capacity supplied by one of the larger manufacturing companies. The duty demanded of these machines will be severe. They will be required to haul a train of not less than 450 tons at 30 miles an hour up a grade of 26ft. to a mile. They will probably be required to develop their full rate of capacity at all speeds between 30 and 60 miles per hour, and if there is sufficient track room they will be driven at speeds of at least 75 and perhaps 100 miles per hour for short distances. The potentials used will be nearly double that at present obtaining in street railway practice

A still larger problem so far as power goes, although not in the variety of conditions which will have to be met, will be that recently taken for the operation of the belt line tunnel now being constructed in Baltimore to avoid the necessity of boat transfer to Locus Point. The duty of the motor here will be to propel the trains with engines coupled on but not in operation through a tunnel about 6,000ft. long. The conditions require the motors, which will weigh about 60 tons, and have a capacity of about 1,200 h.p., to propel a 1,200-ton freight train up a grade of 42ft. to the mile at a speed of 15 miles. Passenger trains of 450 tons weight must be regularly started from rest twice in the tunnel on this grade, and in an emergency the motors must start the freight train. The draw-bar pull under regular duty, and when not starting, may be as high as 32,000lb. Perhaps the traffic from New York to Philadelphia affords as good an example as any of what may be done on regular passenger service, provided the track is clear enough. For this I some three years ago outlined a service and again in the Forum of September, 1891, an electric express service with a method of supply through a rod carried above the car and a return circuit through the rails and earth. The current was to be supplied from one or more central stations equipped with high-class triple-expansion engines driving multipolar dynamos directly coupled. What the electric engineer, and the railroad man as well, needs to know is whether the E.M.F. required on the line and the number of stations necessary would be prohibitory. No attempt was made at excessive speed, but I confined myself to the average speed of a mile a minute for a distance of 90 miles, and considered a through service only. I assume a total weight of copper of only about two-thirds that which existed on the long-distance telephone line between New York and Boston. The trains were to be two car units leaving every 10 minutes. I found, with these conditions, the stations and potentials would be about as shown in the following table:

Stations.	Miles apart.	Potentials. Two-wire.	Three-wire.
1	—	3,600	1,800
2	45	1,800	900
3	30	1,200	600
4	22½	900	450

If the three-wire system is used—that is, the rails as a compensating conductor, between two trolley rods—then with only two stations 45 miles apart, it is seen that the potential is less than 1,000 volts, and this we undoubtedly can handle. I am not prepared to say that we may not use even a higher pressure, because I believe whatever is demanded in the interests of economy, all things being considered, will be used, but if we can reduce the potential to perfectly safe and reasonable limits by multiplying the number of stations, then these stations should be increased so long as the increase does not seriously affect the general expense of working. On a service of this character, where I have made the conditions distributed work, and the dispatching of units at brief intervals, which conditions, I repeat, are absolutely necessary, if we are to consider long-distance transportation by electricity, such increase of stations as is advisable will not increase the cost of central station operation.

Such is the work before you—a work well meriting your best efforts, yet is well to temper your enthusiasm with prudence. Limit your attempts to the solution of those problems which will prove of practical benefit. Do not chase rainbows. They are beautiful and poetic, but they have small place in the world's economies. Remember that neither sentiment nor ignorance are winning cards, but lessened cost of operation for equivalent duty and increased returns on invested capital. All this is said in no spirit of discouragement, for I yield to no man in my confidence in the future of electric traction. No new field is so rich, none more pregnant with great possibilities, but the growth of the work will be more expeditious and healthy if we separate the visionary from the real, the impracticable from the practicable.

WATERFORD.

At the meeting of the Corporation last week the town clerk read the following report of the Lighting Committee:

Having had an interview with the committee of the Harbour Board, we are now in a position to report finally on the question of the public lighting of the city. We give below the relative cost of each system of lighting, and beg to submit to the Council for its approval the annexed resolutions, which we have agreed upon as being fair and reasonable to all parties. It will be seen by the figures submitted that the cost of lighting the city by electricity and gas will be £120 per annum in excess of lighting by gas alone, and £210 per annum in excess of electricity and oil, and that the cost of lighting the whole city by gas will be £90 per annum in excess of electricity and oil. We may mention that the Harbour Board contribution in future will be £120 per annum, conditionally on the continuance of the same number of arc lamps as at present, that Board undertaking the lighting of the hulks themselves by gas.

SUMMARY OF PUBLIC LIGHTING.

	£	s.	d.
Gas.			
394 lamps, at £2. 15s.	£1,083	10	1
Extra on large lamps	112	10	0
Clock tower	10	0	0
Sallypark Corporation contribution	7	10	0
	£1,213	10	0
Electricity and Gas.			
34 arc lamps, at £24	816	0	0
210 gas lamps, at £3	630	0	0
Sallypark Corporation contribution	7	10	0
	1,453	10	0
Harbour Board contribution	120	0	0
	£1,333	10	0
Electricity and Oil.			
34 arc lamps at £24	816	0	0
210 oil lamps, at £2	420	0	0
Sallypark Corporation contribution	7	10	0
	1,243	10	0
Harbour Board contribution	120	0	0
	£1,123	10	0

"Resolved,—That we are prepared to offer the electric lighting company £24 a lamp for five years for the public lighting of the city, and that we are also prepared to assign to them our powers under the provisional order for a term of 10 years, on condition that it be within the power of the Corporation to purchase from them at a valuation based on an arbitration, one arbitrator to be appointed by the Corporation, one by the electric lighting company, and in case of disagreement, an umpire to be called in, with the proviso that should the Corporation be not in a position to so purchase from the company, they will be prepared to grant them a further term of 10 years of their provisional order, they (the company) providing all necessary expenditure for cabling and wiring the city. That, further, we offer the gas company £3 per lamp for five years for the public lighting of that part of the city at present lighted by oil. That, in case the electric lighting company refuse our terms, we ask the Council for permission to make immediate arrangements with the gas company to light the entire city by gas at their tender of £2. 15s. a lamp, with the addition of the large lamps as required."

After considerable discussion the report was adopted.

Atlantic Lines.—The Directors of the Atlantic First Leased Lines Rental Trust, Limited, have declared an interim dividend of 2½ per cent. for the half-year ending July 31, payable on August

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

CHICAGO EXHIBITION.

The London Chamber of Commerce, as well as other local Chambers, is taking considerable interest in the Chicago Exhibition. At the meeting of the Electrical Section the other day, energetic, but not manufacturing, members urged, to the electrical industry, the general participation in this exhibition. We have received from the London Chamber of Commerce a list of thirteen exhibitors who have applied for a total of 4,739 square feet of floor space. No sketch of the imagination could represent these thirteen exhibitors as representative of the English industry. Two or three stand in the front rank, the remainder are more or less in the category of exploiters, and to them Chicago is as much a field of operation as is London. The time has long since gone when even international exhibitions were looked upon as anything other than business concerns. There might have been pride of initiation and sentimental feelings in 1851, but now exhibitors do not exhibit from patriotism, but with a view to obtain custom. It matters nothing how the custom comes, direct or indirect, and ofttimes the indirect effects are far more valuable than the direct. "We have not cleared our expenses" is the cry too often heard. That is not the question. Has the general volume of business increased? If it has, it is but just to attribute the whole or a part of the increase to the taking part in exhibitions. Thus the direct orders taken at the late Crystal Palace Exhibition may not have paid the exhibitors—but the balance-sheet of that exhibition cannot be closed for months, if for years. The seed sown will bear fruit, and the installation of some town in '93 may really be due to the exhibit of '92. Partners and managers are not slow to realise all this, and no doubt have thoroughly examined into the possibilities of the Chicago Exhibition. Their hesitation to apply for space seems to indicate a conclusion adverse either to direct or indirect business. So far as the Chicago Exhibition is concerned, the business part of the matter seems exceedingly simple. Our engine-makers and our dynamo-makers, except in the case of those owning patents in the States, can hardly hope to open up business in the States. We may be able to sell a dynamo here and there, but nothing like an extensive business in this direction can be forthcoming. In the thousand and one accessories to electrical work in lighting, traction, telegraphy, and telephony, agencies may be opened and sales effected. So far, then, as the States are concerned, we may put on one side any wide prospect of increasing our engineering business. A more important question, however, is, how will this exhibition affect electrical enterprise in our colonies and in other countries outside the States from China to Patagonia. Will likely buyers wend their way to the exhibition from all these quarters? Take Australia, and confine the consideration to electrical apparatus. Almost all our large makers have agencies in Australia, many have installations at work, and they must decide whether many purchasers are likely to be lost by visiting Chicago and seeing competitors' manufactures. There can be no doubt but that thousands of visitors from our own

colonies and from South America and Asiatic districts will visit this exhibition; only a portion of those visitors, however, will be interested in electrical matters. It is this question of colonial business that has induced some of the thirteen to apply for space, and it may be that others who have hitherto held back have not sufficiently considered this point in the problem. The discussion at the London Chamber of Commerce brings it before them, and it is not too late to change their views. The argument that these exhibitions mean our giving to rivals the secrets of our practice and making them a present of our designs, is pure and unadulterated rubbish. If a rival wants to know all about a machine, he will buy one and study it in detail in his own works. He does not expect to gain much information at exhibitions. Of course the man who is so cocksure that everything he does is infinitely superior to anything anybody else does, can never be made to understand that he is really very much like other men, only perhaps more so—having as much to learn as to impart. We are thoroughly of the opinion that if it is worth while exhibiting at Chicago at all, it is worth while doing it well. A few paltry exhibits are neither indicative nor representative of the industry, and give visitors no idea of what they may expect to find in this country. Our intention is not to decide for or against, but to point out a few of the facts which must be carefully considered before coming to a final decision. One thing is certain, the expense is great. If, on the other hand, the return is commensurate, go ahead.

FOREIGN COMPETITION.

A very comprehensive subject was just touched upon at the Electrical Trades Section of the London Chamber of Commerce last Friday, in the shape of the idea expressed by the title of this article—that bugbear of British manufacturers, from makers of tintacks to shipbuilders—foreign competition. The problem was brought forward by Mr. Edmunds, who, however, was prevented from being present to expound his views, so that we may expect a further development in the future when the section meets again in October. Seeing the question was raised although but tentatively, it may, perhaps, be well to dwell for a moment on what must tend to become a more and more pressing problem. When we are told that English electrical manufacturers can produce the best goods in the world we may be inclined to agree, but there are other factors to come in besides quality; and these are cheapness and push. We must leave the discussion of cheapness for the present. As processes tend to improve the cost of production alters, and the effect of the higher price of labour is as often to lower the cost of actual production as not—witness the products of the United States. The item denominated "push" is perhaps the principal one in leading and keeping the markets of the world; and English manufacturers are at present—now home wants are becoming rapidly supplied—turning to foreign and colonial markets. What we find here is that American and German, not to mention Belgian, manufacturers are running, not only close, but often far ahead in the supply of electrical requirements. The industry has been in a curiously international state up to the present, and American, German, and English manufacturers have jostled side by side for abiding place on British soil. The industry has now settled down to steady work, and the problem is the competition, not of systems of this or that country, but of the companies and firms of this or that country—quite a different affair, and that which is meant when speaking of foreign competition.

We see, in looking around, the steady progress of American engineers in fields hitherto covered by British manufacturers. Australia is well canvassed by the great companies of the States, who can do this the more easily as the recent amalgamations have concentrated their forces. In Europe, Hamburg has recently purchased a hundred thousand dollars' worth of American cable; Brussels, itself a busy engineering centre, has succumbed to the wiles and the skill of Thomson-Houston as regards its tramways, though here Britain may score a success in the electric light station. German firms are doing an immense trade, home and foreign, and with large central works at Berlin have branches in various departments in all parts of Germany, in Switzerland, Brussels, and London. Their technical colleges are the best equipped that money can procure. The students are trained not only in technics, drawing, engineering, practice and theory, but in commercial proceedings, and in languages. Hardly any well-educated German student but knows French and English well, besides his own tongue, as well as being trained in the art of playing into each other's hands. They recognise the value of foreign markets, and know how to set to work to acquire them often before the insular Briton has awakened from the short-sighted policy of waiting for orders from home. Circulars in various languages, properly-equipped travellers, and a good use of the foreign State consuls—these are all part of the organisation that must be used to secure the foreign and colonial market. Britain is a mere sixpenny piece on the map of Europe, without her Imperial possessions, and the great and immediate advantage of keeping in personal touch with Imperial Britain has been abundantly shown by the result to Messrs. Crompton for their enterprise in sending one of their directors a business tour around the globe. We in England are often too frightened at a voyage. To go to Paris, or even to Dublin or Edinburgh, is quite an undertaking, while how many engineering firms would send off an engineer on the spur of the moment to Vienna, Malta, Gibraltar, Ceylon, or Calcutta when a prospective engineering order is on the cards? Yet American firms think nothing of two or three days' or a week's journey about the States, or a month in Europe. The fact is, that most people in England have not yet realised the extent of the world, the necessity for learning the spoken foreign languages, or the fact that British consuls exist all over the world for the main purpose of affording a means of information to aid British trade. It is time the Chamber

of Commerce did take the question up as far as they can do so. We hear as we write that an order for four hundred twelve-ampere arc lamps and dynamos to match has just been given from Manchester itself to a Belgian electrical engineering firm. Here is a fitting item to emphasise the contention of Mr. Edmunds, that foreign competition is a matter of vital interest to the British trades and is worth a little serious attention.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WESTINGHOUSE TRANSFORMERS.

SIR,—Referring to the report of Dr. Hopkinson on our transformers (copies of which have been sent to you), we have just received an intimation from Dr. Hopkinson that an error has occurred in the last paragraph but one—namely, the efficiency of the transformer at quarter load should read "over 92 per cent.," instead of "84·7 per cent."

We should feel much obliged if you would kindly refer to this in your next issue.—Yours, etc.,

ARTHUR E. SCANKS, Secretary.

Westinghouse Electric Company, Limited,
4, Victoria mansions, 32, Victoria-street, E.C.

DEATH OF MR. CYRUS FIELD.

We regret that since our last issue Cyrus Field has passed into the great unknown. Born in 1819, he had reached the ordinary span of life. He died on Tuesday last. As we said in our leader last week, he was the real initiator of Atlantic cable enterprise—an enterprise the success of which has revolutionised the business transactions of the world. Cyrus Field had made a competency and retired from business when, at the instigation of F. N. Gisbourne, in 1854, he became interested in cable work. Few men have left deeper "footprints in the sands of time" than he of whom we write.

CYRUS FIELD.

THE SUCCESSFUL PIONEER OF SUBMARINE TELEGRAPHY.

To the Editor of THE ELECTRICAL ENGINEER.

SIR,—As one of the many thousands of admirers of the late Mr. Cyrus Field, I read your expressive article which appeared in last week's issue relative to this remarkable man with interest, and I feel sure that every electrician and telegraphic operator will receive with profound regret the sad intelligence of his decease, which this week has been wired over the same ocean in which his pioneer work was commenced. This eminent personage may truly be called the founder and father of successful submarine telegraphy. Although it is said that the idea of conveying flashes of lightning may have been inspired by the writer of the Book of Psalms (for in chap. xix., 4, it is stated "Their line is gone out through all the earth, and their words to the end of the world," which words clearly show that even at that remote period there existed crude ideas respecting the future utilisation of the subtle fluid and ethereal energy called "electricity," which combination of matter and force was first christened by this name in the year 1600 by the late Dr. Gilbert, of Colchester), yet from published reports it is evident that the germ of the modern idea of its utilisation and application for purposes of submarine telegraphy is due to and emanated from Mr. F. N. Gisbourne, of Montreal, and Mr. W. F. Armstrong, of New York, whose suggestions were practically brought to a successful issue under the guidance and perseverance of Mr. Cyrus West Field, and the assistance of his co-workers in the enterprise, which included the late Sir Charles Bright, Mr. Whitehouse, Mr. J. W. Brett, and the present Lord Kelvin (then known as Prof. Thomson).

It has often been said that the true character of a man may be judged by "phrenology," also by his conversation and speech. Now, if the latter be true, then I venture to say that some of Mr. Field's sterling qualities may be judged by a perusal of the pretty little speech he delivered at the inauguration of the landing of the first Atlantic cable in Valentia Bay, which, according to history, took place on Wednesday, August 5th, 1857. And, in reply to a request of the Earl of Carlisle, the then Lord-Lieutenant of Ireland, and an influential assemblage, Mr. Field said, "I have no words to express the feelings which fill my heart to-night. It beats with love and affection for every man, woman, and child who hears me (cheers). I may say, however, that if ever at the other side of the waters now before us, anyone of you shall present yourselves at my door and say that you took hand or part, even by an approving smile, in our work here to-day, you shall have a true American welcome. I cannot bind myself to more, and shall merely say 'What God hath joined together let no man put asunder,'" words which I think clearly show the character of this remarkable man.

As many of your readers may not be acquainted with the personal history of the eminent personage who has done so much for the world at large, I would briefly state that Mr. Field was born in the town of Stockbridge, in the State of Massachusetts, in November, 1819. His father was the Rev. D. D. Field, a graduate of Yale College, and the late Mr. Field was one of seven sons, all of whom have held distinguished positions in the United States. One brother, the Hon. D. D. Field, of New York, is well known on both sides of the Atlantic as one of the revisers of the code of the State of New York. Another, M. D. Field, was a leading citizen of Massachusetts, and for some time a senator. His brother Jonathan Edward Field was at one time a judge in the Supreme Court of California—the judge who has recently tried several important infringement cases in the United States in connection with electrical science. In early life, it appears that Mr. Cyrus West Field—better known as simply Cyrus Field—occupied a position as clerk in the well-known drapery establishment of A. T. Stewart, of New York. Prior to his taking up the science of telegraphy, which commenced in the year 1854, he had previously founded a large paper manufactory in Massachusetts and a commission merchant's warehouse in New York, and by his association with Prof. Morse became initiated into the merits of telegraphy, and thus took a great deal of interest in the advancement of the same. His pioneer efforts were in connection with the formation of the New York, Newfoundland, and London Telegraph Company, which afterwards by his splendid organisation, patient perseverance, and indefatigable energy, was converted into the Atlantic Telegraph Company. The success of this company, although after many attempts to overcome failures, is now well known throughout the entire world as one of the greatest events of the present century, and Mr. Field's work in connection therewith has been the means of linking nations in the bonds of union and finding employment for thousands. Hence I crave a small space in your journal to record a brief account of the grand work pioneered by the above, which work has rendered such service to mankind, not only to signal important events of the day, but also to flash the transmission of thought in all known languages from one part of the globe to the other.

For the past 15 years Mr. Field was prominently connected with the New York Elevated Railway, the success of which is also greatly due to his tact and assistance; and, therefore, with two such gigantic and marvellous successes, his name cannot fail to be handed down to posterity as one of the foremost pioneers of the present century.—Yours obediently,

July 13th. ARTHUR SHIPPEY.

LONDON CHAMBER OF COMMERCE.

A meeting of the Electrical Trades Section of the London Chamber of Commerce was held on Friday last at the offices, Botolph House, Eastcheap.

The SECRETARY read the minutes, which referred more particularly to the appointment of a special electric traction committee and the deputation to the Board of Trade with

reference to overhead wires. We have already given particulars of the result of this deputation.

THE USE OF EARTH.

The Electric Traction Committee (consisting of Mr. Morse, Mr. Greathead, Mr. Gain, and Mr. Sellon) had been appointed to deal with the very important question of the use of the earth return by telephone and tramway companies. Major FLOOD PAGE explained that the section desired to do all they could to save litigation between the telephone and tramway companies, which might involve the cost of £100,000. An action was now pending between the National Telephone Company and the Roundhay Electric Tramway Company (Mr. Graff Baker)—and on one side it was said this suit would settle the question for ever, while on the other, that it would not settle it at all. The committee had gone a step in advance, and a meeting was to be held in a day or two, to attempt a settlement of some *modus vivendi*. The reason of the difficulty was the insistance of Government upon the insertion of protective clauses for the telephone companies in the Bills for electric railways. It was maintained, on the one side, by the electric tramway companies that they had as much right to the earth as the telephone companies, and that with a small outlay for twin wires they could obviate all disadvantages. The telephone companies, on the other hand, maintained that the present system was sufficient for their purpose and that Parliament acknowledged their rights by the insertion of protective clauses in all electric railway Bills. It had been pointed out, however, by Mr. Sellon that the Sandgate and Hythe Bill did not contain these clauses. Mr. Bennett, of the New Telephone Company, had suggested a halfway measure in the Maclure system, in which a second circuit for every two wires was used instead of entire duplication. Major Flood Page hoped that it was possible to agree upon some arrangement that both parties should have the use of earth, or in any case that something might be done to avoid litigation.

CHICAGO EXHIBITION.

The next item on the agenda, and the principal one before the meeting, was the representation of the electrical trades at the Chicago Exhibition.

Mr. W. H. PREECE, who had been invited to attend and explain the position, said the chances of a successful display by the British electrical industries at Chicago was at present very remote. On the other hand, in the industrial arts' section, the most magnificent display ever sent from this country to any exhibition was going to Chicago from over 1,500 exhibitors. The space here had to be extended, while out of 20,000 square feet given for electrical exhibitors only 5,000ft. had been taken up. Those who had sent in applications included the Epstein Company, accumulators, 220 square feet; the Electric Construction Company, 1,000ft., a large show; Parsons and Co., 220ft., three types of turbo-generators; Willans and Robinson required a large space; Ferranti and Co., alternate current motors, dynamos, and other apparatus; the General Electric Company; and the Post Office, who would send over the historical display shown at the Crystal Palace; of the rest there were only Robert Ewing, conduits; J. G. Lorrain, ventilation, Anders and Kottgen; Elmore's American and Canadian Company; London Electrometallurgical Company, silver-plating; the Phonopore Syndicate; the Collier Telephone Company; and the Homacoustic Company. He thought they would agree with him that, as the matter stood, the British electrical industry would not be adequately represented. His object in attending the meeting was to endeavour to obtain the assistance of the Section to secure some complete and typical exhibit of the methods of central station work and the lighting of private houses and buildings in England. He thought it might be possible to form a kind of syndicate amongst proposing exhibitors to fit up houses with complete suites of English furniture and electric fittings all of the best kind. He thought a number of firms might be asked to subscribe a sum, such as £250 each, to exhibit their wares. Government was prepared to give some help. Circulars had also been received from the Chicago authorities asking English contractors to tender for the lighting of certain places set aside for European exhibitors.

Mr. GARCKE said the section was greatly obliged to Mr. Preece for his explanation and suggestion. He thought a number of firms might respond, and suggested a circular should be issued. At the same time he thought a smaller guarantee than that mentioned would suffice. With the larger firms the question was more difficult, as they had difficulties in exporting their machinery, and no great hopes of extending their business in America.

Mr. BINSWANGER said that the main question should not be lost sight of—Chicago was an exhibition, not for the United States alone, but for foreign countries, and would be a great meeting place for persons from South America, Canada, and the Colonies. It was of the utmost importance to English manufacturers to have a good exhibit. Electrical engineering had passed its experimental stage, the resources are great, and the race for foreign markets will be extremely keen, and in this direction the Chicago Exhibition would have a very great importance. He mentioned that during the last three or four years his firm had established business connections in Canada, Mexico, Japan, and China, and in nearly every case his customers told him they intended to visit Chicago, and hoped to see their goods. The progress made by English men of science and the fire offices in safety, in costly engines and dynamos of immense capacity, have set the industry on a sound and independent basis as compared with that of other nations. He thought it well for every class to be represented in the electrical section, as where a customer bought dynamos he would prefer also to buy fittings, cables, and lamps.

Mr. PREECE, in answer to a question from Major Flood Page, said it was distinctly conceded that British manufacturers could mark their goods with English as well as American prices; and although there had been rumours that the McKinley party intended to refuse this right, Sir H. Trueman Wood, who had gone over with a strong ultimatum in case this were true, cabled back the first day that everything was arranged most satisfactorily.

Mr. ERSKINE suggested there need not be great expense in fitting up houses, as the furniture firms would doubtless be glad to exhibit.

The SECRETARY (Mr. Murray) said he had recently approached the wholesale furniture firms, and would do so again. If one trade commenced the others would join.

Mr. MARSHALL stated that the steam engine makers had practically resolved not to exhibit. The agricultural engineers had had a meeting, and decided unanimously that it would not be advisable to send to Chicago on account of the prohibitive duty and the large expense.

A committee, formed of Messrs. Garcke, Flood Page, and Binswanger, was appointed to draft a circular, Major FLOOD PAGE remarking that his own company were in the difficulty, as were several others, as they could not well compete with their parent companies in America. When the circular was answered they would call a further meeting, probably in October. Mr. PREECE thought they could not do better.

OVERHEAD WIRES.

Major FLOOD PAGE gave a report of the deputation, consisting of himself and Mr. Edmunds, which waited upon the Board of Trade with reference to the proposed Overhead Wires Bill. He went over the points, which were given in our report of that deputation, stating that out of 22 clauses they objected to all but five. All had been settled satisfactorily to the electrical trades, save the last and most important one—the clause by which owners of wires were compelled to give or secure permission for the officers of the local authority or the County Council at all reasonable times to inspect the wires and standards. He pointed out that this would be most restrictive to the telephone industry, as wayleaves would be simply refused under this condition. The companies should rather be required to "endeavour to obtain permission."

Mr. A. R. BENNETT expressed great gratitude on behalf of his company for the work Major Flood Page had done. The companies were now contented with the by-laws with this one exception. Wayleaves were difficult enough to obtain already; with this restriction they would become well nigh impossible to obtain.

General WEBBER thought there should be little difficulty in introducing into the wayleave agreements a

clause which would permit an official of the local authority, in the interest of public and private safety, to inspect the attachment by the officers of the company. With such a clause, worded carefully, he did not think that wayleaves would be refused. As to the wayleaves already obtained the question was much more difficult. In such cases the local authority are bound to show how the leave to inspect is to be obtained.

A resolution was carried, empowering the committee to do their best to obtain amelioration of the objectionable clause.

OTHER MATTERS.

Mr. EDMUNDS had placed on the agenda for discussion the following questions: Standardising of machinery; uniformity of prices; and foreign competition. In the enforced absence of Mr. Edmunds, it was thought these subjects were too wide to discuss at that meeting.

The section then agreed to adjourn till October, unless something of importance should arise in the meantime.

THE CRYSTAL PALACE EXHIBITION.

THE HIGH TENSION EXPERIMENTS.

BY SYDNEY F. WALKER.

In his previous article the writer omitted to mention one very great advance that has been made in the 10 years which have elapsed since the former electrical exhibition was held at the Crystal Palace.

In 1882 we were using tensions of 2,000 volts, but we were doing so in a timid sort of way, fearing that some accident or the other would happen. And accidents did happen, cutting off men in the prime of life, or occasionally allowing them to be rescued by a friendly knock-down blow from a fellow-workman. To-day we are using tensions of 10,000 volts, without accident to life so far; and tensions of 2,000 volts, whatever may be said as to the wisdom of employing them, are quite common. But, more than that, we have had Mr. Nikola Tesla showing us that very high tensions indeed may be used, provided that certain conditions accompany their use, and we have also, day by day, one of Messrs. Siemens's electricians handling tensions of 20,000 volts and 50,000 volts with the same ease and safety that we handle an ordinary 100 volt electric light service.

But, apart from the striking advance shown by these facts, the experiments themselves that are performed by Messrs. Siemens's representative afford us many very important lessons. They bring us a good deal nearer many of the puzzling phenomena that we are accustomed to associate with lightning discharges, while, on the other hand, they show us that the currents produced by means of these high voltages obey the same laws, whatever form they take, as currents produced by tensions of only 50 or 100 volts. We see, on the one hand, by the aid of these high tensions, phenomena that usually take months, or, perhaps, years, to mature, brought about in a few minutes, and, on the other hand, we see before our eyes, by the aid of currents produced by high voltages, the power that is able to perform many of the mighty feats for which lightning is noted.

Often have students of electrical phenomena, when studying the apparent freaks of lightning discharges, been puzzled, nay, baffled, by the stupendous nature of the work performed—work that is frequently out of all apparent reason, when compared to the power that is present. We hear, for instance, of a huge coping stone, forming part of the massive tower of some old church, hurled violently out of its place because the lightning discharge had a fancy to pass through to an iron rod on the other side. Or, again, for no apparent reason, beyond the existence possibly of a gas-pipe somewhere near. Sober, solid looking washstands with heavy marble tops have been known to execute something like a war dance. Whence comes this power? Some years since, the writer's observation, following on a remark of Mr. Preece's, led him to the conclusion that the secret source of the enormous energy exerted in the above phenomena was to be found in the instantaneous generation of steam from the water present within the pores of the stone, brickwork, etc., passed through by the current. It is well known that all brick and stone, even the closest, are porous, and therefore hold a certain quantity of water in suspension, that being the reason so many of the walls of our houses are damp. It is also well known that when water is converted into steam, it immediately occupies a space 1,700 times that which it occupied as water. Given, therefore, the facts that water is present in these brick or stone walls, that it is converted instantaneously into steam *in situ*, and we have expansive energy enough present to account for all that has previously so puzzled us.

But up to the time the high-tension experiments before referred to were made, the reasoning given above, though apparently sound, was necessarily based on theory to a large extent. Now, however, we have the whole phenomena produced at will before our eyes, and with a much lower voltage than we know to be present in most lightning discharges. Is it thought an extravagant idea to suppose that a spark, or a lightning flash, which is the same thing, could pass through porous, waterlogged bricks and stones? Here we have it passing through solid glass. Is it thought a stretch of imagination to conceive that steam is generated from the water held in the bricks or stones? Here we have steam formed from dropping water under our own eyes, and not only that, but, if the writer's recollection of the experiment serves him aright, actually decomposed into its constituent gases, and the inflammable one, hydrogen, set on fire.

Again, in the early days of electric lighting, such phenomena as the following were frequent, and in these days are still occasionally to be seen. An apparently non-conductive wood board, such as a wire casing, after having been in use as a protector of electric light wires for some little time, suddenly becomes a charred mass, and perhaps sets fire to neighbouring combustible material. How does this happen? A study of the principles of the science leads to the conclusion that the moisture held in the pores of the wood forms a path for a small current of electricity which silently, and usually imperceptibly, alters the nature of the wood altogether, gradually converting it into a conductor of sufficiently low resistance to allow a larger current to cross and then at some favourable point to throw a spark; the latter phenomena being followed by the charring of the wood, or its complete combustion, according to the conditions present.

But, though we can be reasonably certain of this from careful and long-continued observation of the objects, after the work is done, we cannot see it in actual progress. We hardly even suspect it, except by the indirect method of frequent insulation tests, and then not with any degree of certainty. In the experiments at the Palace, however, we see the process actually going on. We see a piece of wood placed in such a position, and of such a length that we should say it was practically an insulator for currents of ordinary lighting voltage. Yet, again, under our own eyes, and in the space of a few minutes, at the bidding of the operator, we see the wood gradually lose its normal appearance; we see it gradually change till it becomes a charred, blackened mass; we see sparks apparently darting through its mass, igniting small outlying splinters and finally we see an arc formed clear across the charred mass while the latter is evidently still conducting some portion of the current.

In the writer's opinion, this is very much what goes on in all cables which have a conductor in close proximity to the outer surface of the insulating envelope. Just as with the glass, and the stick, when exposed to the pressure of 20,000 volts, a state of severe strain is set up, which will in time break down the insulation at some favourable point, and possibly set fire to combustible material in the neighbourhood. The writer has had a case under his notice where with a pressure of only 65 volts, a spark passed between the inner copper conductor and its iron external armour, fusing some of the iron wires and setting fire to a cargo of cotton which it passed through, and which that type of cable had been specially designed to protect.

Do not these experiments also show us that breakdown tests are wrong? If a cable or other apparatus successfully withstands a breakdown test, it is supposed to be more reliable than one that has not been subjected to the same test. Yet a glance at the action of the current on the stick

or the glass will show that such a test as that, for instance, if applied for any sensible time, must seriously weaken the insulating properties of the material experimented upon. The insulation may not be broken down, because the strain is not kept up long enough, but the material is not the same as it was before the test is applied, and has not the same power to resist the passage of leakage due to even low tensions as before. A strip of rubber, if stretched only slightly, may be strained hundreds of times, and will always go back to its original form, or nearly so, but once stretched beyond a certain limit, the strip never comes back to its old form again.

In the writer's opinion, there is only one form of test that is of value for any apparatus—viz., a close imitation of the actual conditions of working, carried on for a long period of time, with possibly a slight increase in the strain applied, above the normal working conditions. This, supported by close and persistent observation of the apparatus in actual work, gives us real experience of the highest value. But the importance of such experiments as those shown by Messrs. Siemens can hardly be exaggerated as an aid to our experience. They enable us to see visibly, going on, what a careful study of principles and observation of results have taught us to imagine as going on, though hidden from our view.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

VI.

(Continued from page 302, Vol. IX.)

RESISTANCE, *continued.*

Wheatstone's Bridge (continued). The original form of Wheatstone's Bridge consists essentially of a stretched piece of uniform high resistance wire, (N)(M) Fig. 5, about one metre long, from which it derives its name, the *Metre Bridge*

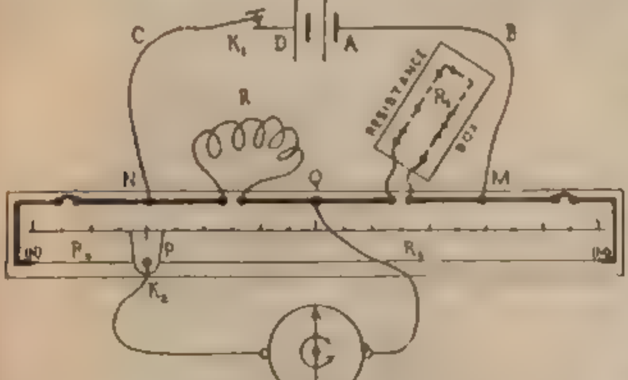

FIG. 5.—Diagram showing Single Wire Metre Bridge and Connections.

A contact maker, P, which really constitutes the key of a sensitive galvanometer, is made to slide up and down along the wire and in front of a calibrated scale, so as to vary the lengths, and correspondingly the resistances, of the portions R_2 and R_3, of the stretched wire on either side of it, the relative values of these two resistances being read off from the calibrated scale. A broad strip of copper, (N) N Q M (M), whose total electrical resistance is quite negligible, is laid along the base-board of the Bridge, and completes the apparatus. This copper strip is furnished with binding screws and removable portions as shown, to permit of the insertion of R, the coil whose resistance is to be determined, and R_1, a known variable resistance which usually takes the form of a plug Resistance Box or a calibrated Rheostat. Besides these, one or more additional known resistances are sometimes introduced into the circuit in special cases, to increase the accuracy of the readings. At the points N and M are binding screws for connecting up the battery circuit, which consists of a battery D A, of a fairly constant type such as a Daniell, and a contact-maker K_1; and at the points P and Q are screws for connecting the galvanometer circuit, which consists of a sensitive high resistance galvanometer (such as a Thomson, Deprez, or D'Arsonval reflecting instrument, some form of zero instrument, or even a telephone receiver), and the sliding contact-maker P, which fulfils the function of the galvanometer key K_2.

In this, as in all other forms of the Wheatstone's Bridge, the battery circuit and the galvanometer circuit may be interchanged, without in the slightest degree affecting the principle of the apparatus or influencing the results obtained, but the arrangement shown in Fig. 5 (in which the sliding contact-maker P forms the galvanometer key and not the battery key) will be found the more convenient of the two for ordinary measurements.

FIG. 6. Single-Wire Metre Bridge.

Fig. 5 shows diagrammatically the *Single-Wire Metre Bridge* in its simplest form, with all its connections made in readiness for measuring a resistance, and the commercial form of the instrument as sold and used is illustrated in Fig. 6.* A more elaborate form of the instrument, known as the *Five Wire Metre Bridge*, in which the single wire (N)(M), is replaced by a long wire stretched five times from side to side, and which is therefore capable of much more accurate work than the single-wire instrument, is illustrated in Fig. 7*; and other forms have been constructed with a considerably greater number of wires than this.

In Figs. 5 and 6 it will be seen that besides the two removable pieces for the insertion of R and R_1, there are two other places, one between M and (M), and the other between N and (N), where the circuit may also be interrupted and additional resistances inserted. When these additional resistances are used, they have to be added to the resistances of the adjacent portions of the stretched wire, in determining the value of an unknown resistance. In this case, therefore, it is necessary to know the actual resistance of the stretched wire in order to arrive at the value of the ratio $\frac{R_3}{R_2}$. It is often desirable to make measurements with these auxiliary resistances thrown in, so as to obtain the value of the resistance R to a greater degree of accuracy. This method of measuring resistances is illustrated in Example 2.

The total resistance of the wire in a Single Wire Metre Bridge is usually about five or six Ohms, although in special cases it may be increased to many Ohms, or reduced to the fractional part of an Ohm. The wire is usually made of German silver, platinoid, phosphor bronze, or silicon bronze for fairly high resistances, and of silver or copper for very low resistances.

FIG. 7.—Five Wire Metre Bridge.

As ordinary commercial wire is found to vary somewhat in its electrical resistance throughout its length, instead of dividing off the scale into exactly equal divisions from end to end, it is advisable to calibrate the stretched wire between its two ends, marking off the scale in such a way that the scale divisions portion off the stretched wire into small parts of equal resistance. The principle on which this is done is somewhat analogous to the method of cali-

* Figs. 6 and 7 are examples of Single Wire and Five Wire Metre Bridges, as made by Messrs. Nalder Bros., London.

brating a thermometer tube in order to compensate for slight variations in the bore of the tube.

Example 1. In Fig. 5, suppose that the apparatus has been fitted up as shown, for measuring the resistance R of a coil of wire; and that the plugs removed from the resistance box, are respectively 40, 20, 10, 4, 3, and 1, so that R_1 is equal to 78 ohms. Then if the galvanometer spot indicates no deflection when the sliding contact maker is just in the position shown, the value of R, the resistance which is being measured, will be found as follows:

$$R = R_1 \times \frac{R_2}{R_3},$$
$$= 78 \times \frac{20}{80},$$
$$= 19{\cdot}5 \text{ Ohms.}$$

The total resistance of the coil is therefore equal to 19·5 Ohms.

Example 2. As in the previous example, let the bridge be connected up as shown in Fig. 5, with the addition that the removable piece between N and N_1 is taken out and a coil whose resistance is 60 Ohms is inserted in the gap, and that a coil of 30 Ohms resistance is inserted in a similar manner between M and M_1, the total resistance of the stretched wire having been found to be exactly 8 Ohms. Then when the plugs 100, 40, 30, 3, and 1 have been removed from the resistance box, and the sliding contact maker P has been brought to the position shown, if the galvanometer shows no deflection, the resistance of R will be found as follows:

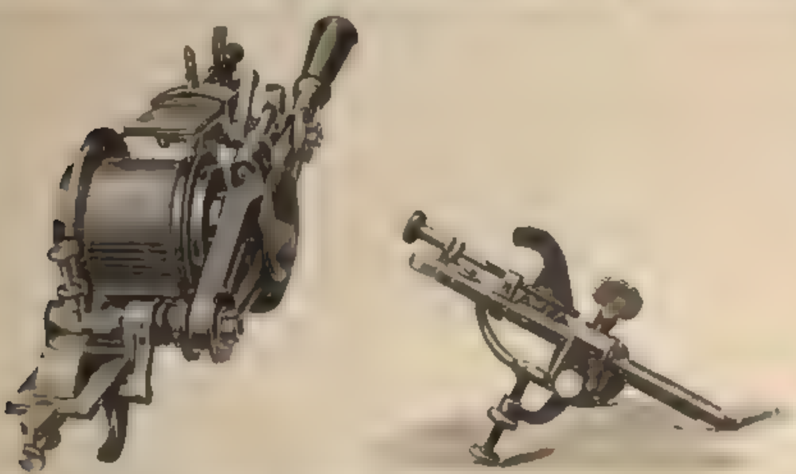
$$R_1 = 100 + 40 + 30 + 3 + 1 = 174 \text{ Ohms.}$$
$$R_2 = 30 + 8 \times 0{\cdot}6 = 34{\cdot}8 \text{ ,,}$$
$$R_3 = 60 + 6 \times 0{\cdot}2 = 61{\cdot}2 \text{ ,,}$$
$$R = R_1 \times \frac{R_3}{R_2},$$
$$= 174 \times \frac{61{\cdot}2}{34{\cdot}8},$$
$$= 306 \text{ Ohms.}$$

The total resistance of the coil is therefore equal to 306 Ohms.

(To be continued.)

TRADE NOTES AND NOVELTIES.

The Newton Electrical Company, of Taunton, have some very convenient pieces of apparatus for installation work well worth the attention of electrical engineers. One of these is their patent adjustable brushholder, which we illustrate herewith.



Newton Adjustable Brushholder.

A difficulty with brushes is that they require shifting when the dynamo is running, and with the usual type of brushholder this is sometimes a difficult or ticklish operation. With the Newton brushholder the copper gauze is carried in a holder sliding in a slot, with a screw attachment. To alter the lead of the brushes, or allow for wear, all that is necessary to do is to turn the milled head, which is easily reached, quite away from the brush itself. The brush can be altered to any position of least sparking with the utmost ease. The holder has also a cam arrangement for raising or lowering the brushes to the commutator with a single simple motion of a catch handle. The whole brushholder is ingenious and effective.

The other piece of apparatus shown is an automatic cut-out for charging accumulators. The principle is the combination of two hollow magnetic shells whose polarity is changeable by alternation of the current. When the dynamo is started and the E.M.F. rises sufficiently the lower magnet is excited, and the attraction causes a slight movement and the contact seen to one side throws the cells into circuit. This also puts the main circuit through the upper magnet, making it of opposite polarity to the lower magnet, giving, therefore, strong attraction as long as the main current is going into the cells. When the E.M.F. of the cells rises sufficiently, or when the E.M.F. of the dynamo falls, the current in the main circuit reverses, coming out of the cells, and the polarity of the upper magnet is immediately changed, repelling the lower magnet, and thus breaking the circuit. Their charging cut-out is very sensitive, and acts very satisfactorily. The sensitiveness is adjustable by a thumb set screw.

Newton Automatic Charging Cut-out.

BLACKPOOL.

The following is the report of the Committee on Electric Lighting:

In pursuance of the resolution passed by the Electric Lighting Committee on the 20th November, 1891, and confirmed by the Council on the 1st December, 1891, the following members of your sub-committee — viz., Mr. Councillor Pearson (chairman), Mr. Alderman Cardwell, and Messrs. Councillors Sergenson and Smith — beg to report as follows:

Accompanied by the borough surveyor, they visited Bradford, Huddersfield, London, Chelmsford, Fareham, Eastbourne, Brighton, Deptford, and districts near London, with the object of inspecting the various systems of electric lighting, and obtaining the fullest authentic information as to the commercial success or otherwise which has attended the application of electricity for lighting and general industrial purposes at these places.

The above-mentioned members of the sub-committee, together with the Mayor and Mr. Councillor Nickson, visited Huddersfield on the 16th December and Bradford on the 17th December, 1891. They were informed that the Corporation of Huddersfield had entered into a contract with the Brush Electric Lighting Company to instal the borough with both public and private lighting, the principle to be adopted being the high-tension alternating current system. The Corporation had not appointed an electrical engineer, but the subject was under consideration, and the Corporation are now applying for powers to borrow £50,000.

At Bradford your sub-committee found that a most extensive and complete installation of incandescent lighting had been inaugurated on September 20, 1889, on the principle known as the low-tension continuous-current system. The installation has been designed for the Corporation, and superintended during erection by their electrical engineer, Mr. James N. Shoolbred, of Westminster, and the whole of the electric plant, including dynamos, cables, electric instruments, and appliances of all kinds for the regulation of the current have been constructed and laid by Messrs. Siemens Bros. and Co., of London, all the streets being opened and made good by the Corporation. The average distance from the station to the area of supply is about 1,000 yards, and the largest cable used has a sectional area of 0·8 of a square inch of copper. The storage room contains 65 accumulators by Crompton and Co. These accumulators keep up the supply from 10.30 p.m., when the engines are shut down until about 11 a.m., when smaller engines are started. The number of customers supplied is about 150, requiring some 16,000 lamps each of 8 c.p., the demand being confined almost entirely to large warehouses, clubs, offices, hotels, and shops. The engineer to the Corporation, as well as the customers, admit that the cost is twice double that of gas, yet the latter are content to continue the use of electricity for lighting purposes, recognising fully its decided advantages over gas. The price charged is 6d. per Board of Trade unit; the capital invested is about £35,000, and the annual revenue about £4,000; the sinking fund being calculated as for a repayment in 30 years. The price of gas charged in Bradford is 2s. 3d. per 1,000ft., the Corporation being owners of the gas works as in Blackpool. Your sub-committee were received with the greatest courtesy by the Mayor, the town clerk, etc., and Mr. W[illegible], assistant electrical engineer to Mr. Shoolbred, manifested every disposition (in acting as conductor over the central lighting station) to put them in possession of the fullest and most reliable information with regard to their installation.

the side streets by 222 incandescent lamps, of 32 c.p. The current is carried by means of overhead cables, and the high tension alternating current system is employed.

The whole of the plant has been laid down and the complete installation carried out by Messrs. Crompton and Co., to whom the Town Council, who have abandoned gas altogether, pay £22 10s. for each arc lamp, and £2 6s. 10d. for each incandescent lamp per year, the lights to burn from sunset to sunrise all the year round. Messrs. Crompton's electricity works at Chelmsford were inspected, and through the courtesy of Mr. Albright some exceedingly interesting exhibitions of the manufacture of dynamos, arc lamps, and other electrical appliances were witnessed. Messrs. Crompton were also invited to interview the full committee at Blackpool, and to specify and tender for the installation of the borough. Several interviews have been held, and a specification and tender have been received from them.

Your sub-committee having thoroughly examined the Thomson-Houston system (especially as regards street lighting), and witnessed the same subjected to the severest tests, then resolved to inspect for the purpose of comparison the central stations, plant, and system of working (both arc and incandescent lighting) of the Brush Electrical Engineering Company. They therefore placed themselves under the conduct of Mr. Sellon and Mr. Raworth, the engineers and joint managers of the Brush Company, and proceeded to inspect their central station at Meredith Wharf, Bankside, Lambeth. At this large station all the current necessary to instal the western half of the City of London, as per this company's very large contracts with the Commissioners of Sewers, for both arc and incandescent lighting is generated. The high tension alternating current system is employed for the incandescent lighting, and the low tension continuous current by separate dynamos for the arc lighting, and with the exception of the boilers, which are Babcock Wilcox, all the machinery, including engines, dynamos, exciters, etc., are manufactured by the Brush Company, and are their own patents. Queen Victoria-street, which is lighted from this station by 26 arc lamps, each of about 2,000 c.p., placed 45 yards apart, diagonally, is one of the best lighted thoroughfares in the country, and affords an excellent example to compare with King William-street, which is illuminated by Thomson-Houston lamps of similar power. The lighting of these Brush Company's lamps costs £26 per annum each, and the lamps are lighted from dusk to dawn. The Brush Company's electrical works at Lambeth were also visited, and an inspection was made of their special exhibits of the latest types of electrical appliances and machinery at the Crystal Palace, where Mr. Garcke, the managing director for the Brush Company, courteously received your sub-committee, and, together with Mr. Sellon and Mr. Raworth, gave them every information regarding the object of their visit. The experience of this company is that the average cost to "wire" a house or shop is about 20s. to 25s., and they charge for the supply of current to consumers in London 7½d. per Board of Trade unit. The Brush Electrical Company were also invited to interview the full committee at Blackpool, and to specify and tender for the installation of the borough. Several interviews have been held, and a complete specification and tender have been received from this well-known manufacturing company.

The Chelsea Electricity Supply Company's system is a combination of moderately high pressure direct current, using accumulators and direct current transformers for low pressure discharge. Their central station at Draycott-place, Chelsea, was found to contain a vast number of accumulators, and a continuous current transformer, so that lamps in the neighbourhood could be lighted either from the dynamos direct, or from both, simultaneously. The mode of distribution employed is, that currents of moderately high pressure (from 500 to 1,500 volts) are distributed by a charging main to sub-stations at convenient distances throughout the district. Storage batteries are placed in these sub-stations, which, after being charged from the high pressure mains, are then switched on to the low pressure lamp service. There are 1,250 houses and shops in the company's district of Chelsea, and out of this number the company have on their books about 300 consumers, taking current for the supply of about 22,000 8 c.p. lamps, or its equivalent. They have rarely more than 10,000 lamps in use at any time. Willans and Robinson engines, Babcock Wilcox boilers, Elwell Parker's dynamos, and continuous current transformers, and the Aron meters for measuring, are in use at this station.

Another district visited which is successfully installed by this combination of high and low pressure and storage batteries, is the Sydenham and Crystal Palace District Company's area, and their system and financial prospects were fully enquired into, with the assistance of their manager, Mr. Geo. Offor. By adopting high-pressure mains this company is now enabled to supply about 500 h.p. of electrical energy, and to transmit the same to the Crystal Palace for the purposes of the Electrical Exhibition. The price charged to consumers by this company is 8d. per Board of Trade unit, this price being equal to about ¼d. per 8 c.p. lamp per hour. The same types of machinery are used as at Chelsea—Babcock Wilcox boilers, Willans and Robinson engines, Elwell Parker dynamos, and King's patent continuous current transformers.

The Westminster Electric Supply Corporation's central station at Millbank-street was visited by your sub-committee, accompanied by Mr. Sharpe and Mr. Kent, electrical engineers of Westminster, who introduced the deputation to Prof. Kennedy, the consulting engineer to this electric company. This central station was found to be so well arranged that, in the committee's judgment, none of the stations which had been inspected excelled, and very few equalled, it in general appearance and the symmetrical arrangement of all the machinery. The method of working is a direct current storage one, and the mains are laid on the three-wire system. The total number of lights connected to the mains of the Westminster Company is about 70,000 8 c.p., and of these about 25,000 are run at full load. The company have three central stations—one at Eccleston-place, Belgravia; one at Davies-street, Mayfair; and the one at Millbank-street; and by an arrangement which has been made for supplying all the lights off a main ring, to which all the stations are connected, the current is supplied from all these three stations. In the Millbank-street station there are five boilers by Babcock Wilcox, eight engines by Willans and Robinson, five dynamo machines, two by Mather and Platt, and three by Goolden and Co., and complete condensing apparatus was put down, and was in daily use. Two switchboards are fixed, one at either end of the room, the larger one being for the general supply system, and the smaller one for the Houses of Parliament. The latter is quite distinct from the other circuit, no other lights being controlled by it than those installed in the Houses of Parliament. The switchboards are both by Messrs. Crompton and Co., Limited. The accumulators employed are the Crompton-Howell, the present plant consisting of three sets or batteries, each set having 54 33-plate cells. The meters used are the Aron instruments of the improved type; Messrs. Sharpe and Kent were the contractors for the installation of this station and plant.

Another important installation which your sub-committee visited was at Brighton. This is also worked on the low pressure continuous current system, and is owned by the Corporation of Brighton. The deputation received all courtesy and information respecting the central station, and the supply of the current, etc., from the Mayor, who was accompanied by Mr. Talbot, the deputy town clerk, Mr. Wright, the resident electrical engineer, Mr. Nebel, the superintendent of works, and several members of the Council. The Corporation have already expended £43,000 on the installation, and they are now seeking powers to extend their area of supply, which will necessitate a further considerable outlay for extra plant for sub-stations, etc. The present station will supply 10,000 lamps of 8 c.p. for incandescent lighting, no arc lighting being attempted by the Corporation for street lighting. Their borrowing powers extend for a period of 30 years, and they are now applying for a supplementary loan to extend over the same period. They are supplying about 4,000 lamps with current, and their charge is 7d. per Board of Trade unit, the number of lamps lighted at any one time being 2,000, and their largest customer is the Alhambra, which is installed with over 300 lamps. This is considered to be very good business for the short time in which they have been running (about four months only), and, of course, no profit or loss can as yet be estimated, though the mayor expressed his opinion that loss must arise on the present output, but that if the maximum current be supplied a profit may be made, as the only increased outlay will be in the direction of wages and coal. The Brighton Lighting Committee consider their low pressure continuous current and storage battery system the best for compact districts with plenty of consumers. The Council recommend strongly the keeping of the electric lighting order in the hands of the Corporation, and have great faith in the future development of the electric light. Your sub-committee learned here, as in Bradford, that, lamp for lamp, the electric light costs the consumers about double the price of gas, but the consumers' expectations were more than realised by the improved condition of health and cleanliness, smaller fire risks, clearer atmosphere, a better light, and the absence of destructive effect as the result of the electric lighting ... gas. Your sub-committee were informed that consumers were all satisfied and their number was rapidly increasing. About 20 miles of cable have been laid in small subways under the footpaths, and the compulsory area in question is about a square mile. The plant consists of three Lancashire boilers ... acting as a stand-by, with space for three additional boilers; three compound direct coupled engines, by Willans and Robinson, each developing 98 i.h.p. at 450 revolutions. The dynamos, electrical apparatus, etc., are all by Siemens Bros., and Goolden and Co. Several descriptions of meters are in use, ranging from [illegible] to 100 lights, the Aron (prime cost £5) being hired out at [illegible] a year, the Corporation keeping all meters in repair. The working hours at the station are from 2 p.m. to 10 p.m., when steam is shut off, the batteries supplying current for the remaining 16 hours. The price of coal at Brighton is 22s. per ton and the charge for gas is 2s. 9d. per 1,000 cubic feet. Brighton is also possessed of another system of distribution, which is competing keenly with that of the Corporation for the lighting business of the borough. This installation belongs to the Brighton and Hove Electric Light Company, and is worked on the high pressure alternating current system, and without the aid of storage batteries. Messrs. Hammond and Co. were the engineers and contractors for this company, and Messrs. Hammond's London manager, Mr. Goodle, and Mr. Hodgson, the manager for the Brighton and Hove Company, conducted your deputation over the central station and plant, and supplied the following information to them. The capital of the company is only £17,500, and they can, with their plant, serve the whole of the area of Brighton, including the area served by the Corporation, their wires being laid now at a distance of over [illegible] miles from the station. At the time of your sub-committee's visit 10,000 8 c.p. lamps were running, this number showing an increase over the year 1890 of 3,319 lamps. The cost of the mains for the Corporation supply was over £18,000, whereas the company's mains only appear in their books at £5,000. This item of mains is one of the principal differences in cost between the high and low tension systems. The company further claim that by the use of the high pressure system the excessive waste connected with the use of accumulators is avoided, as well as the heavy cost in mains. The company charge 7d. per Board of Trade unit in the area within which they compete with the Corporation, and 8d. outside. The total length of mains laid is about 12 miles, covering nearly

the whole of Brighton and Hove. Mr. Hammond is the chairman of the company, and they have paid 5 per cent. dividend on their capital for several years.

Eastbourne: Messrs. Hammond and Co. were also the electrical engineers and contractors for the Eastbourne Electric Light Company, which is stated to have been the first company in England to supply electrical energy for both public and private lighting from a central station. The capital of the company is £28,000, and they pay 6 per cent. for their debenture capital. The system used is the high-pressure alternating current of 1,800 volts at the central station, which is transformed by means of Lowrie Hall converters down to about 100 volts before entering the consumer's premises. This company supply the Corporation of Eastbourne with the arc lighting for the Promenade. A special engine drives a Brush dynamo for this lighting alone, starting an hour before sunset and closing at 11.30 p.m. This public lighting of the Promenade consists of 16 Brush arc lamps of about 2,000 c.p. each, and each lamp costs the Corporation 3½d. per hour, or a total for the whole of the lamps of £480 per year. The station is supplying about 4,000 incandescent lamps of 16 c.p. out of a total capacity of 6,000, and the charge to consumers is 10d. per Board of Trade unit. Coal costs about 26s. per ton. The plant consists of Fowler's tubular boilers, Fowler's 150-h.p. compound engines, driving Elwell-Parker dynamos by belting. Westinghouse meters are used, and are hired out to customers at 5s. per quarter.

West Brompton: This is another central station and installation for which Messrs. Hammond and Co. were the electrical engineers and contractors. The capital of the West Brompton House-to-House Electric Company is £70,000, and the company was formed in 1879. Of all the stations visited by your sub committee, this was the best example for working the high tension alternating-current system by means of converters which came under their notice. Mr. Gay, the engineer and manager, with Mr C. P. Goode, the manager for Messrs. Hammond and Co., conducted the deputation over the station, and courteously and lucidly explained the system under which they were working, and supplied the fullest information as to cost of working and the power of the plant, etc. There are about 22 miles of mains laid in cast-iron pipes of 6in. diameter for the largest size. Four Babcock Wilcox boilers, working up to 120lb. pressure; four Fowler compound engines (non-condensing), one of which, of a small size, works after 12 p.m. The dynamos were of the Lowrie-Hall type, being manufactured by Messrs. Elwell and Parker, and were driven by ropes from grooved flywheels of engines. At present there are about 26,000 lamps installed, the greatest number lighted at one time being about 10,000. The station is so designed that it can be extended at any time to hold 12 engines and dynamos capable of supplying 40,000 lamps. Westinghouse meters are used, and are hired out to consumers at 5s. per quarter, and the charge made for current is at the rate of 8d. per Board of Trade unit. The engineers laid great stress upon the advantages to be gained by adopting the high tension system for a place like Blackpool, and strongly emphasised the fact that all danger is removed by this system by the employment of converters which deliver the current to the consumer at about 100 volts only. The smooth, almost noiseless working of this station; the admirable and convenient arrangement of all apparatus and machinery; the apparently highly successful system of generating and supplying electric light and power by means of the Lowrie-Hall types of alternating-current high-pressure dynamos, which are worked in parallel, and are not affected by the extinction or relighting of large numbers of lamps; the absence of all complicated machinery or instruments, together with the well-considered and exceedingly simple arrangements of the switch and testing rooms, and the satisfactory supply and steadiness of lights to consumers, powerfully and favourably impressed your sub-committee as being in every respect not only a model station but one displaying in the clearest and simplest form a system calculated to meet in an eminent degree the peculiar requirements of both public and private lighting, as well as the supply of electric motive power, for Blackpool. Messrs. Hammond and Co., engineers to the House-to House Electric Supply Company, of London, Leeds, Dublin, Coatbridge, Burton, The Scotch, etc., were invited by your sub-committee to visit Blackpool, and to specify and tender for their system of installation for the borough. Accordingly several interviews have been held by the full committee with this company, at which there have been present Mr. Robert Hammond (the well-known electrician) the principal of the company, Mr. Goode, the manager, and Mr. Hall, the chief electrical engineer, etc., and a detailed specification of their Lowrie-Hall system, together with a tender for the complete installation of the borough, have been furnished to the committee.

The sub-committee with the knowledge gained by the enquiries before named, and having had the advantages of the conferences between several electrical engineers and the full committee, and also having regard to the following considerations, have now arrived at the recommendations hereinafter set forth. The considerations which the sub committee have had in mind are:

That the Corporation are themselves the undertakers for the purposes of the Blackpool Electric Lighting Order, 1890; that the borough, which is the prescribed area of supply, is sparsely occupied in some portions, whilst in other places at long distances apart there are many streets, houses, and buildings likely to be required to be lighted by electricity; that an installation in any particular part of the borough may soon have to be extended so as to embrace a wider district of actual supply; that any area of supply in Blackpool is necessarily, owing to local conditions, irregular in form and not compact, and that for the present the consumers therein must, until the supply has been in use, and the cost to such consumer experienced, be at uneven distances apart; that in the only streets wherein under the order distributing mains are to be laid within a definite time, there is an existing installation in the form of the Marine Promenade electric lighting; that any installation should be adapted for permanent and economical working; that in carrying out any scheme regard should be had to as small a burden in the way of loans and repayment as would be consistent with efficiency and provisions for future development; that the question of street lighting in the business parts of the town must be taken into account; that apprehensions of danger from adoption of a high-pressure system must be borne in mind, and such apprehensions shown to be groundless; that it may now be assumed that the adoption of electricity as a means of public and private lighting has passed its initial or experimental stage; and that on grounds of utility, health, and attraction, the Council may now safely be recommended to undertake a supply of electric energy for such lighting in Blackpool.

The sub-committee therefore respectfully submit the following recommendations and opinions for approval and adoption:

1. That the Corporation should not transfer their powers and works under the order to any company or person, but keep the same in their own hands and control, and should employ electrical contractors to execute for the Corporation any necessary works.

2. That the best system to meet the scattered and uneven collections of probable consumers, and bearing in mind the long distances many of them will be apart, will be the high-tension alternating-current transformer system. This system, in the sub-committee's opinion, is best calculated to meet the growing requirements of such a town as Blackpool, and of further reasonable extensions without much additional expense at the central generating station, and without the necessity of providing any substations, and would also be best suitable for districts which are not compact in themselves, or where the separate consumers therein may be wide apart.

3. That the central generating station might advantageously be erected on land belonging to the Corporation at the central storeyard.

4. That the high tension alternating current system can more successfully deal with the Promenade and public street lighting than the low-tension continuous-current system, and the sub-committee consequently recommend the discontinuance of the present low-tension system of electric lighting on the Promenade and piers.

5. That for the Promenade and piers the sub-committee recommend a greater number of arc lamps than the number now in use, and that each lamp be of 2,000 c.p. instead of the present 6,000-c.p. lamps, and that same be placed at less distances apart, and on shorter and ornamental poles not exceeding 25ft. in height, in lieu of the existing 60ft. poles, as being calculated to give far more efficient illumination, and a much more even distribution of light, and at a considerably reduced cost; thus adding an additional artistic and attractive feature to the Marine Promenade. The sub-committee further suggest the same power and height of lamp for street electric lighting in those parts of the borough which the Council may determine to have lighted by electricity.

6. That the capital expenditure required for the system which the sub-committee suggest is estimated to be very much less than for the capital expenditure of any other known system. Moreover, the sub-committee believe its working would be more economical, more efficient, and better adapted for future development than the other systems.

7. That the high-tension system does not present dangerous features, because by the use of transformers the high-pressure electric current is converted into a low-pressure and harmless current before entering the premises of one or more consumers.

In conclusion, and feeling that the Council and the public, upon whom the support of any new system of lighting must depend, will expect an expression of opinion as regards the probable capital cost, and the expense to the consumer himself, the sub-committee report that they believe a capital outlay of about £26,000 would satisfactorily meet the present requirements of those parts of the borough where electricity may be demanded, either for lighting purposes or motive power, and that electric energy by the system recommended by the sub-committee can, after making provision for sinking fund and interest, be supplied to consumers at a charge not greater than 6d. per Board of Trade unit, possibly at 5d., and that if there be a fair increase in the consumption the charge may even be less than 5d. A charge of 6d. per Board of Trade unit would be equivalent to a charge of about 4s. per 1,000 cubic feet of gas of 18 standard candle-power.

Before advising the final acceptance of the particular tender recommended by the sub-committee, it is desired that the Council should first approve of the system suggested, and that in place of obtaining a report from a consulting electrical engineer as already authorised by the Council, the Electric Lighting Committee should be empowered to appoint a resident electrical engineer to advise on the specification and tender recommended by the sub-committee, and that such resident electrical engineer should have charge of the works during construction and of their subsequent maintenance.

The sub-committee venture to express the hope that their long and arduous enquiries and labours will be satisfactory to the Council and lead to the further development of the attractions and prosperity of the borough, both as a growing health and pleasure resort, and also as a residential town, by a more general adoption of electricity as a healthy and non-injurious illuminant.—On behalf of the sub-committee, JAS. PEARSON, Chairman.

29th June, 1892.

At the Council meeting last week the following report of the Electric Lighting Committee was adopted, the only question dis-

caused being the amount of the salary of the resident electrical engineer.

"Resolved that subject to revision of the specification by the Corporation's resident electrical engineer to be appointed as recommended by the sub-committee, the tender No. 2, now before this meeting, for carrying out the works advised by the sub-committee be recommended to the Council for ultimate acceptance. That the town clerk be instructed to apply to the Board of Trade for the Board's approval of the high-tension alternating current system for the supply of electrical energy by the Corporation within the borough, under the Blackpool Electric Lighting Order, 1890, and that all necessary plans and particulars be furnished to the Board. That a resident electrical engineer be appointed as recommended by the sub-committee, and that the approval of the Council be an authority to this committee to appoint such an engineer, at a salary to be fixed by the committee. That the Finance Committee be desired to direct an application to the Local Government Board, under the Electric Lighting Acts, and the Public Health Act, 1875, for the sanction of the Board to the borrowing by the Corporation, as the urban sanitary authority for the borough, of the sum of £26,000, repayable in 30 years, for the purposes of the Blackpool Electric Lighting Order 1890, on security of the District Fund and General District Rate, and any property of the Local Authority."

LEGAL INTELLIGENCE.

JOEL v. BARNET LOCAL BOARD.

The following is the text of the award, the general purport of which we have previously given.

"To all to whom these presents shall come. We, John C. Fell, of 1, Queen Victoria-street, in the City of London, civil engineer and patent agent, and John Slater, of 46, Berners-street, in the county of London, architect, send greeting. Whereas, by a memorandum of agreement, made the 6th day of July, 1888, between Henry Francis Joel, of 31, Wilson-street, Finsbury, in the county of Middlesex, electrical engineer, of the one part, and the Barnet Local Board of the other part, it was agreed that the said Henry Francis Joel should carry out a system of electric lighting within the district of the said Barnet Local Board upon certain terms therein mentioned, and it was among other things provided therein that if any dispute should arise under the said agreement the same should be referred to the arbitration of two arbitrators and an umpire in the usual way, and that the said agreement might be made a rule of court at the instance of either party. And whereas divers disputes arose under the said agreement, and in pursuance of the aforesaid provision on that behalf the said Henry Francis Joel thereupon (with the concurrence of the Barnet and District Electric Supply Company, and Thomas William Potter, who had become, or claimed to have become interested with the said Henry Francis Joel under the said agreement), did, by writing under his hand upon the 26th day of March, 1891, appoint me, the said John C. Fell, as his arbitrator to settle and determine the said disputes, and the said Barnet Local Board did, by writing under their seal on the 8th day of April, 1891, appoint me, the said John Slater, as their arbitrator, to settle and determine the said disputes. And whereas we, the said John C. Fell and John Slater, before we entered upon the matters so referred to us did on the 21st day of July, 1891, by writing under our hand, duly nominate and appoint Lumley Smith, Esq., one of H.M. counsel, to be the umpire in the matter of the arbitration, and the said umpire, with the consent of ourselves and the other said parties, and at the request of the said parties, was present when we heard the said parties and their witnesses during the said reference. And whereas for the purposes of the said arbitration and our determination therein, the said Henry Francis Joel delivered to us and to the said Barnet Local Board particulars in writing of divers breaches of the said agreement which he alleged to have been committed by the said Barnet Local Board, and the said Barnet Local Board also delivered to us and to the said Henry Francis Joel particulars in writing of divers breaches of the said agreement which the said Barnet Local Board by way of defence and consideration, alleged to have been committed by the said Henry Francis Joel, and such particulars so delivered by the said parties respectively as aforesaid were adopted by the said parties as defining the matters in respect of which our determination was desired. And whereas the said parties to the said reference at the hearing thereof concurred and agreed that it should not be necessary for us, the said arbitrators, by our award to settle or determine all or any of the other disputes or alleged breaches separately or specifically, but that we might give our award generally for the one party or the other upon the whole of the said matters of dispute and alleged breaches taken together. And, whereas, on the 23rd day of May, 1892, by a judge's order of the Queen's Bench Division of the High Court of Justice, the time for us, the said arbitrators, to make our award was enlarged until the 15th day of July, 1892. Now we, the said arbitrators, having taken upon ourselves the burthen of the said reference, and having heard the said parties and their witnesses, do hereby make and publish our award in writing of and concerning the matters above referred to us in manner following, that is to say, we award and determine that the said Henry Francis Joel is entitled to recover from the said Barnet Local Board the sum of £500, which sum we award and direct that the said Barnet Local Board do pay to the said Henry Francis Joel. And we further award and direct that the said Barnet Local Board do pay to the said Henry Francis Joel his cost of the reference and also pay the costs of the award, and that the said Barnet Local Board do bear their own costs of the same. In witness whereof we have hereunto set our hands this 29th day of June, 1892. (Signed) JOHN C. FELL, JOHN SLATER."

COMPANIES' MEETINGS.

LIVERPOOL OVERHEAD RAILWAY.

A special general meeting of the shareholders of the Liverpool Overhead Railway Company was held on Tuesday, Sir W. B. Forwood presiding.

The meeting was called to rescind a resolution passed on February 9 last, and to pass another one increasing the amount it was proposed to raise for carrying on the work of constructing the railway. **Mr Allsopp**, the solicitor to the Company, in explaining the clause of the Act of Parliament under which shareholders met, said by the original Act incorporating the Company, passed in 1888, the capital of the Company was fixed at £450,000, and its borrowing powers at £150,000. The borrowing powers were subject to the restriction that nothing at all could be borrowed until half of the capital had been issued, and then only £75,000, and after that nothing more until the whole of the capital had been issued. By the Act of Parliament passed during the present year the borrowing power was varied, and it was provided that as regarded £375,000 of the capital one third should be borrowable—namely, £125,000—if the shareholders sanctioned it.

The **Chairman** said originally it was expected the railway would cost £450,000, which was made up of £375,000 share capital and £75,000 of bonds. Originally it was intended that the railway should be worked by steam locomotive power, but it had since been determined, and he thought very wisely determined, by the Directors, and sanctioned by the shareholders, that they should adopt electricity in place of steam. The result was that instead of paying £37,000, which was the estimated cost of their steam plant, they would have to pay about £67,000, the estimated cost of the electrical plant—an increase of £30,000. From the investigations they had made, they believed that the increase was fully justified, as they were likely to save nearly 20 per cent. per annum by working their railway by electricity instead of steam. An item growing out of the adoption of electricity was the question of electrical automatic signalling, which would cost £11,000, as compared with £3,000 required for the ordinary hand signalling. Although the first cost was greatly enhanced, the cost of working the signals would be very considerably decreased. They would be worked automatically, and the saving in manual labour would be very large indeed. It would perhaps interest the shareholders to know that although the progress with the railway had been much slower than they anticipated—they had encountered as every new undertaking encountered very many unforeseen difficulties—they were now approaching the completion of the work, and they thought they could see their way clear to having the railway in active operation in October next. They had only 48 spans of the main structure to place in position, and the electric station at the Wellington Dock was almost completed. He moved that the resolution passed at the general meeting of the shareholders, held on the 9th February, 1892, authorising the Company to raise the sum of £75,000 by the creation and issue of debenture stock for that amount be rescinded.

Mr. Richard Hobson seconded the resolution, which was carried.

The **Chairman** then moved that the Liverpool Overhead Railway Company, in exercise of the power conferred by the Liverpool Overhead Railway Act, 1892, be authorised to raise the sum of £125,000 by the creation and issue of debentures for that amount, and that accordingly the Directors be authorised to issue such debentures, at such rate of interest, in such amounts and manner, at such times, and on such terms, as they might think fit.

Mr Hobson seconded, and the resolution was also carried, and the proceedings terminated.

COMPANIES' REPORTS.

ELECTRICAL POWER STORAGE COMPANY, LIMITED.

Directors: John Irving Courtenay, Esq. (chairman and managing director); Sir Daniel Cooper, Bart., G.C.M.G.; James Balfour, Esq.; Frederick Green, Esq.; James Pender, Esq. Manager: Frank King, M.I.E.E. Secretary: J. W. Barnard.

Report of the Directors, to be presented to the shareholders at the third ordinary general meeting, to be held on Wednesday, 20th July, 1892, at the offices of the Company, 4, Great Winchester-street, E.C., at 12.30 p.m.

The Directors have much pleasure in presenting to the shareholders the report and accounts up to 31st May, 1892. The gross profit and other sums receivable amount to £37,045. 12s. 2d. The Directors have made provision for maintenance of buildings, plant and tools, and depreciation, by writing off the sum of £1,401. 6s. 1d. The net profit, after payment of general expenses, management, etc., is £5,763. 11s. 9d., out of which the Directors propose to pay a dividend of 6 per cent. on the paid-up capital of the Company. This will absorb £5,017. 4s. 2d., and the remainder, viz., £746. 7s. 7d., the Directors propose to carry forward to next account. The Directors have during the past year completed the necessary arrangements for changing the name of the Company from the Foreign and Colonial Electrical Power Storage Company, Limited, to "Electrical Power Storage Company, Limited," thus restoring to the Company the prestige of the old E.P.S. name. During

the past 12 months the Company has acquired a lease of the storage battery manufacturing business previously carried on by the Electric Construction Corporation at Millwall and Wolverhampton, and included in this lease is the use of the plant, machinery, and, for a period of three years, of the stock existing at Millwall, where the business is now carried on. The accounts have been made up to 31st May, 1892, as at that date the lease of the manufacturing business from the Electric Construction Corporation, Limited, had been in existence 12 months. The shareholders will note with satisfaction from the profit above mentioned that the business of the Company exhibits marked vitality. The patents of the Company have been upheld abroad by legal decisions, which should have a beneficial effect upon the general business of the Company. The utility of secondary batteries for the work of central electric lighting stations, and the absolute necessity of such apparatus in private lighting installations being now generally admitted, the Directors are devoting attention to the commercial application of the secondary battery to electric traction. Very considerable success has attended the use of the Company's batteries for electric launch work. Some thousands of cells are, and have been, in use for this purpose during the past five years. Much activity exists among the various engineers, who are endeavouring to develop commercial methods of electrically propelling tramcars, omnibuses, and other vehicles, and the Company is in a position to profit by the successful result of their labours. The Directors are pleased to report that at the Crystal Palace Electrical Exhibition, 1892, the Company received the only gold medal for storage batteries. The retiring directors are Mr. Frederick Green and Mr. James Pender, who, being eligible, offer themselves for re-election. The auditors, Messrs. Broads, Paterson, and Co., also offer themselves for re-election.

BALANCE-SHEET, MAY 31, 1892.

Liabilities.	£	s.	d.	£	s.	d.

NEW COMPANIES REGISTERED.

Holloway Electricity Supply Company, Limited.—Registered by W. Sharp, 13, Walbrook, E.C., with a capital of £2,000 in £10 shares. Object: to carry on the business of an electric lighting company in all its branches. There shall not be less than three nor more than seven Directors. Qualification, £500. Remuneration to be determined by the Company in general meeting.

Lithanode and General Electric Company, Limited.—Registered by Paine, Son, and Pollock, 14, St. Helens-place, E.C., with a capital of £100,000 in £1 shares. Object: to adopt and carry into effect an agreement expressed to be made between the Mining and General Electric Lamp Company, Limited, and its liquidator of the one part and the Company of the other part; generally, to carry on business as electricians, mechanical engineers, gas engineers, lamp manufacturers, manufacturing chemists, contractors for public and private works, etc. The first subscribers are:

	Shares.
J. E. Huxtable, 14, St. Helens place, E.C.	1
C. H. B. Ince, 102, Alexandra-road, South Hampstead	1
L. Mossop, B.A., 7, Cambalt-road, Putney	1
C. R. Pearson, 2, Balfour terrace, High-road, Leytonstone......	1
J. E. Wood, 10, Placquett-road, East Dulwich	1
A. C. Crane, 3, Wood-lane, Highgate, N................	1
J. H. Gedge, 14, Abbeyville-road South, Clapham Park	1

There shall not be less than three nor more than nine Directors; the first to be appointed by the signatories to the memorandum of association. Qualification, £500. Remuneration, £100 each per annum; Chairman £50 extra. In addition to the foregoing, 10 per cent. on the net profits after payment of 15 per cent. dividend.

Railway Electric Reading Lamp Company, Limited.—Registered by Jordan and Sons, 120, Chancery-lane, W.C., with a capital of £100,000 in £5 shares. Object: To purchase from the Railway Automatic Electric Light Syndicate, Limited, certain patents for the United Kingdom for electric reading lamps, granted to D. H. Davies and J. M. Tourtel; and, with a view thereto, to adopt and carry into effect an agreement expressed to be made between the Railway Automatic Electric Light Syndicate, Limited, of the first part, J. M. Tourtel and D. H. Davies of the second part, and this Company of the third part; also to enter into an agreement with the Metropolitan District Railway Company, by which the Company will be authorised to instal and work automatic electric reading lamps in their railway carriages. The first subscribers are:

	Shares.
B. H. van Tromp, 4, Hyde Park-terrace, W.	1
E. Garcke, 1, Great Winchester-street, E.C.	1
E. Etlinger, 27, Cavendish-road West, St. John's Wood	1
W. H. Fox, 9, Austinfriars, E.C.........	1
J. C. Bull, 1, Great Winchester-street, E.C.	1
J. M. Tourtel, 558, Mansion House-chambers, E.C.	1
F. C. Cocking, 192, Friern-road, Dulwich............................	1

There shall not be less than three nor more than seven Directors. The first are E. Etlinger, J. H. Kincaid, C. E. Spagnoletti, and B. H. van Tromp. Qalification, 50 shares. Remuneration, £800 per annum and 5 per cent. of the net profits after payment of 7 per cent. dividend.

Richmond (Surrey) Electric Light and Power Company, Limited.—Registered by Lumley and Lumley, 37, Conduit-street, Bond-street, W., with a capital of £50,000 in £5 shares. Object: to carry out the terms and provisions of the Richmond (Surrey) Electric Lighting Order, 1883, in so far as the same may be carried out in accordance with the provisions of an agreement, made December 8, 1891, between the Corporation of the borough of Richmond of the one part and Latimer Clark, Muirhead, and Co., Limited, of the other part, and, with a view thereto, to carry into effect an agreement expressed to be made between L. Clark of the one part and this Company of the other part, whereby the benefit of the said contract of December 8, 1891, is to be assigned to the Company. The first subscribers are:

	Sha es.
W. E. Grigsby, 7, King's Bench-walk, Temple	1
Sir E. Hertslet, C.B., Belle Vue House, Richmond, S.W.	1
D. B. Hall, Heywood, Maidenhead, Berkshire........................	1
R. L. Kidd, Kewfoot-road, Richmond, S.W.	1
J. Soares, Richmond, S.W.	1
F. B. Alston, K.C.M.G., 69, Eccleston-square.........................	1
E. C. Curtis, 15, Cranley-place, S.W................................ ..	1

There shall not be less than three nor more than 10 Directors; the first to be elected by the signatories to the memorandum of association. Qualification, £200. Remuneration, £600 per annum, divisible.

BUSINESS NOTES.

City and South London Railway.—The receipts for the week ending July 10 were £733, against £692 for the same period of last year, or an increase of £41 The total receipts to date from January 1, 1892, show an increase of £1,334, as compared with last year.

Companies of the Month.—The following electrical companies have been registered during the past month:

Electrical Clock Company, Limited, £1 shares	£1,200
Electrical Coal-Cutting Contract Corporation, Limited, £5 and £1 shares	402,000
Electric Lamp Company, Limited, £1 shares	4,000
Holloway Electricity Supply Company, Limited, £10 shares	2,000
London Electric Manufacturing Company, Limited, £1 shares	10,000
Pacific and European Telegraph Company, Limited, £10 shares	100,000

Chili Telephone Company.—The annual general meeting of the shareholders in this Company took place on Monday at Winchester House, Old Broad-street, Colonel R. R. Jackson in the chair. The Chairman, in moving the adoption of the report, stated that the falling off in the income of the Company in the past year was

really small when it was remembered that the system was monopolised by the State, and that its use by the public was suspended for eight months. The subscribers had been reconnected with the exchanges as quickly as possible, and there was every indication that the Company would share largely in the return of the national prosperity. The motion was seconded and adopted. A resolution was afterwards passed declaring a dividend of 10s a share, free of income tax, upon the ordinary shares, to be represented by certificates exchangeable on presentation before March 31, 1893, for an equal amount of the Company's fully paid shares.

Telegraph Construction and Maintenance Company. A half yearly general meeting of this Company was held on Tuesday, at 38, Old Broad street. Sir George Elliot, who presided, stated that during the past half year they had carried out a contract with the Western and Brazilian Company by laying about 770 miles of cable along the coast of Brazil between Santos and Chuy, and had made various repairs in that company's cables on the same coast. They had laid a cable nearly 300 miles in length along the eastern coast of Sumatra for the Dutch Government through the Eastern Extension Company; they had made several repairs in the German Government cable between Emden, on the River Emms, and Valentia, in Ireland; they had likewise made repairs in the Direct United States Company's cable on the banks of Nova Scotia. Their general business had been fairly good compared with a similar period of last year. On the motion of Mr Hewat, a vote of thanks to the Chairman and Directors closed the meeting.

Silvertown Company. A half yearly general meeting of the India Rubber, Gutta Percha and Telegraph Works Company, Limited, was held on the 7th inst. at the City Terminus Hotel, Mr S. William Silver presiding. The Chairman stated that the general sales of the Company were increasing. The additional capital referred to at the last meeting was readily taken up, and the position of the Company had thus been much strengthened. They had manufactured and despatched the cable which was mentioned the last time they met; and their steamer "Silvertown" was now off the coast of Brazil engaged in laying the cables across the Atlantic to the West Coast of Africa. Their works, buildings, and machinery were in excellent order, and they were in a position to meet any demand which might be made on them. He concluded by proposing the payment of an interim dividend of 5 per cent., or 10s per share, tax free. Mr. Matthew Gray (the managing director) seconded the motion, which was unanimously carried.

Telephone Amalgamation in the West of England. A special meeting of the Western Counties and South Wales Telephone Company was held last Friday at Bristol to confirm the amalgamation of the Company with the National Telephone Company. Mr George White, on behalf of dissenting shareholders, protested against the arrangement, saying the terms were unfair. He had taken counsel's opinion, and it was very strong indeed with regard to the ability of dissentient shareholders to upset the agreement with the National Company, but if he went to the Court to upset the sale and was successful he should find himself driven back into the hands of the liquidator, who would deal with the property as he might choose. If he could upset the sale without landing the shareholders in this difficulty he would have done it at his own expense. The Chairman replied that what the Directors proposed was in the interests of the shareholders, and although the terms offered were not all they could wish, they were the best obtainable. The meeting confirmed the agreement.

Edison and Swan United Electric Light Company. The ninth annual report of this Company says that the business of the Company has resulted in a credit balance of £74,810. 16s. 7d. Of this amount £30,271 15s. 11d. has been already distributed as an interim payment on the A shares for the first six months of the year in respect to dividend and arrears. The Directors recommend a further distribution of a dividend on the A shares of the Company of 5s. 8¾d. per share on the 89,261 ordinary shares, £3 paid, of 9s. 6½d. per share on the 5,000 £5 fully paid shares allotted to the Edison Electric Light Company, Limited, and of 8s. 10¾d. per share on the 12,139 £5 fully paid shares allotted to the Swan United Electric Light Company, Limited, free of income tax, being, with the interim dividend paid on the 22nd February, 1892, 7 per cent., in respect of the year ending 30th June, 1892; 7 per cent. in payment of arrears of cumulative preferential dividend for the year ending 30th June, 1887, and of 4 per cent. in respect of the year ending 30th June, 1888; all to be distributed in accordance with the provisions of clause 87 of the articles of association, which will absorb £33,354 4s. 9d., leaving £11,184 15s. 11d., which the Directors have carried to the reserve fund, in accordance with clause 89 of the articles of association.

PROVISIONAL PATENTS, 1892.

JULY 4.

12350. **Working by electricity weaving and spinning machinery.** Frederick Francis Bennett and Henry Curwen, 8, Bank parade, Preston.

12381. **Improvements in the manufacture of plates for storage batteries or accumulators and the accessories thereto.** Edward Bradford Bright and Mark Bailey, Archway House, Esher, Surrey.

12392. **Improvements in the manufacture of wire stripe and the like by electro deposition.** Richard David Sanders, 4, South street, Finsbury, London.

12396. **Improvements in the lighting of railway trains electrically.** Illius Augustus Timmis, 2, Great George street, Westminster, London.

JULY 5.

12397. **An improved method of regulation of the potential difference of electrical conductors more particularly with regard to the variation caused by the varying current in the middle or "third" wire of a three-wire system.** Josiah Sayers, 49, Melbourne street, Derby.

12417. **Electric brazing and soldering devices.** Willis Mitchell, 30, Southampton buildings, Chancery lane, London. (Complete specification.)

12436. **Improvements in electric insulators.** Henry Harris Lake, 45, Southampton buildings, London. (Louis McCarthy, United States.) (Complete specification.)

12442. **Improvements relating to the lighting and heating of railway and other vehicles by electricity.** Leon Denso Adler, Joseph Loewenberg, Samuel Young, and Morris Moskowitz, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

JULY 6.

12468. **Improvements in electricity meters.** Joseph Edmondson and Joseph Oulton, Penny Bank Chambers, Waterhouse street, Halifax.

12474. **The safety arc lamp.** Robert Drysdale, 141, Upper Mary street, Balsall Heath, Birmingham.

12506. **A new improved telephone transmitter.** Rowland Hughes Jones, Norfolk House, Norfolk street, Strand.

12511. **Improvements in electromagnetic clutches.** Edith Willans, widow and administratrix of the late Peter William Willans, 24, Southampton-buildings, Chancery lane, London.

JULY 7.

12528. **Improvements in telephonic apparatus and switches.** George Lee Anders and Walther Kottgen, 10, Jeffrey's square, St. Mary axe, London.

JULY 8.

12618. **An improved combination wall socket and switch for electric currents.** Louis Schramm and Samuel Thomas Wyand, 9, Warwick court, Gray's inn, London.

12619. **An improved electric switch.** Louis Schramm and Samuel Thomas Wyand, 9, Warwick court, Gray's Inn, London.

JULY 9.

12655. **Improvements in conduits for electric or cable roads.** Percy Willis, Victoria chambers, Chancery lane, London. (Carence Harding Bates, William Alder Miller, and William Ragan, United States.)

SPECIFICATIONS PUBLISHED.

1891.

9915. **Electrical distribution.** Swinburne and Holt.
11886. **Electric arc lamps.** Cance and others.
12009. **Electric motors.** Maquay.
13114. **Electric furnaces.** Parker.
13387. **Dynamo electric generators.** Caxal.
13628. **Electric dynamos.** Hartnell.
13928. **Electric locomotives.** Atkinson and others.
14171. **Electric cars.** Grimston.
14850. **Incandescent electric lamps.** Cunningham.
14987. **Electrical drill.** Siemens Bros. and Co., Ltd., and others.
15240. **Dynamo electric machines.** Siemens Bros. and Co., Limited, and Hind.

1892.

3881. **Electrical accumulators.** Kahabka.
7172. **Electrical surgical instruments.** Bradley.
8463. **Electric arc lamps.** Cooper.
9136. **Electric alarms.** Thorn.
9282. **Telephonic installations.** Abel. (Societe Generale des Telephones.)
9470. **Electric pushes.** Lake. (Jones.)

the Irish capital will be again with light before the leaves fall.

Grimsby.—The question of lighting the Central Market by electricity is to be left over until the matter of lighting the Town Hall is completed, the Corporation (as will be seen in another column) not taking over this installation till it is in a perfect and finished condition.

Bray.—The work on the establishment of the Bray central station is now practically complete, but the date for formal inauguration is not yet definitely fixed. Several test runs are being made, and as soon as the necessary adjustments are made the permanent lighting will be undertaken.

Holborn.—The County of London (North) Electric Lighting Company, and the Islington and General Electric Supply Company have forwarded notices to the Holborn Board of Works intimating their intention of applying for provisional orders to supply electric light to the Holborn district.

Cornwall Exhibition.—Intending exhibitors, especially those interested in mining plant, should not forget the Royal Cornwall Exhibition to be held, on August 23rd, at Falmouth (see last volume, p. 533). Mr. R. B. Rogers, 10, Gerald-road, S.W., agent; Mr. Edward Kitto, Falmouth, secretary.

Colombo Tramways.—Messrs. Hutchinson and Co., of London, who have undertaken the construction of the Madras electric tramways, have applied for a concession for 21 years for a similar line in Colombo, Ceylon, but for an overhead conductor system, and for goods as well as passengers.

Surveyors' Institution.—It has been decided to light the Surveyors' Institution with electric light. The work is being carried out, under the superintendence of Mr. Morgan Williams, of the firm of Messrs. Morgan Williams and King, consulting engineers, by Messrs. Pyke and Harris, of Westminster.

Natural Currents.—A curious effect of the abnormal weather is reported from the Bengal-Nagpur telegraph system. It was found that the natural current of electricity prevailing was much greater than the artificial; so much so, that measuring the one numerically by 4 the other was represented by 9.

Southampton.—A Local Government enquiry has been held in respect to the application of the Council to borrow the sum of £660 for electric lighting at Otterbourne. The contract for the erection of the necessary plant for electric lighting at the new baths has had the Corporation's seal affixed.

Telephonic Communication with Paris.—On Monday, at 10 a.m., a call office was opened in connection with the London-Paris telephone at the West Strand Telegraph Office, Charing Cross. The office will be open day and night. The charge for telephonic communication with Paris is 8s. for a conversation of three minutes.

The National Telephone Company have recently appointed Mr. A. Calder, their London manager, in succession to Mr. Dane Sinclair, now engineer-in-chief. The appointment, while being a popular one, will tend to bring with it increased prosperity to the company, as Mr. Calder has been long in the service, and has had a most varied experience.

Poplar.—On the receipt of a letter from the County of London Electric Lighting Company to the Poplar District Board stating that they proposed to apply for a provisional order to supply Poplar with the electric light, it was resolved that the Works Committee should consider the desirability of the Board applying itself for a provisional order.

Camberwell.—The Board of Trade have written to the Camberwell Vestry, stating that the Islington and Camberwell Electric Lighting Company had failed to satisfy the Board that they were in a position to discharge the duties and obligations imposed upon them, and were in favour of a revocation of the order. The Vestry has agreed to this course.

Cannes.—The British Vice-Consul at Cannes says that lighting by electricity has been partially adopted by a certain number of hotels and villas, and also by some of the principal tradespeople. It is generally considered to be satisfactory, but as yet no attempt has been made at lighting the town; in fact, this cannot be done before the contract between the town and the gas company has expired.

Alternating-Current Motors.—The Bernstein Electric Company, of Boston, has introduced a neat little alternating-current motor for fans and other domestic purposes. The motor has no electrical connection between armature and field; it runs with one brush and without sparking. It is noiseless, self-oiling, and takes 65 watts on either 50 or 100-volt circuits. The motor is of $\frac{1}{4}$th h.p. and drives a 12in. fan at 1,600 revolutions.

Appointments.—The third mathematical mastership at Merchant Venturers' School, Bristol, is vacant—£120 a year and share of fees. Application to G. H. Pope, Merchants' Hall, Bristol, by 22nd. Teachers in mathematics, magnetism and electricity, elementary physics, Spanish and lecturer on experimental general science, are wanted for the Bootle Technical School. The Staffordshire Educational Committee require a lecturer on mining; salary £250.

Prices at Chicago.—The following is the statement sent out to consular officers by the Director-General with reference to pricing of exhibits at Chicago: "Foreign exhibitors in the World's Columbian Exposition will be permitted to state upon placards attached to their exhibits the price at which said products will be sold at the place of manufacture, and also the prices in bond and out of bond, or exclusive and inclusive of the customs duties in Chicago.

Progress of Electric Light in London.—We notice the following installations are being put in by Messrs. Drake and Gorham, pointing to the fact that the necessity of paying a fair price for good work is being recognised by many of the leading offices: The London Assurance Corporation, Royal Exchange (with 180 lights), the Law Union Fire Offices, Chancery-lane, the Credit Lyonnais, Charing Cross, and the Bank of Egypt, Old Broad-street.

City Lighting Company.—Mr. G. H. Nisbett and Mr. F. H. Jackson have been appointed respectively second and third engineer to the company. Mr. Nisbett was formerly with Messrs Paterson and Cooper, and Mr Jackson was out-door superintendent to Messrs. Willans and Robinson, and until recently they were both members of the staff of Major-General Webber, late chief engineer to this company, the former being chief assistant and the latter station engineer.

Wigan.—The Town Council of Wigan are determined to take the bull by the horns, and introduce the electric light at a stroke. Convinced by a visit to Bradford of the possibility of the success of the light at a charge of 6d or even 5d. a unit, they have decided to issue circulars asking, as at Bradford, for customers who will bind themselves for three years, and to undertake the supply as soon as possible. Their provisional order expires in August, unless the work is commenced.

report will be submitted as to the probable cost and most convenient areas to be lighted.

Communication to Lightships.—The Royal Commission on electrical communication between lightships and lighthouses and the shore, held on Tuesday its first regular meeting in Northumberland-avenue, London, the Earl of Mount Edgcumbe presiding. Sir George Nares, Sir Leopold M'Clintock, Mr. F. Bedwell (hydrographer to the Telegraph Construction and Maintenance Company), and Mr. Scott (secretary to the Meteorological Council) gave evidence at considerable length. The Commission examined models showing the swivel mode of attachment to the "Sunk" lightship, and inspected charts showing the number of casualties and of lives lost at various points on the coast of the United Kingdom. A second meeting was held on Wednesday, special attention being given to those lighthouses which have not at present any proper means of communicating news of a wreck or of a vessel in distress.

Yarmouth.—The electric lighting question is becoming a pressing one in Yarmouth, but the Corporation is desirous of not proceeding too fast. The Electric Lighting Committee reported at last Town Council meeting that they had issued conditions and instructions for an installation, the tenders being required by July 28th. They further reported that a tender, with specification, had been received from Messrs. Crossley Bros., offering to fix a dynamo and apparatus for running an electric light installation from the engine now employed for pumping sea-water, and providing 20 50-c.p. lamps on the Marine Parade for a sum of £250 a year. The committee have not accepted the offer, preferring to wait for the advice of Mr. Preece, with whom they have opened negotiations, with the view of securing his services in helping to settle upon the best scheme for lighting after the tenders have been opened. The committee's report was adopted without discussion.

St. Helens.—The St. Helens Town Hall was on Monday lighted up electrically for the first time. There are a total of 338 16-c.p. lamps, of which the assembly-room has three 40-light gasoliers adapted to electroliers. The Council-chamber has 10 three-light polished brass pendants, and in the reading room the coolness is much appreciated. The cost of the new fixtures has been £1,500, and it is calculated that the expense of working it will only be about two-thirds that of gas. The electrical plant for generating the electricity has been supplied by Messrs. Bumstead and Chandler, Hednesford. The wiring was carried out by Messrs. J. D. F. Andrews and Co., under their resident engineer, Mr. J. D. Bailey, and has been superintended for the consulting engineer, Mr. W. Holmes, M.I.C.E., by Mr. C. H. Yeaman, engineer to the Prescot Electric Lighting Company. The specifications were prepared by the borough engineer.

Electricity for Railways.—Amongst the talk for and against the prospects of electric traction for long railways, the following explicit reply to an interviewer from Mr. G. Westinghouse, jun., is distinctly interesting: "As to the operation of standard-gauge roads by electricity in place of the present steam locomotive, such talk is all moonshine. It is a question of centralising the power economically. Now, the present locomotives have nearly the full efficiency of a stationary steam engine and boiler. To put in its place an electric motor connected by structure with a steam plant corresponding to an aggregate of all your steam-boiler plants on wheels would be really duplicating your power equipment with but little advantage and no economies, while there is a reduced efficiency by reason of the transmutation of the heat units from the coal through dynamos and wires to an electric motor on wheels. In the present stage of electrical science, talk of the operation of standard-gauge roads throughout the country by electric traction is wholly visionary."

Douglas.—By the enterprise of the Douglas Grand Hotel, Theatre, and Baths Company, formed last year for the purchase of an extensive block of buildings fronting the Promenade at Douglas, a very effective system of electric lighting of the hotel and baths has been inaugurated. The plant and installation have been supplied by the Brush Company. The principal rooms of The Grand Hotel have been fitted up with incandescent lights; the baths adjoining are supplied with both incandescent and arc lights, while the outside of the building is illuminated with arc lamps. The largest of the two sea water swimming-baths has been altered and rearranged, so as to be available for entertainments; and seats are provided for about 1,000 spectators. During the season daily performances will be given of an amusing nature; while the exhibitions of feats of skill and endurance will also be a feature. The great advantages of the electric light will be here much appreciated, for, while the interior of the building is lighted by arc lamps, there is also an arrangement of incandescent lamps underneath the water to enable the spectators to clearly observe all the actors when they are in the water.

Leamington.—Matters electrical do not seem able to go smoothly in this delightful watering place. There is one thing, however, the Leamingtonians—at least, the hotel portion of them—know how to do, and that is in busy times multiply ordinary charges by three, as they did during the Agricultural Show. But that is not electrical. At the last meeting of the Council, the Midland Electric Light and Power Company, Limited, wrote stating that on Saturday, June 14, they discovered that one of the Corporation water-pipes, which was in a bad and neglected condition, had rusted through and was leaking into the trench containing the electric light cables. This had evidently been going on for some weeks, as all the cables, nine in number, in that part of the trench were considerably damaged, and one of the most important ones corroded right through. The severing of this latter had caused considerable inconvenience and expense in remedying the defect in the supply of electric current. The Council were not very much impressed with this letter, one councillor stating that the company had only themselves to blame in the matter, though why this should be so was not clear.

Heckmondwike.—At the last meeting of the Heckmondwike Local Board the Electric Lighting Committee recommended the Board to take the necessary steps for constructing electric arc lighting plant. The committee visit Loughborough, not at the Board's expense, to inspect the system of electric lighting there. The scheme has been prepared under the direction of Mr. Hutchinson, C.E., embodying overhead system with both arc and incandescent lights. The scheme stipulates for three sets of compound engines and dynamos, of which two sets only are required for an output of 1,000 lights, one set being kept in reserve, and two boilers are provided. The output will be equal to 1,500 16-c.p. lights, and as more lights are added, in similar proportion will the cost of the plant and the annual working expenses be reduced. The light in the Market-place would be ten times as effective as at present at about the same cost. The committee are hopeful as to a demand for the light by shopkeepers and others. The estimate of the cost shows the initial outlay to reach about £4,450, whilst interest, depreciation, and maintenance are put down at £1,048 per year. The estimated annual revenue is £1,432.

Fire Alarm Telephones.—In an interesting note published some time at the beginning of the year the chief of

the Metropolitan Fire Brigade notified to the citizens of London that care should be taken not to trouble the brigade with false alarms. We were told that quite a large proportion of the fire alarms received by the brigade were false alarms—mischievous and otherwise. This constitutes a serious difficulty in the way of the action of the brigades, as it not only involves turn-outs and loss of time and temper, but it may well happen that a true alarm may follow and the engines are away on a bootless errand. The application of the telephone to fire alarm posts promises to obviate this defect in the system. Paris has already adopted the telephonic alarms for the "Sapeur-Pompiers." Instead of breaking a glass and pulling a handle merely (and sometimes running away), the person who advises a fire breaks a seal, opens the door and shouts in the opening of the telephone receiver "Fire, Smith-street, No. 20," or other detail, until a fanfare of trumpet or bell advises him the engines have started. In *Les Inventions Modernes* for July 20 (4, rue Chaussée-Antin, Paris), the whole arrangement is described and very fully illustrated. The apparatus is supplied by the Société Générale des Téléphones, 41, rue Caumartin, Paris. It seems that private persons can have the telephone alarms fixed on their own premises at a moderate cost.

Mine Surveying. — Some interesting and amusing information is given in the Cantor lectures by Bennett H. Brough, published in the *Journal* of the Society of Arts, of the use of the magnetic needle in mine surveying. The needle, says Mr. Brough, has been largely used in Sweden and in the United States. The theory of its use is based on the fact that certain ores become magnetic by induction under the influence of the earth's magnetism. By noting the dip of the magnetic needle the extent of the iron deposit can be ascertained. Prof. Le Neve Foster mentions the case of an iron deposit in Sweden being mapped out by observations on the ice. Compass explorations being in many instances a source of income, a skilful operator often wishes to keep his mode of procedure a secret, and the supposed supernatural properties of the divining-rod are transferred to the compass. Unfortunately, the compass is admirably adapted for dishonest purposes. The case is recorded of an American prospector whose compass needle, in the vicinity of an ore mass, always showed a dip of 90deg. when facing west, and the true dip due to local attraction when facing east. The former position was successfully used in selling and the latter in buying the iron ore ground. In Sweden a magnet in the walking-stick has been successfully employed to give a large dip when it was thought advisable to mislead the purchaser. Of late years, purely scientific methods of exploring for iron ore with the magnetic needle have been introduced, and in this way important deposits have been discovered in Sweden; whilst in New Jersey, in six years, the annual production has increased 50 per cent. by the addition of new producing localities found by the compass.

Garden Party.—Lauriston, Mr. J. W. Swan's residence in the pretty town of Bromley, Kent, was the scene of a brilliant assembly at Mrs. Swan's garden party on Thursday last week. Visitors are always favoured with a singularly happy combination of musical and artistic charm with scientific novelty, and the present was no exception. Max Hambourg, the Russian musical boy prodigy of 13, discoursed deftly and masterfully the music of Liszt, and other difficult composers, under the admiring gaze of Mrs. Swan's friends, amongst whom were Dr. and Mrs. S. P. Thompson, Dr. Dallinger (the eminent entomologist and divine, and his wife), Prof. Elisha Gray, with Mr. W. J. Johnston, from America, Mr. Percy Bigland (the painter of Mr. Gladstone's portrait) and his wife—late Miss Aggs—a noted lady traveller; together with many electrical and other celebrities. Miss Dora Tulloch gave some admirable recitations, and a marvellous silhouettist was only prevented from exhibiting his skill by sudden illness. In Mr. Swan's laboratory the scientifically inclined saw the process of electro-deposition of copper, recently described before the Royal Institution, in actual work. Large slabs were being deposited in a rocking bath of special solution, driven by an electric motor, and specimen anodes and cathodes were shown. A thin strip of perfectly coherent and brilliant copper was deposited before visitors' eyes in two minutes only. But the most interesting, perhaps, was the wire deposition. A long trough of solution contained a wire, which was being drawn backwards and forwards through sapphire dies. Deposition occurred, but as the diameter of the wire was always kept the same by the dies, the length, of course, grew, and a wire of any length might thus be obtained by direct deposition. It was curious to examine the cross-section of such a wire under the microscope, when the original core had nearly disappeared under successive layers. The quickness of the deposition (fifty or a hundred times that of ordinary processes) is, of course, the great advantage of Mr. Swan's process, the exhibition of which created a great deal of interest.

Amsterdam.—As early as 1888 a small installation of 231 kilowatts, supplying 2,000 16-c.p. lamps, was established in Amsterdam. Of this, 156 kilowatts was continuous current at 65 volts, distributed on overhead wires; and 75 kilowatts in alternating 2,000-volt current, distributed in underground concentric mains of a total length of about two miles. In 1890 the Electra Society, who owned this installation, obtained a 28 years' concession for lighting the town. To comply with the conditions determined upon, a new station was opened on the 28th of May last for alternating-current system alone. The station is situated about a mile from the town, and contains eight multitubular MacNicol boilers, each of 153 square metres heating surface. Three horizontal steam engines of 700 h.p. are used, of the type shown at Frankfort by the Helios Company, of Cologne, each driving a Ganz alternating dynamo, giving at 195 revolutions 400 kilowatts at 2,000 volts, at a frequency of 50 periods per second; also an exciter of 20 kilowatts of 65 to 100 volts. A fourth set, same type, of 200 h.p. produces 150 kilowatts; and a fifth consists of a vertical Dingler engine of 160 h.p., developing 75 kilowatts. This latter is the engine that used to drive the old station, which is being given up. The total power is 2,260 h.p., or 1,500 kilowatts. All are condensing engines. The current is distributed by Felten and Guilleaume concentric lead-covered cables, armoured and served with an outing coating of hemp. The cable is laid in wood troughs, filled in with asphalte and covered in with brick. Cast-iron boxes are used for distribution; a length of 20 kilometres, or 32 miles, has already been laid. The transformers are of closed-circuit type, by Ganz and Co., transforming from 2,000 down to 72 or 36 volts. The 72-volt circuit is used for arc lamps, which are run two in series on this voltage. The current is supplied at 46 cents per kilowatt-hour—say 9½d. a unit. Consumers taking a supply of over 750 hours a year have a 30 per cent. reduction. Frager and Ganz meters are both used, and each installation pays a certain annual charge besides for service, according to its size. There are 6,100 lamps of 16 c.p. at present being supplied. These particulars are taken from the *Bulletin Internationale de l'Electricité*, a journal always full of crisp and useful information of electrical matters on the Continent.

ANNUAL MEETING OF MUNICIPAL AND COUNTY ENGINEERS.

The annual meeting of this society commenced at Bury yesterday, and will be continued to-morrow. Mr. J. Cartwright, borough engineer of Bury, presided. There were one or two papers of interest to electrical engineers—that of Mr. Cox, relating to tramways, and that of Dr. Burghardt, to sewage precipitation by electricity. We give Mr. Cox's paper in full, and such portions of Dr Burghardt's as relate to electricity. Besides papers, a number of visits were arranged, those to the mills of Messrs. Musgrave and Co., and to the works of Messrs. Mather and Platt being of interest to our readers—the former because of the mills being electrically lighted, the latter because the firm is one engaged in manufacturing electrical apparatus.

Street Tramways and Electric Traction.

BY J. H. COX, M.I.C.E.

The first tramway in England was laid by Mr. G. F. Train in 1860, at Birkenhead, by permission of the Birkenhead Commissioners, but it was not viewed with much favour by the public, and therefore it was not until 1868 that an Act of Parliament was obtained authorising the construction at Liverpool of the first English system of street tramways for passenger traffic. Since that date they have spread very rapidly all over the country, until the total length has reached over 1,000 miles, representing an invested capital of more than 14 millions.

Many different systems of tram rails have been adopted, the earlier lines being laid with light wrought-iron rails on longitudinal or transverse wood sleepers. The cars at first were all drawn by horses, but as steam engines became introduced about 1876, engineers were compelled to construct the permanent way in a more substantial manner. Wood sleepers were discarded for metallic ways, and iron rails were superseded by steel. Steam engines have done good service on tramways, especially in those towns where the gradients are too steep to be worked by horse power, but they are very destructive to the permanent way and are not entirely free from other objections, such as noise, smoke, steam, dust, and smell. It should not be forgotten that steam engines have not only to haul the heavy cars and passengers up these hills, but they have their own ponderous weight to drag up likewise, and on the downward journey the everlasting jerks when the brake is applied are a source of damage both to the engines and the permanent way.

It may be interesting to some of you to have the figures showing the cost of maintenance for the Manchester-road tramway in Bradford, which has been worked by steam power for the last seven years. The rails are of steel, 7in. deep, girder pattern, weighing 103lb. to the yard, laid on concrete foundation, and the road is paved with granite setts from kerb to kerb. The line is 2 miles 16 yards in length, 1 mile 789 yards being double line, and 987 yards single line. Line opened September 5, 1884.

					Per mile of single line.		
1884.*	Cost of maintenance,	rails,	and	paving	£2	12	4
1885	"	"	"	"	8	14	10
1886	"	"	"	"	17	3	8

1890.	"	"	"	"	55	18	2

* Three months only.

The actual wear caused by a 10 minutes' service of cars on the tread of the rail up to the present time is $\frac{3}{16}$in. on the single line, and practically the same on the double portion. The engines are Green's, and weigh 12 tons. The bogie cars carry 68 passengers, and weigh eight tons when loaded with passengers.

The excessive cost of maintaining tramways worked by steam has caused many tramway authorities to look in the direction of cable haulage and electricity for deliverance from their troubles, and under suitable circumstances these modes of traction have already proved very successful. Those members of this association who attended the district meeting in Edinburgh in the autumn of 1890 saw a capital example of the cable system in operation in that city, and they were also favoured with a most interesting paper on the subject by Mr. Colam, the engineer. There is no need to repeat to an audience like this the many advantages which may reasonably be urged in favour of the cable system when applied to tram routes with severe gradients in populous districts which are able to support a very rapid service of cars; but there are very few tram routes, except in the largest towns, which can maintain a five minutes service, which is necessary to make cable haulage a complete success. The Bradford Corporation were reluctantly compelled to drop the idea of introducing this system into Bradford for the projected tramway in the Wakefield road district, mainly because of the difficulty of keeping up a rapid service of cars, and enquiries were therefore started as to the cost and capabilities of electricy as a motive power for working tramways on steep gradients.

Electric traction, as you know, has made wonderful strides since Dr. Siemens laid the first electric tramway at Berlin. Only one decade has passed since then, and now upwards of 3,000 miles of lines are worked by electricity in America alone. Our American cousins appear to live and move at a high-pressure rate, and do not stick at forming a network of wires over their streets, so long as it facilitates locomotion; but in Europe we proceed more cautiously, and there is little doubt that these objectionable overhead wires have considerably interfered with the progress of electric traction on this side of the Atlantic. With electricity as a motive power, we have the choice of the proverbial three courses: First, to work by means of storage batteries placed under the car seats, as at Birmingham; secondly, by the underground system; and, thirdly, by overhead conductors.

As to the first, or storage system, we have a splendid example at Birmingham, which, by the courtesy of the chief engineer, Mr. Dickinson, I had the pleasure of inspecting some 18 months ago, soon after its opening. To my mind it is an ideal system, and I sincerely hope it may some day supersede both the underground and overhead methods, but, unfortunately, there is at present little hope of such a consummation—at any rate, on gradients such as exist in Bradford. On level routes it is a system even now well worthy of consideration, and although it may be more costly to work than the overhead and conduit systems, yet it has many advantages over its rivals, such as the cars being able to run quite independently of each other, and independently of either overhead or underground wires, thus freeing the streets of many objectionable obstructions. It has many other advantages that I need scarcely recount to a meeting like this—not the least of which is its freedom from one serious drawback of the direct system—viz., where a breakdown of the principal machinery at the power station causes a temporary stoppage of the entire system.

Unfortunately, there are some disadvantages, the two most serious being the great weight of the batteries, which, at Birmingham, on a comparatively level line, amounts to 4,800lb., or 2 tons and 3 cwt.; this, added to the weight of car and motor, making $8\frac{1}{2}$ tons for a car carrying 50 passengers. Another serious disadvantage is the deterioration of the batteries; and although some progress has been made within the last year or two in making the plates more durable and reducing the weight, there is still much room for improvement.

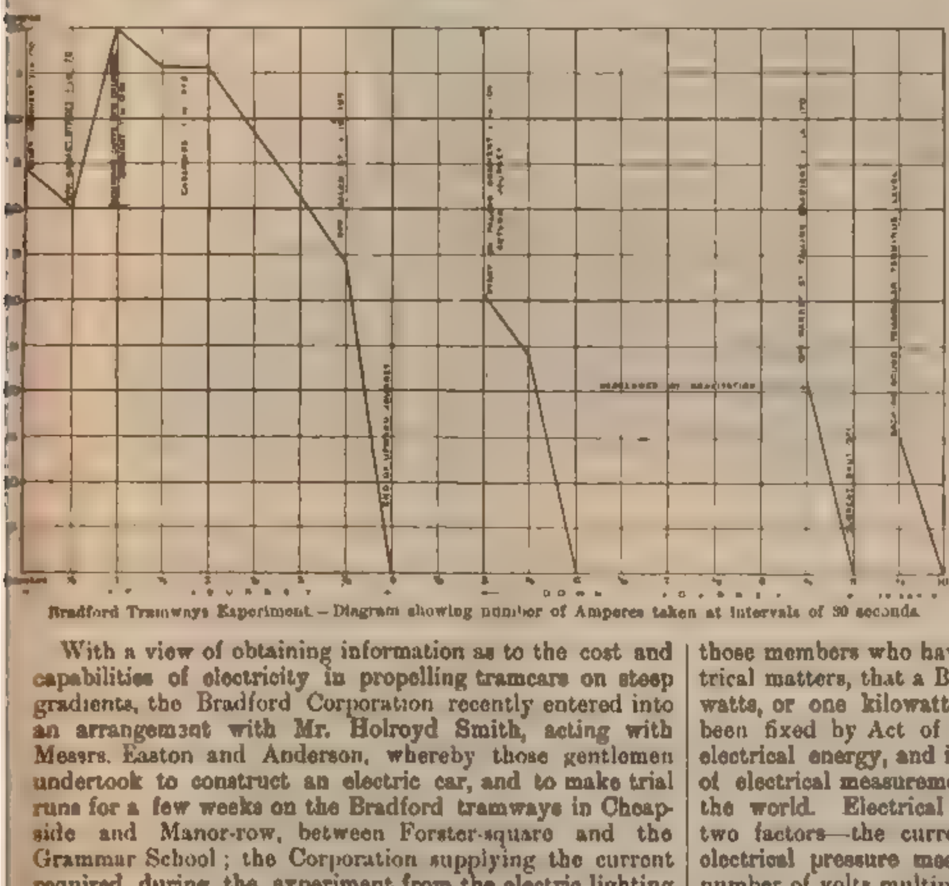
It is therefore necessary to turn to the direct system, where we have the choice of two methods—the underground or conduit system, or that of overhead wires. It is true there are several ingenious contrivances which may be included under the head of surface methods with electro-magnets attached to the car, but they have scarcely yet passed the experimental stage, and at present are certainly not practicable for hill climbing. The underground system, which has been for six years in operation at Blackpool, has proved fairly successful, in spite of the difficulty caused by the sand blowing into the conduit from the shore, and occasional flooding by sea water during storms, and by exceptionally high tides. In America this system has made very little progress, partly because of its extra cost, but mainly on account of the difficulty in preventing the conduit becoming filled with mud and water. This rather points to imperfect sewerage systems, and should not apply

to a well-drained town, where frequent connections would be made between the conduit and main sewer. An inland town would, of course, be free from sea-water and sand, and so long as the main sewers do not become overcharged during thunderstorms and heavy rains, I see no great reason why the conduit arrangement should not answer. Like the other systems, it is not free from disadvantages, but no doubt its large additional first cost and the drainage difficulty have been the chief factors in preventing its adoption to a greater extent in America.

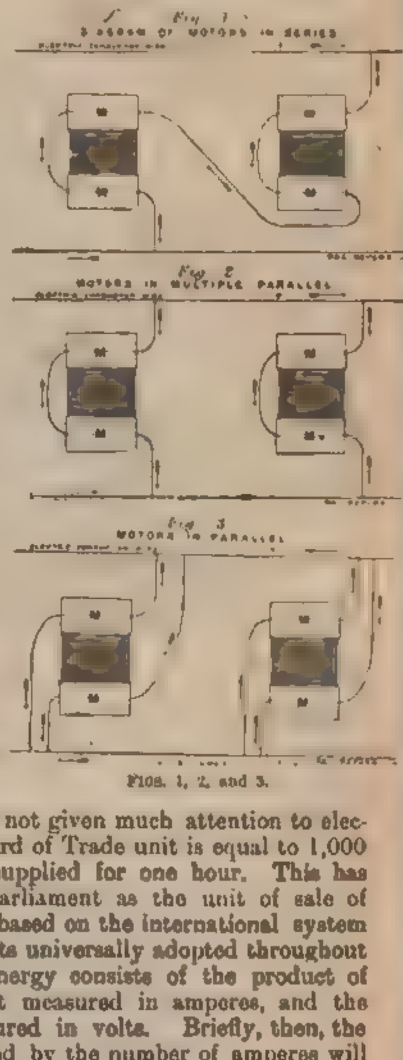
Finally, we come to the overhead system. On this side of the Atlantic there is no doubt a prejudice—or, to put it more mildly, a very strong objection, against allowing posts and wires to be erected in and over our streets; not only on account of disfigurement and obstruction, but also from fear of accident. On the latter score there is evidently little ground for misgiving, seeing that no fatal, or even serious, accident has occurred yet. As regards the disfigurement of the streets caused by the posts, no doubt it is possible to reduce the objection to some extent by using suitable ornamental iron posts; but as obstructions they will, I fear, be more apparent in our streets than in some continental cities, where they are to a great extent hidden by the long avenues of trees which line the edges of the footwalks. In many such cases the poles support lamps for lighting the road by electricity. Personally I should welcome either the conduit or overhead systems, if they would deliver us from steam haulage.

time per journey down, 3·73 minutes = six miles per hour; quickest journey up, when motors were worked in parallel, 2·00 minutes = 11 miles per hour; slowest journey up, 5·00 minutes = 4½ miles per hour. Total measurement of electricity used during the 13 days' run, 240 Board of Trade units. Average per mile run, 1·52 unit, say, 1½. Therefore, taking an average throughout the entire trial, the car required for its propulsion 2 e.h.p. hours per mile run. Cost per mile run for electricity, assuming the price to be 2½d. per Board of Trade unit, 3·81 pence. The price of 2½d. has been fixed by the Gas and Electricity Committee of the Bradford Corporation, and I am of opinion that they could afford to supply the current at 2d. per unit, a price which would not only pay for the generation of the electricity, but leave a sufficient margin to cover establishment and other charges. I may mention that only last week a private firm of engineers, having their works situate about half-way on the Wakefield-road route, offered to supply the current at 2d. per Board of Trade unit.

It may be as well to explain briefly, for the benefit of



Bradford Tramways Experiment.—Diagram showing number of Amperes taken at intervals of 30 seconds.



FIGS. 1, 2, and 3.

With a view of obtaining information as to the cost and capabilities of electricity in propelling tramcars on steep gradients, the Bradford Corporation recently entered into an arrangement with Mr. Holroyd Smith, acting with Messrs. Easton and Anderson, whereby those gentlemen undertook to construct an electric car, and to make trial runs for a few weeks on the Bradford tramways in Cheapside and Manor-row, between Forster-square and the Grammar School; the Corporation supplying the current required during the experiment from the electric lighting station, by means of overhead conductors, at a pressure of 300 volts. The length of the trial run is 660 yards, commencing with a tolerably level inclination of 1 in 340 for 100 yards, then curving into Cheapside on a gradient of 1 in 13·22 with a radius of 64ft. 6in., followed by a straight inclination of 1 in 14·75 for 193 yards, 1 in 20 for 137 yards, and terminating at the end of a comparatively level gradient of 1 in 104 for 160 yards. The total rise is 70½ft. or an average inclination of 1 in 28. The Wakefield-road route is even steeper than this, having a total rise of 352ft. from the Town Hall to Rooley-lane, a distance of 2,830 yards, or an average of 1 in 24. The experimental running began on the 16th of May and terminated on June 9. The car only ran on 13 days, and made 204 return journeys, or a total mileage, including the triangle at Forster-square, of 157½. Average time per journey up, 3·79 minutes = six miles per hour; average

those members who have not given much attention to electrical matters, that a Board of Trade unit is equal to 1,000 watts, or one kilowatt supplied for one hour. This has been fixed by Act of Parliament as the unit of sale of electrical energy, and is based on the international system of electrical measurements universally adopted throughout the world. Electrical energy consists of the product of two factors—the current measured in amperes, and the electrical pressure measured in volts. Briefly, then, the number of volts multiplied by the number of amperes will give the watts, and the watts divided by 746 will give the horse-power. A Board of Trade unit being equal to 1,000 watts supplied for one hour, is also equal to about 1⅓ h.p.

The number of passengers carried up was 1,321, or 6·4 persons per journey; passengers carried down, 912, or 4·5 persons per journey; greatest number of passengers carried up on one journey, 44; greatest number of passengers carried down on one journey, 38. The driver and conductor are not included in the above figures. The car has been stopped and started again on the steepest gradients without difficulty, even when fully loaded with passengers, and has taken the curve at the bottom of Cheapside without any preliminary rush. The E.M.F. has only varied very slightly, from about 280 to 300 volts. On several of the ascending journeys the voltmeter and ammeter carried in the car gave the following readings at various places on the route.

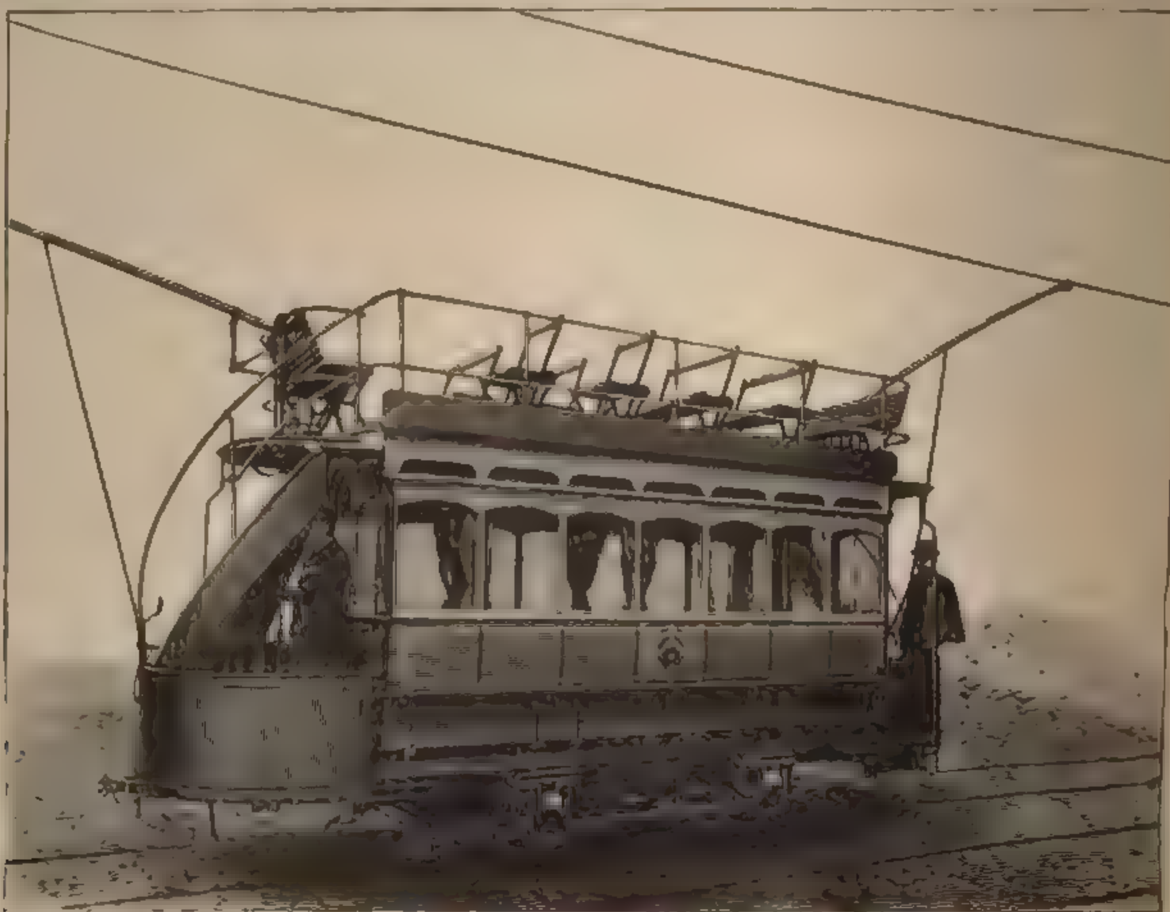
	Volts.	Amps.	E H P.	Gradient.
Opposite the end of Market street	294	40 =	15·76	1 in 170
Rounding curve into Cheapside	280	60 =	22·52	1 in 13·22
Half way up Cheapside	281	56 =	21·09	1 in 14·75
Opposite Salem street	281	34 =	12·80	1 in 85

On the descending journey :

Opposite Savings Bank	294	24 =	9·45	1 in 104
Rounding triangle, Forster-square	300	14	5·63	level

The momentary current required to start the car on the steep gradient in Cheapside was about 100 amperes. The dual armature motors may be set to work in series (see Fig. 1) which gives a slow speed of, say, four miles per hour; in multiple parallel, Fig. 2, which gives a moderate speed uphill of six to seven miles per hour; or in parallel, Fig. 3, a speed of 11 miles per hour.

During the trial some hitches occurred from various causes, occasioning delay; but nothing really serious happened to raise much doubt as to the ultimate success of the experiment. The motors at first produced a slight hissing sound, but this was soon remedied, and the running



Car built by Messrs. Easton and Anderson for the Bradford Electric Tramways.

car will seat 36 passengers, 18 in and 18 out, and weighs 3 tons 9cwt. 2qrs. The motor truck and motors weigh 3 tons 19cwt. 2qrs., total, say, 6½ tons; when fully loaded with passengers the total weight may be taken at 8½ tons. Dual armature motors of 15 h.p. each transmit motion to the wheels by means of worm gearing, and the of the motors and gearing afterwards was practically noiseless. An electric brake is available, so arranged that when the car is running downhill by gravitation alone it drives the motors, and they can be instantly set to act as dynamos generating a current that tends to drive them in a reverse direction, and so stops the car.

Motor Truck used on the Bradford Electric Tramways.

worm wheels are so attached that each car wheel is separately driven, each axle having only one wheel keyed upon it, the other being keyed upon a loose sleeve conjointly with a worm wheel. The electricity is controlled by three switches at each end of the car—one a main supply or emergency switch, one a regulating switch acting upon resistance coils, and one a setting switch whereby the two

Although a few mishaps occurred, as above stated, it has been clearly shown that the motors are amply powerful to work steep gradients. The car runs very smoothly, without making much noise or nuisance of any kind, and causes considerably less damage to the permanent way than the heavy steam engines and cars at present in use.

The net results, then, of the recent experiments is

electric traction at Bradford show that cars worked by electricity can be made to mount any gradient which can be climbed by a steam engine, and quite as cheaply, providing there is a tolerably quick service and plenty of traffic; that the energy required to ascend and descend such gradients, as I have mentioned, is 1½ Board of Trade unit per mile, and assuming the price of the electricity to be 2d. per unit, it follows that the cost of running up and down such gradients is 3d. per car mile.

As the primary object of the experiment was to ascertain the desirability or otherwise of adopting electricity for working the projected steep line in Wakefield-road, perhaps I may be permitted to state as briefly as possible the conclusions which I arrived at. The length of the proposed tramway route for Wakefield-road is 2¼ miles. The carriageway at present is not sufficiently wide to admit of the construction of a double line, and, if specially widened for the purpose, it would involve the narrowing of the footways to the extent of about 2ft. on each side of the road, at an expenditure of £1,600. A double line of ordinary tramway would cost £4,500 more than a single line with passing places, besides an additional cost of £3,150 for a double underground conduit.

There are also other advantages in favour of a single line—viz.: There is less interference with the roadway and ordinary traffic, less length of line to maintain, less rental for the lessees to pay, and experience has proved that the wear of a single line is very little, if any, more than that of a double line. This may appear somewhat strange, seeing that there is twice the amount of traffic passing over the single portions of the line that passes over the double portions; but the joints of a tramway are always the weakest places, and on a double line the heavy engines and cars are constantly travelling in one direction, which tends to beat or hammer down the leading end of each rail, thus causing serious damage both to the rail, fishplates, and concrete foundation at each joint, whereas on the single line the traffic passing in both directions compensates matters by pressing equally on both rail ends. Formerly there was some difficulty experienced in working a single line, and passing places with the electric and cable systems of traction, but such improvements have been made in the points and crossings that no serious difficulty need be apprehended in this respect. The estimates are based on a 15 minutes' service, which gives 80,000 car miles per annum.

WAKEFIELD-ROAD TRAMWAY.

Electric traction: Approximate estimate of working expenses, at per car mile, in pence.

Electrical energy	3·812	per car mile.
Wages of drivers and conductors	2·000	,,
Repairs to motors, etc.	1·000	,,
Repairs to cars	0·200	,,
Depreciation on rolling-stock	1·300	,,
Water and gas	0·250	,,
Rates and taxes	0·650	,,
Maintenance of electric conductor	0·345	,,
Compensation for damages	0·250	,,
Stationery	0·070	,,
Salaries	0·858	,,
For 80,000 car miles	10·735	

Owing to such a small car mileage as would be attained with the present limited passenger demand, the expenses work out exceedingly high, and it is quite hopeless to expect electric traction paying on a short isolated line like Wakefield-road, unless a much quicker service can be maintained with at least double the above number of car miles annually.

The working expenses, which I estimate at 10¾d. per car mile run, exclusive of rental,* would decrease rapidly in proportion to the number of miles run. For instance, for another line in Bradford—viz., Manchester-road tramway—having a yearly car mileage of 175,000, the rate for working expenses and rent would probably be reduced to 9d. Again, the receipts on this line are very high—viz., about 16d. per mile run—whereas on the Wakefield-road line they cannot safely be estimated to reach more than 11d. or 1s. per car mile. The following statement, marked A, gives a summary of the capital expenditure. Statement B shows the approximate annual working expenses.

*Conduit system, rental 3·31 pence per car mile additional—viz., 14d.
Overhead ,, ,, 2·46 ,, ,, ,, ,, 13¼d.

WAKEFIELD-ROAD TRAMWAY.—A.
Capital Expenditure.—Summary.

Description.	Permanent way.	Electrical work.	Widening carriage-way.	Main supply cable.	Total.	Equipment by lessees.
	£	£	£	£	£	£
Double line throughout, overhead conductor	16,200	3,190	1,611	750	21,751	8,900
Single line, overhead conductor	11,700	3,190	nil	750	15,640	8,900
Double line, conduit system	16,200	11,340	1,611	750	29,901	8,900
Single line, conduit system	11,700	8,590	nil	750	21,040	8,900
Steam traction, single line	11,700	nil	nil	nil	11,700	11,850

WAKEFIELD-ROAD TRAMWAY.—B.
Annual Working Expenses.—Summary.

Description.	Annual working expenses.	Annual rental.	Total.	Receipts.	Surplus.	Deficit.	Equipment by lessees.
	£	£	£	£	£	£	£
Electric overhead conductor	3,578	821	4,399	4,000	—	399	8,900
Electric conduit system	3,578	1,104	4,682	4,000	—	682	8,900

It is therefore certain that electric traction cannot be adopted for the Wakefield-road line so as to be self-supporting, the loss in case of an electric tramway with overhead conductor being £400 per annum, irrespective of the interest on the capital sum of £8,900 which would have to be spent by the lessees on the equipment of the line. This latter sum, taken at 5 per cent., would therefore make the total loss £845 per annum.

The loss upon an electric tramway with underground conductor would be still more, owing to the greater first cost of the line. The deficit in this case is estimated at £682, which, added to the interest at 5 per cent. on the sum of £8,900 for equipment, gives a total loss per annum of £1,127.

Seeing that two tramway companies already exist in the town, both employing steam as a motive power, the most economical course would undoubtedly be to let the line, if possible, to one of them, as the capital charges and working expenses would be considerably reduced in their case, than if leased to a new company or promoters.

The question I have therefore put to the Corporation is: Will they adopt steam traction for the Wakefield-road section for the unexpired portion of the lease which has now nearly 11 years to run; in the meantime gaining experience by observing the results of electric traction in other places? or, will they subsidise the tramway to the extent of the loss mentioned, and try electric traction for the remainder of the lease, and thus obtain reliable data, which may enable them to decide as to the motive power to be used on all the Corporation tramways when the existing leases have expired in 1903?

Sewage and its Purification.

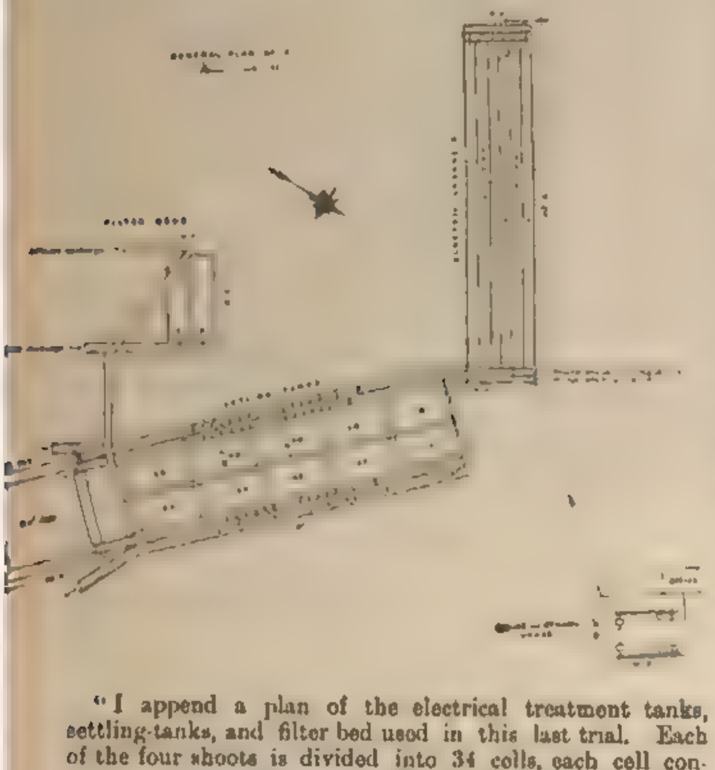
BY CHAS. A. BURGHARDT, PH.D., ETC.

(Abstract.)

We have recently called attention to what seems to be a wide field for the use of electricity, and to-day a paper by Dr. C. A. Burghardt has been read before the Municipal and County Engineers, the electrical portions of which we are able to give. After discussing various other processes, Dr. Burghardt goes on to say—

"The next process in which iron plays the part of purifier is the electrical purification process also described in the above-mentioned report. Briefly, the iron, which is the active agent, is derived from iron plates placed in cells through which the sewage constantly flows. The iron plates are so arranged that on passing an electric current through the series of cells one set are positive and the other negative. Only the positive plate is acted upon

and dissolved upon its surface, the hydrated ferrous oxide mentioned above being produced by the action of the nascent oxygen (liberated by the decomposition of the water at this pole) acting upon the metallic iron. This hydrated ferrous oxide (which is in solution) then acts upon the organic matter in the manner described above, becoming, firstly, hydrated ferric oxide by absorption of oxygen from the air, giving up this oxygen again to the organic matter and becoming the lower oxide, and repeating this operation for a considerable time until the carbonaceous matters which are oxidisable have been oxidised, when no further reduction of the ferric hydrate can take place and it remains insoluble and suspended in the effluent, as a yellowish precipitate. In order to cause the plates to wear off or dissolve equally, the poles are reversed on alternate days, a plate being positive one day and negative on another day. Since the issue of the Salford sewage treatment report in 1890, the electrical process has been submitted to a thorough trial, at Weaste, from October, 1891, to March, 1892, on a specified quantity of 4,167 gallons per hour, or 100,000 gallons per 24 hours. The current density employed was one ampere for every seven square feet of electrode surface, or 0·4 ampere-hour per gallon of treated sewage. The electric shoots or channels were constructed in four lengths—the smallest number which would be adopted in practice.



"I append a plan of the electrical treatment tanks, settling-tanks, and filter bed used in this last trial. Each of the four shoots is divided into 34 cells, each cell containing 16 iron plates each 2ft. by 1ft. 6in. by ½in. The total weight of iron plates employed in this trial was about 55 tons. The plates were connected all parallel in each cell, the cells in each shoot connected in series, and the four shoots parallel. The electrical energy employed was 50 amperes at a pressure of 50 volts, or a little over 4 i.h.p. Each of the shoots was connected by conductors with a distribution board and suitable switches in the engine-house, in order to enable the operator to reverse the current of any one shoot when desirable. This reversal of the current was carried out upon one shoot at a time, the other three shoots taking temporarily the whole flow of the sewage. The poles of the shoot in question being reversed, the cells in that shoot were short-circuited, which at once caused a very rapid discharge of the back current. After this had taken place the current was reapplied in the opposite direction through a resistance coil, and the resistance gradually cut out as the normal electrical conditions were established. This is, of course, an easy matter for anyone having the most elementary knowledge of electrical matters, and should present no difficulty in practice. The treated sewage then flows into the 10 settling tanks (two sets of five) shown in the plan, each tank being 8ft. wide, 16ft. long, and about 5ft. deep. The sewage flowed continuously through one or other of these sets of five tanks, and over the intermediate walls of each tank, which were provided with double lips in order to assist the oxidation of the effluent. It was found that the production of wet sludge was at the rate of 17·5 tons per million gallons of sewage treated. The suspended matter is principally hydrated ferric oxide, and practically free from organic matter of an objectionable character. The amount of metallic iron used is about three grains per gallon of treated sewage, and nearly all this is present in the sludge as hydrated ferric oxide. Experiments were carried out with this sludge, by burning it under proper conditions, when it was found that a red oxide of iron was obtained which could be converted into a pigment. Possibly this pigment may be so produced in a satisfactory condition and disposed of at a price which will cover the cost of production, and thus get rid of the sludge.*

"The suspended matter was removed by passing the settled effluent over the ordinary sand filter-beds shown in the plan, and it was found that the filters did not become choked at all, but retained their efficiency from October 1891, to the end of the trial in March, 1892. I think that this process has a good future before it, because electrical plant and machinery is being rapidly cheapened and improved every year. From a scientific point of view the process leaves little to be desired.

Visits of Municipal Engineers at Bury.

Among the visits arranged, two were of interest to electrical engineers—viz., to Messrs. Musgrave and Sons mills at Bury, where Messrs. Holmes and Co. have installed the electric light, and to Messrs. Mather and Platt's works at Salford. Although the installation at the mills of Messrs. Musgrave and Sons has been previously described, it may be well to recall it.

The power for driving the dynamos is obtained from two vertical engines, made by Messrs. John Musgrave and Sons, Bolton. The dynamos, two in number, are driven from the engine flywheels by means of cotton ropes. They are of the well-known Castle type, manufactured at Newcastle-on-Tyne, and the latest improvements, both in mechanical and electrical details, are embodied in their design. The output of each dynamo is 46,000 watts, or 62 e.h.p., which is equivalent to lighting 770 16-c.p. lamps; the speed is only 550 revolutions per minute. With slow speed there is less wear and tear on the bearings, commutator, and brushes than with high-speed dynamos. It means an increase in first cost, as the output of a dynamo varies almost directly as the speed. The electrical efficiency of these machines is high—viz., 95 per cent.—and the commercial efficiency is 90 per cent. The dynamos are compound-wound, so that the electrical pressure is the same for any number of lamps that may be burning from about 5 per cent. to the full load. The field magnets of the Castle dynamos are massive and of the best wrought iron obtainable carefully annealed; this secures a very intense magnetic field, which is one of the chief reasons for the high efficiency obtained. The armatures are built up of thin iron discs of the softest Swedish charcoal iron, thoroughly annealed and mounted on carefully-turned gunmetal centres, notches being made in the discs to obtain positive driving. The conductors used on the armature are of high-conductivity copper, drawn and put together in a special manner, by which Messrs. Holmes and Co. claim to get about 20 per cent. more copper into the space than is possible with ordinary methods of winding. The electrical resistance of the armature is much reduced by this method of winding, and this is another reason for the high efficiency obtained. The periphery of the armature is carefully bound with bands of wire to withstand the centrifugal force resulting from rotation. Sight-feed lubricators of the Castle pattern are used. This lubricator consists of a syphon arrangement, and when the drip is once adjusted to the required number per minute it need not be interfered with afterwards, as there

* For the chemical and engineering results obtained from the working of the electrical process, I must refer you to the report of 1891.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE TRAMCAR SERVICE OF GREAT BRITAIN.

We have in this journal done our best for the last two or three years to force the attention of engineers to the vast field that lays ready to their hand in the employment of electric traction on our tramways. We have given great prominence to the description of experimental tracks, to articles upon the adoption of electric locomotion through our streets, to the record of progress on the Continent, and especially in America, where the introduction of electric tramway lines has been one of the most striking events of modern practice. We wish now to emphasise one or two points from the public point of view, which it will be necessary seriously to consider as guiding the policy of the next few years. The signs of the times point at last to a considerable awakening of both the public and the technical and financial directors of tramway enterprise to the advantages of electric traction, and there are several concomitant advantages which may well be wrought out at the time of the promised extension of the new method of traction.

When we look back some eight or ten years to the state of tramway investment, or, as they are termed in the States, street railroads, we find an enormous improvement in the general status of the industry. The stocks of tramway companies were looked upon as a poor sort of investment, hardly worthy of being considered substantial; the byword was one of standing jokes of bob-tailed cars and kicking mules; the cars themselves were dingy, small, slow, and uncomfortable vehicles of travel. When the electric motor appeared on the scene, the early innovators fortunately appreciated the sound nature of the investment they had chosen to revolutionise. They saw indeed that tramways were but railways, and railways under the best of conditions—stopping frequently, passing through crowded residential and business districts, constantly full, and of great carrying capacity in proportion to the outlay for plant. They realised then the need for a complete change in the attitude of the public mind towards tramways. The electric cars which replaced the old horse cars were built on an altogether different model of size and comfort. Well-built handsome cars, clean, airy, luxurious even, took the place of the dingy crawlers. The service was organised on a time-sheet service, the officials were uniformed, and trained to be courteous, clean, and attentive. The combination of handsome cars, quick service, and courteous, uniformed officials has transformed the investment into one of the most solid, the best paying in the market; and street railway stock is now quite as much sought after and pays equally good and substantial dividends as the corresponding railroad companies. Listen to what Mr. Geo. W. Hommell, the manager of the Milwaukee Street Railway, has to say upon this point in a letter recently printed in the *Street Railway Journal*: "When I first came to this city from New York, some four years ago, we had very old-fashioned horse and mule cars, and you can well imagine how odd they looked to me. Our business was comparatively small (so were the cars), but now we have our lines almost completed with

others apply it more widely. Now we are quite sure manufacturers will agree with us when we say that. with only one or two exceptions, electrical apparatus is sold with only the ordinary manufacturing charges added to the prime cost. Take the heavy items, there is no extra charge due to patents on dynamos, motors, or transformers. We are quite sure, from personal knowledge of the manufacture of excellent accumulators, that the charge to the buyer includes but a very small percentage, if any, of the price due to patents. It is a mistake for purchasers to suppose that in this year of grace patents add much to prices quoted. Probably incandescent lamps and meters are the only direction in which patented articles cost more than unpatented articles of a similar character. The incandescent lamp is as yet a monopoly. Its price is probably higher than will be the case when the patents expire. But, after all, the ordinary consumer is not now highly taxed because of patents in this case. Nor is he in the case of a meter, as usually only one meter is required in one house. The grumble of the manufacturer is that prices rule too low, that an ordinary manufacturing profit is hardly attainable; and companies saddled with a capital largely watered through payments for patents cannot pay a moderate dividend, because they cannot increase the charges. We trust that purchasers will soon disabuse their minds of the error. Those with a knowledge of the cost of materials and of engineering work will easily see our contention is correct, and that in few, very few, cases "do they have to pay any patent tax."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard"

ELECTRIC TRACTION.

Sir,—With reference to my paper on "Electric Traction," read before the Tramways Institute of Great Britain and Ireland on 28th ult., and published in your issue of 1st inst., my attention has been drawn by Mr. Greathead, M.I.C.E., to the statement that the "system of tunnelling is somewhat novel, and was introduced into this country by Mr. Greathead," is an error.

Under date of 12th inst., Mr. Greathead writes me as follows: "You are in error in supposing that the system of tunneling with a tubular shield was first suggested in America. Beach's American patent was taken out when the Tower Subway (begun in 1868) was more than half driven under the Thames, and long after the shield used in that work had been described and illustrated in English journals (facts which must have been well known to the editor of the *Scientific American*)."

Kindly insert this letter in your next issue, and oblige.—Yours, etc.,
G. A. Grindle.

7 and 8, Great Winchester-street, E.C., July 14.

P.S.—I may add that the statement in my paper above referred to was taken from the records of the Patent Office.

Electric Mining Locomotive.—A 10 h.p. electric locomotive has been used at the Hillside Coal and Iron Company, of Scranton, Pennsylvania, for three years past. The following is its performance for a sample day, Dec. 14, 1891: Distance of round trip, 5,284ft., average time, including stop to take out sprags, 10 minutes, number of cars per trip, 19, trips per day, 30; miles run per day, 30; total running time, five hours; delay, off rail 1¼, and other time 3¾ hours, total hauled, 784 tons. Engine replaces seven mules and six drivers.

THE ALTERNATE-CURRENT DYNAMOS.

BY R. W. WEEKES, WHIT.SCH.

Although the first dynamo-electric machines manufactured gave alternating current, the alternators exhibited 10 years ago at the Crystal Palace were destined to be quickly superseded by direct-current dynamos, which were then being rapidly perfected. A few alternators separately excited by Gramme dynamos were at that time put down in some private installation and used in conjunction with the first Swan lamps. This system soon fell into disuse, as it entailed extra expense and more machinery to keep in repair than the direct-current system. The discovery of the practical advantages of the transformer about seven years ago led to the rapid development of the new alternate current system of distribution, and consequently the design of an efficient alternator is of great interest. The tendency is to build machines for large outputs for central stations, but a few smaller machines are required for the periods of light loads. Several of the makers only exhibited their smaller alternators, but they illustrate the principles of the design as well as the larger sizes.

The alternators made at present can be split up into two characteristic divisions: First, those in which the magnetic lines have a fixed path of constant resistance, and the E.M.F. is produced by conductors intersecting this path; second, those in which the resistance and shapes of the magnetic circuit is varied, and the E.M.F. is produced by the change of induction caused by this.

The first class includes all the older designs, and may again be subdivided into two divisions—*i.e.*, those alternators which have moving armatures and fixed magnets, such as the Siemens, the Ferranti, and the Kapp; and those in which the field magnets revolve, as is the case in the Elwell-Parker, the Mordey, and the Fricker. In all these machines collecting rings are needed either for the armature or the exciting circuit, but as no commutation is required the collectors can be easily designed to run cool and sparkless.

In the second class of alternators the collectors can be dispensed with, and the manufacturers of these machines make this fact one of their claims for support. The Kingdon inductor, exhibited by Messrs. Woodhouse and Rawson, was the only machine of this class at the Palace.

Another way in which alternators have been classified is as to whether they have iron in their armatures or not. The next conclusion being that those which have no iron in the armatures had no self-induction. This error has been dispelled by the aid of the Ayrton and Perry secohm meter, as it was found that the self-induction of the Mordey armature was of the same order as that of those having iron actually in the armature. The disadvantage of the use of iron is that the change of induction in it is frequent, and consequently the loss from hysteresis may become large. This is a valid objection, but owing to the low induction used in the armature iron and to the small amount required, this loss can be reduced to about 1 per cent. of the output by careful design.

The following are the principal requirements which have to be considered in a good alternating-current dynamo to be worked at a high pressure: (*a*) Perfect mechanical design to ensure that the machine can be run continuously; (*b*) strength and stability in the armature; (*c*) perfect insulation in the armature coils, and arrangements so that little difference of potential shall exist between two adjacent parts; (*d*) ease of repair of a defective coil when needed; (*e*) the collecting gear should give no trouble; (*f*) efficiency.

I propose to describe the construction of the different machines in the order given above, and finally to give a tabulated list of them and their details as to output, weight, etc., for a means of comparison.

Messrs. Siemens Bros. and Co.—The alternator exhibited by this firm is of the low tension type, and is similar to the earlier machines made by them. There are in it many improvements over the original design. The magnets are constructed with wrought-iron cores, fitting into the cast-iron frame, which is cast in two halves and clamped together. The exciting coils are wound on brass bobbins, and so connected that the adjacent poles round the frame have always opposite polarity, and also that any two

It is in the armature design that this machine has been so much perfected. The cores round which the conductor is wound are made of laminations of brass and asbestos. The radial brass strips have a longitudinal corrugation pressed in them, so that when placed together these form keys to prevent any individual strip being displaced. The thickness of the asbestos between the laminations is increased along the radius so as to give the necessary angle to the core. When the core is built up to correct angle and thickness it is clamped firmly, and a brass connection is burnt on to the thin end. This is done by running molten metal over the ends of the strip till they fuse together. The core is then machined at both ends to the proper shape, and the solid brass end is drilled for the bolt, which acts as an electrical and mechanical connection. The inside end of the copper conductor is brazed on to this solid end. This copper strip also has a corrugation in it to prevent side displacement, and is wound bare with a strip of fibre as insulation between the succeeding turns. A large strain is put on the strip while being wound, and this forces the insulation well into the groove, which securely keys the turns together. In mounting the coils, one carrier is provided for each pair of coils, as shown in Fig. 2. There is a sheet of fibre insulation on each side of the coil when placed in the carrier, but the bolt which secures the coil *in situ* also connects the inner end of the conductor to the carrier. Hence the carrier connects the two inside ends of the coils it holds. The outside ends of the conductors are joined where the coils in adjacent carriers touch. This is done by brazing the two outside ends together before the coils are fixed into position. With this system of connection, it is clear that the individual carriers must be well insulated both from the frame and from each other. This is done by a process of casting in with a sulphur compound. The shank of the carrier is first insulated with porcelain where it passed into the hole in the driving ring. This ring is hollow inside, and a large rectangular nut is then keyed on to the shank so that it leaves a small space all round. A sulphur compound is then run into this place, and both firmly clamps the nut by expansion and also insulates it. The porcelain insulation is used to give a greater surface insulation, and also for fear a spark should ignite the sulphur if it was exposed. The two halves of the armature are connected in parallel so as to reduce the maximum voltage between any two coils.

In the present 245-kilowatt machine, when working at 2,400 volts, we get 200 volts produced in each bobbin, and hence a maximum difference of potential of 400 volts between the two adjacent bobbins in one carrier. At this place ebonite strips are introduced to tighten up the armature coils, and these strips thus give special insulation where it is needed. The lower ends of the coils are blocked up in the carrier by means of insulated metallic segments, shown in the sketch. This method of connecting the armature is exceedingly convenient in case of repairs being needed. If one coil should be injured by any mishap, it and the one next it in the adjacent carrier are unclamped and lifted out together, and the connection is completed to two new coils by the simple operation of bolting them into place. The connections from two diametrically opposite points on armature are taken through the inside of the main shaft to two well-insulated copper rings. The collectors used are two half rings of brass, with blacklead introduced to give the necessary lubrication and conductivity at the same time. The field magnets of this machine consist of wrought-iron slabs cast into the frame of the machine. The frame is built up in segments, and when bolted together they embrace the armature. The exciting coils are wound on formers and slipped on, being secured in places by the pole pieces. The oiling arrangements are exceeding well devised. The oil is forced up in the bearing at the underside of the shaft, and so tends to float it. The oil pumps at either end are worked by means of eccentrics fixed to the shaft.

The efficiency of the machine should be high, but although the lamination of the core will reduce the Foucault currents in the brass strip, it is probable that this loss will still be higher than the hysteresis loss in an iron-cored armature. The brass, however, gives exceptional stability to the armature. The power required to excite this machine is supplied by a current of 150 amperes at 30 volts, which is equal to 1·85 per cent. of the total output.

The following are the details of the alternator: Volts 2,400, amperes 100, speed 335; complete periods, 66 per second; number of bobbins, 24; conductor, 1 millimetre by [illegible] wide; number of turns per bobbin, 40; insulation, vulcanised fibre, ½ millimetre thick; weight of armature conductor, 250lb.; area of pole face, 126 square inches; exciting coils wound with 522 turns of 3·91 millimetre copper; weight of whole machine, 18 tons 7cwt.; floor space, 9ft. 9in. by 13ft. 8in.; height, 9ft. 3in.

LONDON CHAMBER OF COMMERCE.

[The following circular letter has been issued in connection with the Chicago Exhibition.—Ed. *E. E.*]

Dear Sir,—As you will no doubt observe from this week's issue of the trade papers, Mr. W. H. Preece, of the General Post Office, attended at the meeting of the Electrical Trade Section of this Chamber on Friday last, and gave reasons why the section should endeavour to co-operate in the organising of a representative British electrical exhibit at the forthcoming Chicago Exhibition. The Society of Arts, as you are aware, are acting as the British Royal Commission for this exhibition, and we are informed by Mr. Preece, as representing the electrical section of that body, that while other industries will send to the exhibition the most magnificent display ever sent by this country to any home or foreign exhibition, the electrical industry has up to now been an exception to the rule, and the articles to be exhibited are not considered to be anything like an adequate representation of the advancement which has been made in the application of electricity in this country during recent years, especially, too, as we believe the amount of capital invested in England has enabled developments to be made which have not as yet been equalled in any other country.

For your information I enclose a list showing the firms proposing to exhibit, the articles to be exhibited, and the space occupied.

Hitherto there has, we believe, been a disinclination to exhibit at Chicago, probably from a feeling of resentment, in the first place, to the McKinley tariff, and, secondly, because, apart altogether from this question, to exhibit there is not likely to result in developing any further trade with the United States. In regard to the first of these considerations, we would point out that if there were to be an entire absence of English exhibits, or even of electrical apparatus alone, visitors would seek for, and no doubt find, a reason for the absence of English exhibits in the McKinley tariff; but as certain firms find it an absolute necessity to exhibit, if they are to preserve the trade which they have already acquired with foreign countries, the question comes to be whether foreign visitors will not be entitled to regard the exhibits there as fairly representative of the state of the electrical industry in England. In regard to the second consideration, nearly all are agreed that the exhibition will not be productive of any trade with the United States; but in view of what has just been said, is it not desirable, in the interest of British foreign trade in general, that the industry should combine to make a representative exhibit? Such an exhibit would impress foreigners with the progress which has been made in this country in electrical science, and might possibly result in inducing them to make application later, if need be, to English firms instead of patronising nations who have created a better impression in consequence of a better display. Further, the various articles comprising the exhibit can be labelled prominently with the name of the makers, so that the exhibit will be personal as well as representative of the industry as a whole.

Mr. W. H. Preece suggests that this object might be accomplished by a certain number of firms combining as a syndicate to furnish a suite of rooms, and to have them decorated and lit up by electricity in the manner common to English houses. The expense would, of course, in this case be shared proportionately. If a response to this circular is received which would warrant our prosecuting the matter

further, then the Chamber would make an effort to secure the co-operation of the Furniture and Textile Trade Sections in supplying furniture, carpets, curtains, etc. In such an event the expense to each individual firm would, of course, be reduced proportionately. Mr. Preece has no doubt that the Royal Commission would be prepared to take charge of the exhibit, though possibly exhibitors would prefer to appoint someone to take charge of the exhibit who might be paid a commission on the sales. Free space has been provided, and only 5,000 out of the 20,000 square feet provided for electrical exhibits has as yet been allotted.

In order that we may know how far we are likely to be supported in endeavouring to carry out such a scheme as has been here indicated, I should be glad if you would fill up the enclosed form and return to me at your earliest convenience.—Yours faithfully,

KENRIC B. MURRAY, Secretary.

Questions.

1. Are you prepared to exhibit at Chicago on the lines indicated on the enclosed circular?

2. If so, what sum are you prepared to guarantee, it being understood that you would only be called on to subscribe proportionately, the proportion, of course, depending on the number of firms coming forward?

3. What would be the nature of your exhibit, and the amount of space you would be likely to require?

WHITEHAVEN.

Dr. J. Hopkinson, F.R.S., the consulting electrical engineer retained by the Whitehaven Board of Trustees Electric Lighting Committee to advise upon the question of electric lighting for the town, has sent in the following report:

On Friday, the 24th day of June, I visited Whitehaven, met your committee, and carefully examined the special conditions of Whitehaven in regard to electric lighting. The first point to be considered is the position of the generating station, for upon this will depend the choice of the system of lighting to be adopted. If the electric lighting station were established on the site of the present pumping station, which is close to the docks, a great deal would be saved in wages and a great deal also in coal, for it would only be necessary to keep up steam in one place to serve the two purposes of pumping and generating. I am therefore decidedly of opinion that the generating station should be placed upon the site of the pumping station. The demand for lighting in Whitehaven can never be very great, for I estimate that the whole of the gas accounts can never amount to more than about £8,000. The Trustees' order requires that they shall keep a supply during the whole 24 hours. If accumulators are not used, this will necessitate the presence of a staff of men at the generating station at all times. If, on the other hand, accumulators are used there will be many hours at all times of the year when the machinery might stand, and in summer it would be certainly unnecessary to run more than about six hours out of the 24. I therefore advise that in the case of Whitehaven, the three-wire system should be adopted, with accumulators for use during the hours when the demand is small. The price of gas in Whitehaven is 3s. 6d., and the quality I am told is inferior. Sixteen-candle gas at 3s. 6d. is equivalent to a supply of electricity at 5½d. per unit or thereabouts. I have no doubt that on anything like a reasonable scale electricity can be supplied at less than this cost, and, therefore, there is no reason to doubt that if the committee decide upon putting down a plant sufficient to supplant a considerable fraction of the gas supply and to charge a price not exceeding that which is now demanded for gas, they will obtain a considerable demand, and when sufficient time has elapsed for the light to be properly taken up will cover all their expenses, though they will not be likely to realise any very large profit. I have made an estimate of the cost of the plant which I would recommend, and upon this some explanation will be useful. It is proposed in Whitehaven to light up the bulk of the street lamps in the central part of the town by electricity. This can be done, and not unprofitably, for the hours during which these lights are used are considerable, and it is now an admitted axiom in electric lighting that a supply can be produced at much less cost when the hours during which it is used are considerable than when they are short. But the cost of arranging conductors underground for a comparatively limited number of lamps placed a considerable distance apart is considerable. This cost lies not so much in the main leads which convey the current as in the necessity for taking up a great length of streets for the purpose of laying one or two small wires to reach the separate lamps, so that these lamps can be turned off and on at the generating station without the necessity of a lamplighter going round to turn on and extinguish the lamps. The supply of electricity to the street lights is a perfectly definite problem, for one knows precisely the demand and one can arrange to meet it. It is not so with the general supply in the town to private customers, for these we must proceed on what I can only describe as a guess. In my estimate I have provided three pairs of feeding conductors, one pair capable of carrying 300 amperes, and therefore of supplying 1,000 16-c.p. lamps to the corner of Lowther-street and King-street, with distributing mains from that point; another pair for 500 lights to Corkickle, with distributing main; and a third pair for 500 lights to the neighbourhood of the hotel near to the station. The extent to which these conductors will be utilised will depend upon the extent to which the light is taken up. For example, in the last case the railway station would be a very considerable customer if they decided to take the light. For generating plant I recommend Willans engines, by which means the Corporation can get into the present available space at the pumping station sufficient power to supply the whole of the town, without any material structural alterations beyond what may be required for foundations for the machines. The size of engine selected is that which will give 60 i.h.p. when working at its maximum capacity. The rest of the items in the estimate explain themselves. The conductors provided are intended to supply 2,480 16-c.p. lamps, of which 408 are in the streets. Each engine in the generating plant will supply 500 lamps, and the battery will supply 330. The cost of adding additional power would be slight; it would be limited to additional engines and dynamos and additional feeding conductors. I have also made an estimate, given below, of the cost of working this station. This shows a total annual cost of £1,947. 10s. I have also made an estimate of the probable revenue to be derived from the sale of current and other sources of revenue. The first item in this account is a sum of £400 for the services of the pumps, the amount which, I am informed, is now expended in wages and coal. It further includes a sum of £800 for public lighting, for which will be given a very much better light than at present. The amount to be derived from the supply of electricity to private consumers is a much more uncertain item, as one can only guess at the number of consumers you will have and at the number of hours during which they will take their supply. A convenient method of charge is one which I recommended in Manchester, and which is intended to secure that consumers who use their light for many hours in the 24 shall be charged at a less rate per unit than those whose user is more brief. It is proposed that for each unit of power in the maximum power demanded by the consumer a charge not exceeding £3 per quarter be made, and in addition for each unit supplied a charge not exceeding 2d. For the present purpose, however, I assume that the average charge to the consumer is 5d. per unit, and that the average number of hours per annum during which the supply is demanded is 750, and that the conductors are used to three-quarters of their proper maximum current. On this basis the average revenue is £2,606, showing a profit of over £600. These figures satisfy me that if the committee adopt the bold policy of putting down adequate plant and adequate conductors, and charge a price something less than the present price of gas, they will be certain to secure such a demand for their supply as will render it remunerative.

5, Victoria-street, S.W., 6th July, 1892. J. HOPKINSON.

At a meeting of the Electric Lighting Committee, held last week, a letter from Dr. J. Hopkinson was read, in which he stated that he would superintend the erection of the works in accordance with his report for a commission of 5 per cent. on cost thereof. It was resolved that Dr. Hopkinson's report be adopted, and the committee recommended that the Trustees apply to the Local Government

Board for sanction to borrow £14,000 for purposes of electric lighting, and that Dr. Hopkinson be engaged to carry out the works on the terms named in his letter.

GRIMSBY ELECTRIC LIGHTING.

At a meeting of the Lighting Committee last week, the borough surveyor read the following report from Prof. W. Robinson upon the electric light installation:

In accordance with the instructions dated the 25th May, 1892, I have the pleasure to report that I attended at the Town Hall, Grimsby, on the 2nd June, and made careful tests and examination of the Crossley gas engine, Roper dynamo, and whole electric light installation.

Driving Gear.—I found the gas engine driving the dynamo, which gave a current of 150 amperes strength at 105 volts pressure, supplying all the glow lamps and one arc lamp. This load of lamps, taking about 21 h.p. effective output at the dynamo, required considerably more power from the gas engine, because of the excessive vibration of the belt and unsteady driving. The speed of the engine was found to vary between 188 and 192 revolutions per minute, causing the dynamo to run between 723 and 729 revolutions per minute, and a corresponding variation of two volts, in the electric pressure, from 104 to 106 volts was clearly indicated by the voltmeter. The diameter of the driving flywheel is very nearly 6ft., and that of the driven pulley 1ft. 6in., and the distance between the centres of their shafts is only 11ft. The short drive of 13ft. 6in. given in the original plans has been reduced to this still shorter drive of 11ft. by turning the engine round from the proposed position. Further, I found the bearings of the shaft carrying the driven pulley, heavy disc, and dynamo in an unsatisfactory condition. One bearing of the dynamo was heated, although well lubricated; also the journal and pedestal near the heavy disc were quite shaky, the brasses being kept loose to prevent overheating, and the pedestal and journal were not nearly large and massive enough for the power, speed, and driving conditions. The fast and loose pulley mentioned in the specification has been replaced by a pulley provided with flanges 3½in. deep, in order to keep on the driving belt, which was frayed on one edge, due to working against the flange, showing that the belt tends to slip off the pulley. The belt appeared to be made of "Scandinavia" cotton belting, pliable, strong, and well suited to the work, because it runs more smoothly and quietly than leather. I am of opinion that the tendency of the belt to be thrown off the pulley is due to three causes. First, the great difference in size of flywheel and driven pulley combined with the comparatively short distance between their centres; second, the sudden fluctuations in rim speed of flywheel of engine from one explosion in the cylinder to the next, especially when there is a miss between them; and third, the side slipping of the belt points to the shafts not being truly parallel. Anyhow, the driving is unsteady and unsuitable for electric lighting, and the shafting needs alteration.

Dynamo Machine.—After two hours' run with the above load, taking a current of 150 amperes, the rise in temperature of the coils of the dynamo was found to approach close to the limit of safety, which would certainly be exceeded were the current to become 250 amperes as marked on the brass plate on terminal board of the machine. In fact, dangerous overheating and consequent breakdown of the installation would be produced by a constant current much above 200 amperes maintained for several hours, and the dynamo is not capable of producing and maintaining an electrical output of 30,000 watts at 110 volts under ordinary working conditions as set forth in the specification. I do not advise you to put on the dynamo more than 300 lamps taking 180 amperes, which is about the maximum safe working load at 110 volts; that is, the maximum output is about 20,000 watts, or two-thirds the power specified.

Range of Ammeter.—I consider the ammeter, reading up to 400 amperes, is unsuitable for the present requirements of the installation. Since the greatest range of current marked on the dynamo is 250 amperes, an ammeter reading up to this limit would be more serviceable than the present one; moreover, the normal working current of 150 amperes at present taken from the machine could then be indicated more clearly on the scale of the instrument, and read with greater accuracy.

Voltmeter.—I tested the voltmeter by comparison with a standard Cardew voltmeter, and found it correct.

Gas Engine.—The gas engine was tested with a rope brake on the driving flywheel. The first trial was running light, next with the load gradually increased from 9 h.p. to 28 h.p., and finally with full load, the gas supply being adjusted to keep the speed at 192 revolutions per minute. The mean of the full load tests was at 33 actual horse power, and the maximum reached was 38 effective horse power on the brake at 192 revolutions per minute. The mean gas consumption observed was at the rate of 31 cubic feet per effective or brake horse power per hour throughout the trials. The engine behaved well, fully coming up to the terms of the specification, and capable of giving out greater power than required by the dynamo.

Electrical Tests: Insulation Resistance.—The electrical resistance between the two leads, as well as the resistance between each lead and the earth or ground, was tested by means of a Wheatstone bridge, with the following results: Resistance between two leads, about 2,000 ohms only; resistance between positive lead and earth, also about 2,000 ohms; resistance between negative lead and earth, about 90 ohms. The above values of the insulation resistance were obtained with a battery of only two Hellesen dry cells. The dynamo was next run at its normal speed, giving 105 volts of pressure at the terminals, and a current of about 150 amperes. One terminal of a Cardew voltmeter was connected to a gas bracket, and the other to a wire which was connected to both terminals of the dynamo in succession. When joined to one of the terminals, the voltmeter gave a reading of 105 volts, showing and proving that one of the mains must have been "earthed." The same experiment was repeated, but using a water-pipe for "earth" instead of the gas pipe, with the same result as before. The above tests prove conclusively that the insulation of the installation is in a very unsatisfactory condition, and requires immediate attention. The main lead to the double switch on switchboard in the engine room was also found to be "earthed" somewhere. This is against the Board of Trade regulations, and attended with danger to public safety.

Arc Lamps.—On examination of the arc lamps the resistance coils used in series with these lamps were found to be in a bad condition, and were in contact with the iron frame supporting them, which was fixed to the outside wall and exposed to the weather, pointing to the probability of the leakage to earth occurring there. This arrangement of the resistance coils outside the building, exposed to rain, snow, frost, etc., is calculated to give serious trouble, especially in winter, when the light is most wanted, since the coils might readily be short-circuited and the current leak to earth, and thus interfere with the proper work of the whole installation. It would, therefore, be highly advisable to place the coils in special boxes, so as to ensure good and high insulation, else the arc lamps cannot be relied upon to burn properly.

General Fittings.—The electroliers are excellent. Although the specification states (page 6) that the "wiring and installation throughout is to be carried out in accordance with the rules of the Phœnix Fire Office," these rules are ignored in the specification itself, where the existing gasoliers are proposed to be used, evidently to keep down expenses, and yet rule 23 is to the effect that "gas fittings should never be utilised for the electric light, and they "must not be used without special sanction." Furthermore, I advise that at least ceiling roses for insulation should also be placed wherever conductors are led down from the ceiling to the existing gasoliers, instead of the bare holes in the plaster with the conductors passing through. In order to be safe against fire risks it is highly desirable to have the installation approved of by the inspector of your fire insurance company, because my experience of the Phœnix Office is that your installation is not fit to be passed. Even the highest value of the installation obtained by the above tests is far below what the insulation resistance of the whole installation should be, and the tests prove conclusively that the mains are practically joined to earth when the ordinary working electric pressure is applied, and therefore require immediate attention and repairs. The inevitable conclusion to be drawn from the above facts and figures, as the results of my tests, is that the installation in its present state is not a first-class job, and the electrical part especially is incomplete, not being in proper working order, and has not been carried out in accordance with the terms of the specification. I should strongly advise you to use accumulators as reservoirs and regulators: first, to keep some lights, as at the police department, going all night, and as a reserve in the event of a breakdown of machinery, bursting of ignition tube, etc.; and second, to steady the light and prevent blinking or winking caused by the irregular explosions in the gas engine cylinder and throb of the driving belt. (Signed) WILLIAM ROBINSON,

Professor of Mechanical and Electrical Engineering.

The **Chairman** remarked that so far as the actual working of the light was concerned, they had quite sufficient evidence upon that point. They knew that the light jumped and at certain periods was not satisfactory, and it seemed to him that an explanation of the defect was to seen at once in the opening of the inspector's report. They must be right with the engine, however much they might be at fault in other departments. If they were not right in the first instance—in the motive power—they could not be right anywhere. The inspector had pointed out what had been in his (the chairman's) mind for a long time—that the unsteady driving they had at present was more expensive than smooth running. He was perfectly willing to subscribe to everything stated in the report upon this point.

The **Borough Surveyor** pointed out, on the subject of the dynamo, that the cheapest course would be to put in a new one altogether.

The **Chairman**: If the contractors have supplied a dynamo two-thirds the strength required, they must take it up and put down one of the full strength.

Mr. Connell said that would not be an expensive matter. It would simply be a case of substituting another dynamo, and taking back again the one at present in use.

The **Chairman**, after some further discussion on matters of detail, remarked that their business was to pass a resolution calling upon the contractors to carry the work according to the specification and to finish it properly. If they would not finish it, it remained for the Corporation itself to conclude the work and debit it against the contractors. Therefore he moved that the town clerk write calling the attention of the contractors to the fact that the specifications had been seriously departed from, and stating that it was required they should at once do what remained to be carried out.

Mr. W. Mudd seconded the proposal, which was agreed to.

It was decided that the borough surveyor should report as to what was the value of the alterations and electrical fittings at the Town Hall, in order that the insurance might be arranged for.

ACCUMULATORS NEEDED.

The **Chairman**, referring to the last clause in the report, said he had always been of opinion that their installation would never be complete unless they had accumulators especially if they intended to light the police department with electricity. He believed it would be economic if the Corporation arranged to procure accumulators that would run the light for three hours. They would be particularly useful with respect to committee meetings and the requirements of the surveyor's office even the Council chamber as well. None could deny that the electric light was an improvement upon the old system, and when they had everything completed he had not the slightest doubt that it would be more economic and satisfactory.

The **Borough Surveyor** stated that from enquiries he had made he thought £300 would leave sufficient margin for getting all that was required.

The **Chairman** said it had been thought they could get a very fair set of storage apparatus for about £100.

The **Town Clerk** reminded the committee that it was a question also of renewal.

The **Surveyor** stated that the company with which he had been in communication were agreeable to attend to the accumulators for a time not less than five years at a charge of 10 to 12½ per cent. per annum on the total cost. That would be about £35 per year.

The **Chairman** said that question required careful consideration. It might very well stand over until the next meeting.

The **Surveyor** had found that in nearly every case where the electric light had been adopted accumulators were in use.

The **Chairman** said there was absolutely very little cost in the manufacture of the accumulators; the high price was on account of the tax put upon them by way of patent.

The surveyor was instructed to procure further information upon the subject.

LEGAL INTELLIGENCE.

THE MEDICAL BATTERY COMPANY v. JEFFERY.

Harness's Electropathic Belt.

Mr. C. B. Harness, of electropathic belt fame, has at last met an opponent with the courage of his opinions upon a disagreeable experience, and has been badly thrown in the encounter. The case came before Judge Bacon at the Bloomsbury County Court on Tuesday, the suit being The Medical Battery Company v. Jeffery. The claim was for £3. 5s., balance of account for a five-guinea belt (the same kind, by the way, that Dr. Silvanus Thompson declared had no value "except in the flannel"). A counterclaim was put in by Mr Jeffery for his I O U. for £3. 5s. and the return of £2 paid, on the ground of misrepresentation, and that no good consideration was given for the money.

The defendant, a bank clerk, came to the Electropathic Institute thinking he was suffering from a sprain, and would require a truss. He asked for a qualified man, and was introduced to Mr. Simmonds, who advised him to wear a belt price £5. 5s., and so prevent rupture. The sum of £2 was paid, and an I O U given for the remainder. Later, Mr. Jeffery complained of the belt, as it caused sores and aggravated the complaint. He had consulted a medical man, who ordered him to leave it off as in no way suitable for rupture. He was met with request for payment. He then instructed Messrs. Lewis and Lewis to proceed for return of the money, but found that proceedings had already been taken by the company. The counterclaim was then entered.

Mr. Frederick Thomas Simmonds, examined, stated that he had had great experience in fitting trusses, having attended over 16,000 cases. He was therefore a qualified man, though not a "qualified medical man." The defendant was not absolutely ruptured—only internally. He (the witness) recommended an electric belt to give "tone" to the system. He had been employed in the company for seven years, and began treating hernia after he had been there three months. Before that he was salesman in an Oriental furniture warehouse, but had studied hernia since he was nine years old. There was protrusion of the bowel through the internal ring in this case; he did not know what effect the electricity would have. The belt, weighing 2lb. or 3lb., was, he considered, the proper one for internal hernia. They had 500 in stock. The patient would not require more electricity than he could get out of the belt. "Is there any electricity here?" "Yes." "Do you pledge your oath that there is an electrical current?" "I have no knowledge of electricity. I have sufficient knowledge to know it would be useful." "Would the patient get a serviceable amount of electricity?" "Yes, certainly, as the moisture of the body would complete the circuit." "What is the cost price of the belt—15s.?" "I have nothing to do with the cost of the goods. I am a little above that sort of thing. Mr Harness had a large number of patients. I am not an electrical expert. I do not know how the current passes."

Mr. Lickfold, addressing the Court, said the defendant was a cashier in the Union Bank, and having, as he feared, ruptured himself, his attention was attracted to an advertisement of the Electropathic and Zander Institute, 52, Oxford street, where medical advice was given gratis. He asked to see a medical man. He saw Mr. Simmonds and told he was suffering from rupture. Mr. Simmonds examined him, and told him he was not so suffering, and added: "You must have one of our belts and that will set you right." The defendant was fitted, and took a belt costing £5 5s. Instead of doing good, the belt chafed the skin and caused an eruption, and the illness was so aggravated that the defendant consulted a medical man, Dr. Rowntree. After going through the facts, Mr Lickfold said he should produce evidence to prove that these so-called electric belts were nothing else than fraudulent impositions. People were inveigled into this trap, and belts, which were absolutely worthless, were palmed on them, and they were ashamed to proclaim their folly by prosecuting the promoters of these impostures. But it was now time that it should be put a stop to. The learned gentleman submitted that there had been misrepresentation in this case, because Mr. Simmonds was not a qualified man, and because he misled the defendant by telling him that he was not suffering from hernia when he was so suffering. Then the defendant was entitled to have his money and I O.U. returned to him, as he had not received any good and proper consideration for his money.

Mr Jeffery was then examined, stating his experience, how a lump in the groin formed afterwards a sore, and that he had then consulted Dr. Rowntree.

Mr William George Rowntree, L.R.C.P., said Mr Jeffery had been suffering from rupture for a month, or even three, when he called. The belt was not of the slightest use. He recommended a truss, and the patient is getting better.

Mr. T. E. Gatehouse was then examined. He stated he was an electrical and consulting engineer of 22 years' practice. He had examined and tested the belt. It was absolutely worthless. As arranged, the belt could produce no electricity at all. The moisture of the body would set up a current between two dissimilar metals, but there must be a complete circuit. There is no completion of the circuit under the belt.

His Honour: Why, would not a body touched back and front and all around complete a circuit?

Witness. As this belt was worn it never produced a trace of electricity. This morning I made an experiment with this belt, so as to produce a small quantity of electricity. I took salt water and moistened the two parts, and then I connected the copper and zinc with a galvanometer, and so I got a slight deflection of the needle of about 14deg. I then put the belt on my legs and on my arms, and the deflection was not in the slightest degree altered. That shows that when these belts are worn by any patient no electricity passes through the body in any way whatever, but only along the webbing of the belt and over the skin surface. Electrically these things are useless.

Mr. Lickfold. Then you say this belt electrically is absolutely a useless article?

Witness. Yes.

Cross-examined by **Mr. de Witt**: Zinc and copper are used in generating electricity.

Do you say that this belt would produce no current at all?

Witness. Not as the defendant wore it. The circuit was not complete! I saturated this belt with salt water and then I got a small electrical current. I say there is a current if properly connected up, but the current will not go through the body—it is the webbing and skin, and not the body, which forms the internal circuit.

This concluded the evidence.

His Honour, in giving judgment, said: I think it is clear, on the evidence, that the defendant went to the plaintiff's establishment and asked to see a qualified doctor. That was uncontradicted. The defendant was shown that the gentleman whom he saw (**the gentleman who calls himself an "expert"; a gentleman** without any medical education, or education in this matter, except having studied the best works on the subject since he was nine years of age), and when he asked for a truss, recommended him something which he said was better. The defendant has shown that this gentleman told him he was not suffering from rupture, **but only from the beginning of rupture. I have no doubt from** the evidence Mr. Simmonds said to the defendant: "**I am happy to tell you you are not ruptured." But that was not the fact; the defendant was ruptured, as I cannot help believing** from the evidence of Dr Rowntree. He went for a truss. He was told, "You do not want a truss." This is a representation made by a man who had not taken the trouble to qualify himself, and who ought not to have made any representation at all. This was the representation which led to the contract, a contract without any good of any sort to the defendant, **and it must be voided. There must be judgment for the** defendant on his counterclaim, and his £2 must be returned to him.

Mr Lickfold applied for costs on the higher scale.

His Honour refused the application. Judgment accordingly.

COMPANIES' MEETINGS.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors: James Staats Forbes, Esq., chairman; Major Samuel Flood Page, deputy chairman; the Earl of Lichfield; Shelford Bidwell, Esq., F.R.S., Ernest Villiers, Esq.

Ninth annual report of the Directors presented to the shareholders at the meeting of the Company, held at the Cannon street Hotel on Tuesday, July 19.

The business of the Company has resulted in a credit balance of £74,810 16s. 7d. Of this amount £30,271 15s. 11d. has been already distributed as an interim payment on the A shares for the first six months of the year in respect to dividend and arrears. The Directors recommend a further distribution of a dividend on

the A shares of the Company, of 5s. 8¼d. per share on the 80,261 ordinary shares, £3 paid; of 9s 6¼d. per share on the 5,000 £5 fully paid shares allotted to the Edison Electric Light Company, Limited; and of 8s 10¼d per share on the 12,139 £5 fully paid shares allotted to the Swan United Electric Light Company, Limited, free of income tax, being, with the interim dividend paid on the 22nd February, 1892, 7 per cent. in respect of the year ending 30th June, 1892; 7 per cent., in payment of arrears of cumulative preferential dividend for the year ending 30th June, 1887; and of 4 per cent in respect of the year ending 30th June, 1888; all to be distributed in accordance with the provisions of clause 87 of the articles of association which will absorb £33,354 4s 9d., leaving £11,184 15s. 11d., which the Directors have carried to the reserve fund, in accordance with clause 89 of the articles of association. The Directors are glad to say that their electrical fittings business is prospering. The amount received as royalty from those who hold licenses for manufacturing holders and sockets for incandescent lamps is satisfactory, and is likely to increase year by year. The Directors desire to record their sense of the loss which the Company have sustained by the death of Mr F. R. Leyland. The Directors have elected Major Samuel Flood Page, who had been secretary and manager of the Company since 1883, to fill the place on the Board. The Earl of Lichfield and Mr Ernest Villiers retire by rotation from the Board, and offer themselves for re-election as directors. Messrs. Welton, Jones, and Co., auditors, also retire, and offer themselves for re-election.

PROFIT AND LOSS ACCOUNT, YEAR ENDED JUNE 30, 1892.

The annual meeting of the Edison and Swan United Electric Light Company Limited, was held on Tuesday at the Cannon-street Hotel, Mr James Staats Forbes (the Chairman of the Company presiding.

The **Secretary** (Mr. H. Charles Cover) read the notice convening the meeting. The report and accounts were taken as read. (These we give in this issue, as we received them too late for insertion in our last.)

The **Chairman** said: Gentlemen, I have had occasion before to call attention to the position of a company like this, where circumstances operating upon its interests make it expedient that the accounts should be stated in a manner rather more general than in some other companies which have a statutory form of accounts. I suppose as the day arrives when our patents are running out that reticence becomes even more necessary than in the earlier stages and that is why these accounts are so brief in statement, and are confined to so few elements as compared with the accounts of [illegible] other public companies. The essence of all these accounts is what profit has been made, and how we propose to divide it. I [illegible] remind you of the peculiar position of this Company, and why, however satisfactory the result, as shown upon a particular year, may be in the distribution of dividend, it is necessary to bear in mind that there are some considerations acting rather in depreciation of the dividend. For instance, we shall propose to you to divide [illegible] the profit realised on the year as, with the provisional dividend paid on six months, amounts to 18 per cent. Last year we paid 17 per cent. the year before that 15 per cent., and in 1889 the first dividend paying year at all, we paid 10 per cent. Well, there is nothing so readily excited as the cupidity of mankind, and as our business is being watched with a great deal of interest by many outsiders who, when it becomes an open business, will be ready to launch upon it in competition with us, it is just as well to bear in mind that for the five years preceding those I have alluded to we paid no dividend at all, and perhaps it may [illegible] not our satisfaction, but the aspirations of some other people to know that, notwithstanding that we propose to pay this dividend to-day, really over the nine years the aggregate amount divided has only reached the moderate sum of 6¼ per cent. Now, as to the accounts themselves. I think I had better first take you through the working account. You will see it is very simple; it consists of only three or four headings. We begin every year, of course, with a large stock of lamps and material in anticipation of our requirements and manufacture on account of the current year, and the accounts of that carried forward from year to year are a matter of some importance in forming an opinion as to the position of the Company. It may be too large, or it may be too small. If it is too small the Company may be placed at a disadvantage in the event of a sudden growth in the demand, or if it is too large it will involve the locking up of more than a necessary amount of capital invested in the stock. Well, you see that on July 1, 1891, we brought into the accounts £59,308 worth of stock. That was made up largely of lamps, and of platinum and other material in hand. During the year, to keep abreast of the consumption and ensure the possession of a large stock, we have spent in wages, purchases of materials, etc., £59,000; that is the bare cost of the lamps produced at the factory—the mere mechanical part of producing and material worked up in the production of so many lamps. Then came the whole of the administration expenses, various heads of departments, directors, and all that machinery which represents in a public company what the brains and directing influence of a partner or partners, represent in an ordinary firm. Then there is a [illegible] amount, but quite sufficient, put down for depreciation of plant. On the other side of the account there are by sale of lamps, fittings, royalty on holders, etc., £166,348; interest, etc., [illegible] and the stock on hand when we emerged from the year, [illegible]. Of course, the difference between these two is the balance of profit to be dealt with for the year, which amounts to the respectable sum of £74,810. Now, what I want to call your attention to is that this account is satisfactory in the sense of our having considerably diminished the amount of money locked up in stock; and I think I may say that [illegible] without at all fearing questions upon the other possibility that there is not stock enough on hand to meet any sudden emergency. I think we may say to that extent our position is a little more wholesome than it was 12 months ago. The large figure of £166,348 is not made up exclusively of the sale of lamps, because

for the last two or three years we have ourselves been manufacturing fittings which are the adjuncts to lamps. We were driven into the necessity of making the fittings, first of all, because the holder of the lamp was a very delicate instrument and we found we could do it better than anybody else; so we acquired some very interesting and ingenious patents for fittings, and we are manufacturers, and also licensors. People who were gasfitters have become electric light fitters, and we give them the opportunity of manufacturing their own fittings if they choose, and they do that on the basis of royalty. From royalties paid by these licensees we receive a considerable annual sum, the advantage of that being that, whereas the lamp patents will expire at no very remote date, the patents for these fittings will run over a good many years, and afford us, for what I may call the protected period, a very considerable and growing annual profit. Respecting the balance, we have already distributed in the course of the year a considerable portion of it in the nature of a dividend, and we propose to apportion the remainder so as to produce this 18 per cent. upon the year; and, in order that you may understand that, I would refer you to paragraph 2 of the report, which is somewhat long and complicated. You will see it only repeats what I have told you—that the dividend of a particular year being limited to 7 per cent., all the rest of the profit goes in aid of those years during which no dividend was paid, because the 7 per cent., according to the contract between the partners, was to be cumulative. In addition to the capital upon which this is divided, we have, as you know, £117,000 of deferred shares, representing the proportion which Mr. Edison and his friends hold of the capital of this business—the consideration, in fact, for his patents, and so forth. Well, he has never received anything at present, nor can he or they who hold the shares receive anything until the A shareholders have received 7 per cent., not only in respect of the current year, but in respect of all past years. You will see in the paragraph to which I am referring that we have wiped out everything up to June 30, 1888. We still have on that account a considerable sum to meet out of future profits before the deferred shares get anything. Now, by the statement in the balance sheet showing the proposed appropriation of profits, you will see that the profit brought down from the working account is £74,810. 16s. 7d. The dividend for the year ended June 30, 1892, at 7 per cent. per annum, comes to £24,743. 9s. 2d., the payment of cumulative preferential dividend on the A shares for the year ended June 30, 1887—one of the years for which we paid nothing—at the rate of 7 per cent., to £24,743. 9s. 2d., and the payment on account of cumulative preferential dividend on the A shares for the year ended June 30, 1888, at the rate of 4 per cent., to £14,139. 2s. 4d. That comes altogether to £63,626. 0s. 8d., and that is the amount which we propose to distribute out of the £74,810; the balance we propose to carry to the revenue fund. That, of course, requires your confirmation, and we shall submit at the right moment a resolution authorising that application of the balance, which we hope you will approve. I think I had better come to the general paragraphs of the report, which, as a matter of fact, I think I have already exhausted. The third and fourth paragraphs say: "The Directors are glad to say that their electrical fittings business is prospering. The amount received as royalty from those who hold licenses for manufacturing holders and sockets for incandescent lamps is satisfactory, and is likely to increase year by year." I have gone through the same story in rather more words in what I have told you about why we entered upon manufacturing, and that this is a growing asset, and one having the great advantage of being protected by patents for a good number of years. Now I come to paragraph 5, which in very brief words records what in the earlier days of the Company would have been a positive calamity to us, and, even in these days, when we have felt our footing, and got this business upon something like a sound basis, is still a very serious loss, and that is the death of our old friend Mr. Leyland, which was almost awful in its suddenness. This loss created a vacancy, and we thought that, looking at the position which Major Flood Page had held in the Company for a good many years, and that he, like some of the rest of us, was not getting younger as time went on, he might very properly be relieved of some of the harrassing details of the business which it had been his lot to attend to as secretary, and put upon the Board in place of Mr. Leyland. Accordingly, we elected him as deputy chairman, and I hope you will confirm the judgment of the step we have taken. As to the balance sheet, the figures, in so far as the capital is concerned, are exactly where they were in the previous accounts—we have not increased the capital. Then there are sundry credit balances which show that we owe £16,493, and against that item may be set debtors on the other side, which amount to £30,800, and, as these are all good, you can see that we are all right there. Next we come to the balance brought from the profit and loss account, £74,810. 16s. 7d., from which is deducted interim dividend at the rate of 5s. 3d. per share on the A shares, £3 paid, 8s. 9d. per share on the fully-paid shares allotted to the Edison Electric Light Company, Limited, and 7s. 8d. per share on the fully paid shares allotted to the Swan United Electric Light Company, Limited, paid on February 22, 1892, amounting together to £30,271. 15s. 11d., and leaving a balance of £44,539. 0s. 8d. On the other side of the account is the old item brought forward year after year, showing where the money has gone to. This £234,638 represents the costs of patents, goodwill, preliminary outlay, loss on working, etc., as against £375,000 of A capital. Then come the assets. Firstly, £12,000 in the Manchester Edison-Swan Company, Limited, which pays no dividend at present. I do not know whether it is within the bounds of possibility that that company will pay a dividend on their deferred shares. If they do, that asset will be worth something; if not, it will not be worth much. Then come freehold property, £39,435, and plant and stock £67,328. With respect to the freehold property, we bought a considerable acreage of land at Ponder's End, with enormous buildings thereon, for the purpose of a factory. That land and the buildings were sold to us at a moment of great depression, and under circumstances which made the bargain for us exceedingly advantageous. The plant and stock represent the two items I have spoken of, lamps and so forth in hand, and the plant and machinery which we out of capital bought to make that factory a going concern. I suppose I may say that if we had to start afresh and find land in a position as advantageous, and put upon it buildings and plant as efficient as we have got now, it would cost a great deal more than these two sums represent, from which I draw the inference that as long as this business can be pursued we have a factory and land bought very economically, with a capacity for production which is very large, for a good number of years as a going concern, which will be of great value to this Company, and may be regarded as a very sound asset. Office furniture is put at the moderate figure of £173. 7s. 8d. We have written down from year to year nearly the capital value of the few luxuries we possess in the office. Debtors I have told you about; our investment in consols at cost stands at £20,000, and the cash at bankers and in hand is £30,719. That is the state of our accounts, which are very simple; and now, subject to answering any questions, I will move "That the report and accounts for the year ended June 30th, 1892, be received and adopted."

Major Flood Page seconded the motion.

Mr. Lorraine said the whole history of inventions showed that a patentee made more profit after his patent rights expired than while they lasted. The reason was that, although a hundred competitors might come forward, a hundred men thus advertised his goods, and he had established his market for their sale. The fear in regard to this Company seemed to be that as soon as their patents expired their profits were going to disappear; but he was strongly of opinion that that was not going to be the case. Electric engineers told him that, for some years at any rate, they will be afraid to specify any lamp but the Edison and Swan, because that was the one they actually knew. Another argument was that they were going to have lamps introduced from other countries, where labour was very cheap; but he believed that even in that event they would avoid a loss, inasmuch as their relations with the Swan Electric Company were such as to make it merely gaining money from one pocket which they lost from another. Mr. Lorraine also referred to the Company's getting part of their goods manufactured in Germany.

In reply, the **Chairman** expressed a belief that after the expiration of their patent rights in the lamp, there would be such an expansion of the business that the profit derivable from the lamp would remain in the hands of those who had the best trade-mark and the best hold upon the business—advantages which their Company had been aiming at securing. If they found hereafter that lamps could be produced at 2d. or 3d. each cheaper than in London, owing to the cost of labour, they were in a position to get them at their own factory in Germany, for the Swan United Company would be delighted to take an order from this Company to deliver lamps in London. If the London Trades Council became much more powerful the rate of wages, instead of being fixed by the master, would be decided by somebody else. Although in Germany there was a great deal of talk about Socialism, it was not so much practised there as in this country, and if the Company had much difficulty with their workmen in the future, they might be able to get their lamps made more cheaply in Germany. That showed the propriety of putting their two coaches—the English and the German—together.

The motion was then unanimously agreed to, and the resolution declaring the dividends was also carried.

The retiring Directors and auditors were re-elected, and the proceedings closed with a vote of thanks to the Chairman.

NATIONAL TELEPHONE COMPANY.

The annual general meeting of the National Telephone Company, Limited, was held on the 14th inst. at Cannon-street Hotel, E.C., Mr. James Staat Forbes (the chairman) presiding.

The **Secretary** (Mr. Albert Anns) read the notice convening the meeting.

The **Chairman** commenced his observations by sympathetically alluding to the loss the Company had sustained by the almost tragic death of their late president, Mr. Leyland. Literally (the Chairman said) Mr. Leyland died in harness, and almost his last words and thoughts were of the affairs of the Company. He went straight from the office, where he laboured ungrudgingly, and in 10 minutes he was gone. Some of them had the melancholy duty to perform of attending his funeral, and they came away bringing with them the impression, which could never be effaced, of the ability, experience, and devotion he had displayed during very troublesome times, and under very great responsibilities. Referring to the report, he proceeded to say that it was not so bad as it looked. The essence of it was in the first three paragraphs, which showed what they had earned, what it cost to earn it, what there was left, and what they proposed to do with it. The income accrued in respect of the business of the year amounted to £463,741, which was £32,000 more than in the corresponding half-year. Their business was a peculiar and, in some sense, an interesting one. Their subscribers paid in advance, and they also paid for intervals of time not limited by a particular year. A man might become a subscriber on January 1, but the financial year ended on April 30, and, therefore, although they took the subscriptions in advance

for 12 months, obviously only a portion of that subscription could be attributed to the business year. Consequently, there was an income of an accumulative kind, and there was an income for which the service had been given in return, which made the actual income of the year. In the first column of the abstract of accounts at the foot of the report, they gave the accrued income of the business of the year. The rentals or subscriptions which had been received in advance amounted in the aggregate to £234,000, which had been carried forward to the next year. The shareholders would be able to gather from the abstract of accounts what progress had been made from year to year, the net result, and the dividends. They would see that, concurrently with the increase in the income of the year, they had had a considerable increase in expenditure, and that the net revenue had become chargeable in respect of that increase with the considerable sum of £38,000. The increase of £32,628 upon so large a figure as £431,000 did not seem too brilliant. It was, in fact, only 7 per cent. of the whole; but there were one or two things which had to be considered. They had referred in paragraph 3 of the report to the fact that, in anticipation of certain things, such as the expiration of the patents, they deemed the time had arrived to relieve the subscribers of some portion of the rentals. The year under review was the first complete year in which those reductions came into operation. If the same number of subscribers that existed at the beginning of the year had paid the old rate during the whole of the last year, they would have added £55,000 more to the income. Of course, that was only in respect of the number of subscribers who were on their books at the beginning of the year ended April 30 last. In the interim, of course, they had obtained a considerable number of new subscribers, but he was not estimating anything in respect of the new subscribers, who all came on at the new rate. But a cession of £55,000 to their subscribers was, of course, a serious matter. They might have retained the old subscribers at the old rate; but probably they would not have extended their business, and might not have made that advance in the public confidence which they had done. However, they were pretty sure to have retained a larger income, although it was a wise thing to accede to the reduction. It must be borne in mind, in judging the progress of the year from that point of view, that that large sum of money had been returned, so to speak, to the pockets of the subscribers; and as a good many of them were under contracts for succeeding years, it was a very substantial gift for them. Well, there were some other things to be considered, in virtue of their patents. Up to the time of their expiration they were entitled to receive from subsidiary companies a royalty. On the item of royalty there had been a loss of £5,000. Besides that, they sold a number of instruments, and when they were patented instruments they got a bigger price; but now they were open they got less. By that they had made a loss of £1,000. There was another item which also showed a loss, and that was the balance brought forward. In the preceding year it was £11,000; but in the year that they were dealing with it was only £5,000, and therefore there was a diminution of £6,000. On that score, therefore, no less a sum than £65,500 was to be accounted for in the three ways he had referred to. They had some advantages. They were shareholders in one or more subsidiary companies, and the dividends from them in the year under review exceeded by £1,100 the dividends from the same source in the preceding year, and they were also fortunate enough to have more cash at their bankers' from time to time, and their interest account benefitted by about £1,000. He estimated that if they had not reduced the rentals, £65,000 would have been added to the increase of income. With regard to the working expenses, they had increased by £36,768; therefore the expenses had increased and the receipts diminished. Why had those expenses increased in that ratio? First of all, their income, notwithstanding the drawbacks he had mentioned, increased £32,628, then the number of new subscribers had increased. When they compared the increase in the number of subscribers with the increase of expenses they would find that the increase in the former was 20 per cent. and the increase in the latter 18 per cent.; therefore the expenses had only kept pace with the increase in the number of subscribers, and scarcely that. There was another thing which told against them: they paid royalties upon the gross income, and not the net, and, therefore, all the reductions which were called for by the public came out of that profit. They had, therefore, a less net income than they had last year. Out of the divisible balance, after providing for interest on debenture stock, an interim dividend of 6 per cent. per annum for the first half year had already been paid on the first and second preference shares, and 5 per cent. per annum on the ordinary shares. The Board would recommend the payment of a further dividend for the last half year at the rate of 6 per cent. per annum on the first and second preferences and 7 per cent. on the ordinary shares, making 6 per cent. for the year. The dividends, therefore, remained the same, but the balance carried forward had diminished. The Board proposed to transfer to the reserve account £10,000, which, with £1,127 placed to reserve during the year from premium account, would bring up the amount of the reserve to £104,627. There were two methods of getting a profit, one was looking forward and the other sticking fast, which encouraged dissatisfaction and competition about charges, which the public believed were immoderate. They had emerged from protection and were in the more healthy atmosphere of free trade, and they had to take care not only that their service was made as effective as skill and money could make it, but that the charge for the service was so moderate in relation to its value that customers should not be tempted by competitors who were always ready to bid for business at ruinous rates. What they had done was to prevent the possibility of competition, and the result appeared to them to be not only highly satisfactory as regarded the particular year, but very encouraging as regarded the future, because 20 per cent. increase in the number of subscribers was not an inconsiderable increase. That really was the essence of the whole of the accounts. Referring to the capital account, he said they would see that £320,991 had been expended during the year on construction of exchange trunk and private lines. A proper analysis of all their accounts depended upon a factor. Their business was, however, such a changeable one that it was a difficult matter to determine upon a factor. The Directors had exercised their brains a good deal upon the question of the factor by which to measure the value of the service, and they had taken the lines for that purpose, because to take the subscribers would not do. The number of lines during the year had increased by 20 per cent., while the expenses had increased by 18 per cent., charging the lines with the cost of the trunks. The cost of the installation of those lines was £220,000. They could not meet those outgoings which were apart from revenue and maintenance, without raising money, and during the period they had raised a considerable sum. The calls upon the 6 per cent. preference stock had been paid up, and represented £30,000. They had issued a small balance of ordinary stock, amounting to £5,000, and they had increased the debenture debt by a considerable sum. Paragraph 8 of the report opened a very important question, and had thrown upon the Board a most serious responsibility. The Company were universal licensees – that was to say, they had the privilege within the whole United Kingdom of laying down lines, opening exchanges, fixing their own rates, and conducting their business in their own fashion. That was a policy initiated by a man who had considerable claims to statesmanship, namely, Mr. Fawcett, when he was Postmaster-General, in contrast with the earlier policy, which was to limit their licenses and powers. They had gone on for several years spending their money and incurring risks upon the faith of that contract. There was one blemish in the matter, and that was that it was a sufferance, without any legal status or powers. That had resulted in this state of things: that the telephone in England had not advanced in relative user or perfection at all in the same degree as in other countries, where the conditions were different. If they had legal powers to do all the things which must be done in order to make an efficient service, they would have done it long ago, but they were not in that position. For several sessions they had been knocking at the door of Parliament to ask them to let the Company do what the subscribers and public were complaining that they did not do: give an efficient service and extend their business, but the Post Office would not let them in. The Post Office bought a monopoly of telegraphs at a price which made them very comfortable, and the policy of the Post Office in respect to telephones, until lately, appeared to be to leave them to struggle as best they could in the prosecution of their business, but by no means to help them. He did not complain of the Post Office. They had a business purchased at an enormous price, at the risk of the taxpayer – not at the risk of the shareholder – and they were bound to protect their revenue. During last year the Post Office transmitted 66,000,000 telegrams, which cost the public something approaching 9d. each, whereas this Company transmitted 160,000,000 of communications, so to speak, at a price approximating to 1½d. each. The average number of words in those communications meant not 12 words, but 40 or 50. The Company brought a Bill in this session demanding Parliament's attention to the matter, and it brought the question to a head, with the result that the Government determined upon a policy. The policy reversed, to some extent, the policy of Mr. Fawcett; that was to say, the company or the licensee was to be entitled, in areas to be determined by the Government, to carry on the business of exchange, but could not break the bounds except through the Government instrumentality; therefore, a man living in London could not communicate outside a particular area without the Government consent. They knew what that present area was, but they did not know what it was going to be. The Treasury minute expounded the policy, which was very curious. This Company began this business, and had to take all the risks of its imperfections as a new discovery, and all the risks of applying it without legal powers. All this was to be wiped out, and they were to go back now to a limited area. Of course, they had got a very valuable connection in their trunk wires, which supplied the means of intercommunication, and the proposition was that they should surrender that intercommunication, and hand it over to the State. In virtue of that surrender they were to be left in the areas, and to have certain privileges for their subscribers. They might transmit messages by telephone to be forwarded by telegraph; they might call a Government messenger to deliver their telephone message. There were several matters, no doubt, of great convenience and of some value, but the Directors considered that that alone was not equivalent to very much. The surrender of their trunk lines deprived them of just those advantages which the Treasury minute declared to be a menace if left in the hands of a private company. The telegraph and the telephone might be made one to help the other, but the proposal of the Government was a half and half measure. It complicated a thing which might be made simple; it brought it under a dual control; it would not facilitate either promptitude or simplicity, and he was not sure that it would promote economy in telephony. The proper thing for the Government to do was to acquire the telephones, but they did not do that. The shareholders would, therefore, see what a delicate and difficult position they were in. They might now agree with the Post Office to surrender their present concession, which gave them unlimited power as far as they could exercise it, and they might accept limited powers; but they did, in fact, put themselves more or less into the hands of the Post Office. It was true that they need not

agree; but then the Post Office would say: "If you do not agree we will promote people who will agree, and we will afford them the means of trunk communication from one end of the kingdom to the other, and then their competition with you will be a very easy one." The position of the Company was seriously influenced by that consideration, and they had made up their minds that they ought to agree with the Post Office, because as the licensees of the Post Office their relations were so intimate and so dependent upon them in many ways that mere prudence and loyalty would involve their doing everything they could to make this policy succeed; but, of course, they wanted to know what the consideration was to be. The surrender of the trunk wires, which was a *sine quâ non*, meant some important considerations, and the equivalent offered in the Treasury minute would not satisfy them upon the theory of taking the mere cost of the trunk wires, and surrendering their future money-earning value. The whole thing depended upon the Company getting fair terms, and the Directors were now in negotiation with the Post Office. No agreement with the Post Office would be settled without being submitted to the shareholders, because he thought it would be unfair to throw upon the Directors so immense a responsibility as to determine the whole future of the Company upon an agreement, the result of which no man could absolutely and clearly predict. Dealing with the ninth paragraph of the report, he pointed out that Mr. George Franklin, of Sheffield, had been elected a director, and that Mr William E. L. Gaine had been appointed general manager. In conclusion, he moved: "That the report and accounts be received and adopted, and that dividends be paid for the half year ended April 30 last, at the rate of 6 per cent. per annum, less income tax, on the amounts paid up on the first and second preference shares, and at the rate of 7 per cent. per annum, less income tax, on the amounts paid up on the ordinary shares, making, with the interim dividend already paid on such shares, 6 per cent. for the year ended April 30 last."

Colonel R. Raynsford Jackson seconded the resolution, which, after some discussion, was put and carried unanimously.

The retiring Directors and Auditors were re-elected.

At the conclusion of the meeting, the **Chairman** stated that the Board proposed to issue, to the amount of £1,000,000, 5 per cent. preference stock, for the purpose of taking over the Western Counties and South Wales Telephone Company, and it was proposed to allocate the stock *pro rata* to the shareholders. He made that statement in order to ascertain the views of the shareholders on the question, and whether they were disposed to take over the stock.

Mr Faithfull Begg thought the proposal a very reasonable one.

A vote of thanks was then given to the Chairman and Board, and the proceedings terminated.

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY, LIMITED.

The third ordinary general meeting of this Company was held on Monday, at Sheffield. The sum of £795 was added to the reserve fund, and a dividend at the rate of 5 per cent. per annum was declared upon the ordinary shares.

At a subsequent extraordinary general meeting it was decided to reconstruct the Company under the title of the Sheffield Electric Light and Power Company, Limited, having for its object the exploitation and development of the parliamentary powers recently granted to the Company for the electric lighting of a compulsory area in the centre of the town, and also the application of electricity to commercial requirements generally, and respecting which there is a largely increasing demand. The Directors propose to pay off all the preferential shareholders, with interest to date, and to reduce to some extent the capital of the Company, such course being rendered possible by the sale of the Company's telephone exchange.

MANCHESTER EDISON-SWAN COMPANY, LIMITED.

The annual meeting of this Company was held on Monday at the Victoria Hotel, Manchester, Mr. V. K. Armitage, chairman of the Company, presiding.

In the Directors annual report, which was submitted, it was stated that the net profit for the year, including last year's balance, amounted to £2,826 1s 10d. Out of this it was proposed to pay a dividend at the rate of 5 per cent. per annum, which will absorb £1,000 to carry £1,000 to reserve fund, and to carry forward a balance of £826 1s 10d.

On the motion of the **Chairman**, seconded by **Mr W P James Fawcus**, the report was adopted, and the dividend recommended therein was declared payable.

Mr Armitage was re-elected a director of the Company, and thanks were accorded to the Directors for their services.

ELECTRICAL POWER STORAGE COMPANY.

The third ordinary general meeting of the Electrical Power Storage Company, Limited, was held on Wednesday, at 4, Great Winchester-street, E.C.

Mr J. I. Courtenay, in moving the adoption of the report, said that the dividend of 6 per cent. had been earned by the secondary battery manufacturing business at Millwall during the 12 months that had elapsed since the Company took it over from the Electric Construction Corporation. A gratifying increase of business had taken place in that time, and the financial position of the Company was a strong one, there being a balance of nearly £10,000 at the bankers, and current accounts due to the Company of upwards of £11,000, as against about half that sum owing by the Company. The only gold medal presented at the Electrical Exhibition for secondary batteries was awarded to the Company, and was proof of the excellence of their products. A further development of the foreign business, which had been hindered by competitors, was now anticipated.

Sir Daniel Cooper seconded the motion, which was carried.

The retiring Directors and Auditors were re-elected.

COMPANIES' REPORTS.

EASTERN TELEGRAPH COMPANY.

Report of the Directors for the half-year ended March 31, 1892, to be presented to the fortieth half yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, to-day.

The Directors submit the accounts and balance-sheet for the six months ended March 31, 1892. The revenue for the period amounted to £382,207 11s. 4d., from which are deducted £105,820 13s. for the ordinary expenses, and £53,515 5s 1d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £2,979 17s. 6d. for income tax, there remains a balance of £219,900 15s. 9d., to which is added £57,509 7s 1d., brought from the preceding half year, making a total available balance of £277,410. 2s. 10d. From this amount there have been paid.

Leaving a balance of £178,661. 7s. 7d., from which £68,000 has been carried to general reserve. The Directors now recommend the declaration of a final dividend for the year ended 31st March, 1892, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 22nd instant, free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares. The balance of £661 7s. 7d. shown at the foot of the revenue account is proposed to be carried forward to the next half year. The revenue includes £32,791 12s. dividends and bonus for the half year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies. The shareholders having at the last general meeting approved the principle of establishing a staff pension fund, your Directors have had the details worked out by experienced actuaries, and a scheme will be submitted to the meeting for dealing with the matter, together with a formal resolution empowering the Directors to carry out the necessary arrangements.

NEW COMPANIES REGISTERED.

Electrical Company, Limited.—Registered by Michael Abrahams, Sons and Co., 8, Old Jewry, E.C., with a capital of £15,000 in £5 shares. Object: to acquire the undertaking of Keys' Electric Company, Limited, in accordance with an agreement expressed to be made between that company of the one part and this Company of the other part, and to carry on and extend the same in all its branches. There shall not be less than two nor more than five Directors. The first are Messrs. Franz and Felix Deutsch. Qualification not specified. Remuneration, 10 per cent. of the net profits available for dividend.

J. C. Howell, Limited.—Registered by Deacon and Co., 4, St. Mary axe, with a capital of £25,000 in £5 shares. Object: to acquire the business as electrical engineer now carried on at New Dock, Llanelly, and 24, Queen Victoria-street, E.C., by J. C. Howell, and to develop and extend the same. There shall not be less than three nor more than seven Directors. The first are J. C. Howell and W. M. Meredith. Qualification not specified. Remuneration, J. C. Howell, £800, W. M. Meredith, £300, to be raised £50 per annum up to £800.

Theatre Electrical and Specialities Production Company, Limited.—Registered by Heald and Sons, 28A, Leicester square, W.C., with a capital of £5,000 in £1 shares. Object: to acquire the business of Messrs. Gretton, Madgen, and Heald, of 28A, Leicester square, and to carry on the business of caterers for public amusements in all its branches. Table A applies.

Leroni and Bowman, Limited.—Registered by Fraser and Christian, 4, Finsbury-circus, E.C., with a capital of £2,500 in £1 shares. Object: to carry into effect two agreements expressed to be made between V. G. Leroni and J. J. Bowman, and between T. W. and A. J. Hollington, of the first part, and this Company of the other part, for the acquisition of the undertaking of electrical engineers now carried on by V. G. Leroni and J. J. Bowman at Bow, and to develop and extend the same. There shall not be less

than three nor more than five Directors The first are A. J. and T. W. Hollington, V. G. Leconi, and J. J. Bowman. Qualification, £50. Remuneration not specified.

BUSINESS NOTES.

Electric Alphabetic Signals. -A syndicate has been formed to work Mr Kelway's electric signals.

Western and Brazilian Telegraph Company The receipts for the week ended July 15 were £2,559.

West India and Panama Telegraph Company. -The receipts for the half month ended July 15 were £2,091, against £1 973.

India Rubber, Gutta Percha, and Telegraph Works. An interim dividend of 10s. per share has been declared by the Directors.

St. James's and Pall Mall Electric Light Company -The Directors announce a half yearly interim distribution at the rate of 5 per cent per annum.

City and South London Railway -The receipts for the week ending July 17 were £766, against £689 for the same period of last year, or an increase of £77

Direct United States Cable Company.-The Directors of this Company recommend a final dividend of 3s 6d. per share, tax free, payable on and after 30th inst , making, with the interim dividends already paid, 3½ per cent. for the year ended June 30, carrying forward £3,730.

Electric Contractors Messrs. Evans, Stewart, Palmer, and Co. have taken premises at 47, Carnaby street, opposite the St James's and Pall Mall Company's new station, as electric light engineers and contractors. They have already carried out several business installations in the West end.

London-Paris Telephone A call office has been opened, in connection with the London Paris telephone, at the West Strand Telegraph Office, Charing Cross The office will be open day and night, and the charge for telephonic communication with Paris is 8s. for a conversation of three minutes

Anglo-American Telegraph Company —The Directors of this Company have declared an interim dividend for the quarter ended June 30 of 12s 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock, less income tax, payable on July 30 to the stockholders registered on the books on July 11, 1892.

Crompton and Co. —The report of Crompton and Co., Limited, for the year ending 31st March last, states that the net profits amount to £15,068 The Directors propose dividends of 3s. 6d per share on the preference shares, and 1s. 6d. per share on the ordinary shares, both for the half year: they also propose placing £1,000 to the reserve fund.

Globe Telegraph and Trust.—The report of the Directors for the year ended July 18 shows that the net revenue of the Company, after deduction of expenses, amounts to £192,243, and makes, with the balance of £1 876 brought forward, a total of £194,120. From this amount there has been distributed the sum of £133,057 in interim dividends, leaving an available balance of £61,061. The Directors recommend the payment of a final dividend for the year of 3s per share on the preference shares and 3s 9d per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent , less income tax, upon the preference and 1½ per cent. net (against 5½ per cent. for the preceding year upon the ordinary shares, and carrying forward a balance of £938.

Elmore's French Patent Copper Depositing Company. -The Directors invite applications for an issue of 20,500 perpetual 10 per cent preference shares of £2 each, entitled in addition to 5 per cent. (making 15 per cent.) out of the surplus profits after the ordinary shares have received 15 per cent. The 10 per cent interest is guaranteed for the first year by Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited. The shares, with the 13,250 already allotted and the 26,250 reserved for paying off existing debentures, will complete the 60,000 shares authorised by the shareholders at the general meeting. The report of M. Secretan, the general manager, presented to that meeting, showed that the estimated revenue which would be available for the payment of the 10 per cent. minimum dividend on the 100,000 preference shares (of which the shares now offered for subscription form part) was £114,240 per annum when the entire plant is erected, the annual amount required for the 10 per cent. dividend is only £20,000 per annum. To pay the further 5 per cent. after the ordinary shares have received 15 per cent. would require only £10,000, whereas, according to a calculation contained in the prospectus, £64,240 would remain available for that purpose The ordinary share capital of the Company is £200,000, divided into 100,000 shares of £2 each, all allotted.

PROVISIONAL PATENTS, 1892.

JULY 11.

12691. **Improvements in electromagnetic apparatus for controlling electric light and power circuits.** Sydney Ferris Walker, 195, Severn road, Cardiff.

12700. **A new or improved apparatus for carrying or conveying telegraph or telephone wires over houses or buildings** David William Peaks, 30, Newland, Northampton.

12731. **Improvements in electrolytic extraction of zinc** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

12735. **Improvements in supports for telegraph insulators** John Crisp Fuller and George Fuller, 33, Chancery lane, London.

12737. **Improvements in electrical switches and incandescent lampholders.** Thomas Jenner and George Beckwell Wilkes, 77, Chancery lane, London.

JULY 12.

12745. **Electric signalling apparatus** Herbert John Allison, 52, Chancery lane, London (The Standard Electric Signal Company, United States.) (Complete specification

12759. **Improvements in or relating to electric railways especially those in which underground conduits are used, and in rolling-stock for the same** William Phillips Thompson, 6, Lord street Liverpool (Arthur B Hieatzman and Harry D Hieatzman United States.

12807. **Improvements in apparatus for regulating the arc in electric arc lamps** Alfred William Money and Herbert Nase, 23, Southampton buildings, Chancery lane, London

12818. **Improvements in conduits for electric railways** Edward Evans-Jackson, 45 Holborn viaduct, London (Charles Dibbie Comstock Huestis, United States.) (Complete specification.)

JULY 13.

12888. **Improvements in electrical regulating devices for clocks** Ludwig von Orth and Emil Breslauer, 323, High Holborn, London. (Complete specification.)

JULY 14

12906. **Improvements in and relating to "roses" or electrical connections for the ceilings of buildings or structures** William Martin Haddow and John Smith Hutcheson, 8, Buchanan street, Glasgow.

JULY 15.

12977. **Improvements in the electrolytic production of caustic soda or caustic potash.** Charles Anthony Burgess, Fountain street, Manchester.

12999. **Improvements in the method of and means for distributing electric currents.** Gisbert Kapp, 70, New street, Manchester.

JULY 16.

13072 **Improvements in coupling and fixing glass tubes for containing electric wires** Dan Rylands and Sidney Nash, Shepcote, Barnsley.

13090. **Improvements in portable electric lamps and also fuses for same** Killingworth William Hedges, 8, Queen's court, Chancery lane, London

13095. **Improvements relating to the electric heating of pottery and other furnaces and materials therefor** [illegible] von Poschinger, 18, Buckingham street, Strand, London.

SPECIFICATIONS PUBLISHED

1881.

4428 **Telephonic apparatus** Bennett. (Second edition.)

1890.

9125 **Telephonic apparatus.** Kingsbury (Western Electric Company). (Second edition.)

1891

12416. **Telephonic receivers.** Marr.

12585. **Electric switches** Newton. (Swan.)

14083. **Telephonic transmitters** Marr.

1892

9380 **Converting electric currents** Burton.

9541. **Electric accumulator.** Schmalhaus

9863. **Electric signalling apparatus** Lake (The Electric Secret Service Company).

Hanley.—At the monthly meeting of the Hanley Town Council last week, the borough surveyor was instructed to prepare a report on those tenders for electric lighting which utilise a site on the canal side for the central generating station, and to obtain from the different firms tendering for the street arc lighting in the above class such explanations and prices as would enable them to be placed on an equal footing.

Holbeach.—At a special meeting of the Holbeach (Lincolnshire) Local Board last week, the question of street lighting was considered. The tender for gas lighting was 40 and for electric lighting 80 per cent. more than oil. The tender for oil-lamps was accepted, though the inhabitants had petitioned in favour of gas. The streets used to be lighted by gas until a dispute arose with the gas company in consequence of the high charges made.

Motors.—Mr. Keeley is out of it. Another comprehensive inventor, Mr. S. H. Woods, of Minneapolis, has, we are told, arisen: he has invented a motor that is "cheaper than steam, electricity, or any other power at present in use." Of course the invention is (as yet) secret, but investors are invited to send up their dollars at once. Energy is to be taken from the blue sky by Mr. Woods, and mills, elevators, cars, and railways are to be driven!

Cardiff and Swansea.—The *South Wales News* complains that nothing yet is being done in the principal towns of South Wales to introduce the electric light. It suggests public spirited policy by the local authorities, and the consultation of Prof. Kennedy or Prof. Hopkinson, or other consulting engineers unconnected with any particular system, upon whose recommendation it is time to take action. "We have waited," says the *News*, "already too long for the adoption of electricity in South Wales.

Cork.—Said the chairman of the Standing Committee of the Cork Town Council last week: "The sooner we get electric light into the city the better for ourselves, and get rid of the gas company." Mr. Giltman said the gas company intended to ask the Corporation at the next meeting of the Council to consider their intention to ask the Board of Trade for authority to supply electrical energy. The chairman hoped every member of the Council would reject it, and that the Corporation would take over the lighting themselves.

Chicago.—The Westinghouse generators for the 93,000 16 c.p. lamps at the World's Fair are to be "the largest in the world." One of the dynamos will supply 20,000, and most of the others 10,000 each. Several Indian princes, with their retinues, have decided to visit the Chicago exhibition. Two of the original guns used on Columbus's flagship have been secured, and will be exhibited. It is hoped that the original apparatus fitted by Sir William Thomson at Valencia to transmit the first Atlantic cable message will be sent from England to the exhibition.

Electric Bullseye Lanterns.—A novel experiment has been tried this week, we learn, by the London police force in the substitution of small electric lamps for the ordinary oil bullseye lantern. The new venture has proved highly satisfactory. The electric lamp weighs 4lb., and is guaranteed to give a continuous light for seven hours. The tramway companies are also taking the matter up with much interest, with a view of permanently adopting electricity for lighting. Possibly the solution of train lighting will be rather by these storage lamps instead of the dynamo fittings on the train.

Lighthouse Communication.—The Royal Commission on electrical communication with lighthouses and lightships met again on Thursday last week, the Earl of Mount-Edgcumbe presiding. After considering the proposed methods of establishing communication by telegraph with lighthouses and lightships on the Scotch coast, the Commissioners arranged to go in the autumn on a tour of inspection. This will commence in the latter half of August at the Goodwin Sands and the mouth of the Thames. Visits will also be paid to Cromer, the Bristol Channel, and the Scilly Isles.

Crystal Palace.—The report of the directors of the Crystal Palace Company shows an increase last half-year of £5,735 in receipts, and £2,645 in expenditure, attributable to the electrical exhibition. It is a matter for regret that it did not prove more attractive. Notwithstanding the miles of cables and the high pressure in many cases employed, there has not been from first to last the smallest indication of fire. This may be attributed, we think, to the great care given by Mr. Heaphy to the arrangements. The extra £600 paid, it will be remembered, for insurance, was thus clear gain to the companies.

Eickemeyer-Field Motors.—M. Rudolf Eickemeyer was born in 1831 in Bavaria, being educated at the Polytechnic Institute of Darmstadt. He and Mr. Osterheld started a works in Yonkers before the Civil War, but he has since allied himself to Mr. Stephen D. Field, a nephew of Cyrus Field. The two have been very active in electrical inventions, Mr. Eickemeyer claiming early work in the alternating-motor field. He has other good things in store, but his latest success is the Yonkers electric railway, the cars being fitted with single gearless motors of [illegible] h.p., which run with great satisfaction.

Welding Rails.—The electric welding of street railway rails, as a substitute for fishplates, has been the subject of experiment in engineering shops in America for some time back. The process is said to be entirely successful. It is found possible to weld by electricity two pieces of steel of 25 square inches section, and therefore a solid rail four or five miles long can be produced if required. An interesting point to notice is that the tests are also said to prove that the necessity of joints to provide for contraction and expansion is not so apparent as engineers have supposed, though the data upon which such a result is based are not given.

Telephone v. Tramway.—The action between the National Telephone Company and the Leeds Electric Tramway Company (Mr. Graff Baker) has, we fancy, gone too far to be stopped by an impartial enquiry by the Chamber of Commerce. It is to be hoped that a good sound precedent will be established one way or the other. The question has gone through all the stages in America and on the Continent, where the Courts have decided that the streets being built for carriages to run upon, the tramways have the right to use the earth return if they desire, and so have the telephone companies—if they like to do so and find they can.

Chiswick.—The Chiswick Local Board obtained some time ago its provisional order under the Electric Lighting Acts. Absolutely ignorant of its value, they now propose to transfer their powers to Messrs. Bourne and Grant for £600 in cash. But that is not all. They propose to lease these gentlemen a magnificent site for a station for £1 per annum. Naturally, those of the inhabitants who know anything about electricity are much dissatisfied, and steps are being taken to memorialise the Board of Trade to refuse its sanction to the arrangement. The issue of the Chiswick Electric Lighting Company, Limited, is likely, therefore, to be postponed for the present.

The Tivoli Transmission.—A correspondent of one of the Italian papers gives an interesting account of

his recent visit to Tivoli, where the transmission of electricity from that town to Rome has now been inaugurated. In the transmission of the power the loss is very small, being reduced to 20 per cent. in all. With regard to the distribution of energy, it has been proved that at a small cost this can be increased so as to provide Rome with electric light, not only for public illumination, but also for public industries. The six turbines, the motive power of the work, represent 2,000 h.p., and are placed at the base of an enormous tower of masonry, which conceals the cascade, and which is supported by the ancient wall that surrounds the town.

Japan.—As one of the markets of the world, Japan offers many advantages. For one reason its inhabitants are determined to progress and to introduce all the latest developments of Western civilisation. The progress made in electrical matters is astonishing—the Tokio Electrical Society has, we are told, already over 12,000 members. There are now 1,014 telegraph offices, and Tokio numbers over 1,000 telephone subscribers. Tokio and Osaka are connected by a telephone line, 350 miles long. Two electric railways, 12 and 17 miles long respectively, are under contemplation. A Japan Society has recently been formed in London, and we notice that members of some electrical firms are joining—a wisdom of the serpent that commends itself from the point of view of "foreign markets."

Air Condenser.—An interesting departure is to be made in the Dundee central station, in the shape of the use of what is known as an air condenser instead of a water condenser. The exhaust steam is led along a series of pipes, the outsides of which are exposed to air, and further kept cool by water trickling down the sides. This arrangement must not be confused with the air cooler used at the St. Pancras installation, in which the hot water is cooled by exposure to the winds of heaven after having been condensed by the ordinary water-spray condenser. The engineers to the Dundee installation are Messrs. Urquhart and Small, Westminster, by whose advice the air condensers are being adopted. The contract for the pipes, we believe, has not yet been actually decided waiting this extension.

Electric Locomotives.—"It has yet to be proved," says the *Engineer* in an article on electric locomotives, "that it is possible to make an electric motor which will comply with all the multifarious conditions inexorably dictated by the exigencies of traffic. In the United States nothing of the sort has yet been produced, and it is fair to assume that they know as much at the other side of the Atlantic as is known at this about electricity. Apparently a very wide departure from existing methods and principles of construction may be needed to secure success, and no one can say that the field of invention in this direction is nearly filled. It seems, however, to be almost time that someone with the requisite knowledge and ingenuity set himself in earnest to the work of designing a real electrical locomotive."

Electric Dairy.—Mr. James Blyth, nephew of the famous breeder, Mr. Walter Gilbey, has gone in for extreme advance in his new dairy at Blythwood, where electricity is used as motive force. Mr. Blyth and his architect visited all the best dairies on the Continent and at home, and also took the best advice as to machinery and utensils. The result is a half-timbered Jacobean structure of red brick and oak, with a Carrara marble dairy in the basement. The building is fitted throughout with electric light, and all the motive power for separators and churns is supplied by electricity. The opening was performed on Saturday by the Lady Mayoress, in the presence of a very distinguished company, and doubtless marks the beginning of a considerable extension of scientific dairying in which the dainty goddess Electra, as in so many other fields, will play an important part.

Waterford.—So far the electric light is saved for Waterford. A motion was brought forward before the Electric Lighting Committee at the last meeting to the effect that the lighting should be handed over forthwith to the gas company. On the strenuous bringing forward by the Mayor and Alderman Ryan of the facts that the provisional order, which had cost £400, would be lost, and that the lighting by electricity now saved £1 a lamp—a total of another £400 a year—the motion was successfully resisted, but only by the casting vote of the Mayor. The Corporation have only just saved themselves from the imputation of unfairness and jobbery, and it is to be hoped that the question of public lighting of the principal streets will now be put on a proper basis, with the reversion of the plant to the municipality after the due number of years.

Electricity in Collieries.—The owners of the Ashington Colliery, for whom Messrs. Ernest Scott and Mountain, Limited, of the Close Works, Newcastle-on-Tyne, have recently supplied an installation consisting of one of their Tyne compound-wound dynamos, capable of running 100 16-c.p. incandescent lamps, together with lamps, etc., which has given every satisfaction, have decided to extend their installation, and have placed the contract for the extension, which consists of a 400 light dynamo with lamps and fittings, in the hands of the same firm. Messrs. Scott and Mountain have recently completed a large electric light installation for the Birtley Iron Company, comprising a vertical engine and Tyne compound-wound dynamo to run 200 16-c.p. lamps. We understand that Messrs. Ernest Scott and Mountain are making a speciality of electric pumping and transmission of power installations for colliery purposes. They have recently introduced several novelties, and are about to issue a new catalogue illustrating this kind of machinery.

Phonograph Dynamo.—Although the phonograph has been objected to for the alleged reason of its being a toy merely, and because the listener does not hear corrections until after the sentence has been given, yet we notice it seems to be coming into use in business offices in New York. Mr. Erasmus Winans considers it "even more valuable than the typewriter." It is used in the offices of our New York namesake, and is said to be "always reliable," even at 300 words a minute. We allude to this instrument because of the introduction of a new toy dynamo brought out by the Eastern Electric Light and Storage Battery Company, of Lowell, Mass., used to charge the two storage cells for driving the phonograph. These dynamos are small enough to be carried in a satchel, and can be run by a cord from any convenient engine or shaft that happens to be going, and give 15 amperes for charging. The cells take 150 ampere-hours, and a gelatine electrolyte cell is now being employed. Such a set of dynamo and cells might be useful for other purposes—such as mining inspectors' lamps.

Niagara Falls.—We see it stated that Prof. Unwin, of the City Guilds College, has been offered £5,000 a year to undertake the duties of engineer-in-chief to the Niagara Falls Company, who intend shortly to utilise and distribute half a million horse-power. The company seem to be determined to have the best advice obtainable. Lord Kelvin, Colonel Turettini (engineer to the Geneva works), Prof. Forbes, lately Mr. Edison, and now, if it be true, Prof. Unwin, have been invited to join forces with Nature at this problem. Mr. Tesla, also, is on his way back to the States to do his quota in the distribution problem, and Mr. Ferranti, we have all heard, has early had a hand in this stupenduous undertaking, which certainly has a fascination entirely its own to engineering minds.

The works at the Falls are progressing rapidly, over 100,000 bricks being laid per day towards completing the tunnel, 1½ miles long, which is to lead the water from above the Falls to the turbines at the rapids. Chicago may yet achieve her darling wish, and receive power by wire from Niagara.

Weybridge.—A public meeting was held by the inhabitants of Weybridge last week to meet Colonel Martindale and other directors of the Laing, Wharton, and Down Syndicate with reference to the electric lighting. Colonel Martindale explained that they had intended to go on quietly building up a business, but that the Board of Trade had insisted on certain things which necessitated heavier expenditure than they could undertake alone. They proposed to take payment for the present plant at cost actually expended—£7,000—in shares of a new company; to do the necessary work in putting wires underground for a further £7,500, half in cash and half in shares, the Weybridge Company also to pay £1,500 cash on account of registration and expenses of formation and cost of provisional order. It was ultimately resolved to ask the following gentlemen to act as a committee to meet the directors of the syndicate and discuss matters: Captains Hawes and Bax, and Messrs. Verity, Benson, Ward, Young, Vardy, Palmer, and Drs. Sealy and Powell.

High-Tension Accidents.—The recent reports of the recovery of patients struck by lightning after two, four, or eight hours' treatment for asphyxiation, have called the attention of medical men to this question. Dr. Lacassagne, of the Faculte de Medecine of Lyons, has issued a pamphlet, in which he prays all who have had to do with accidents to human life from high-tension currents to fill in full particulars to his circular of questions, the answers being treated as private when desired. The questions deal with part of body touched, potential, earth or short circuit, whether victim dropped or was pulled off, sensations, treatment adopted, whether burns, difficulty of walking, of breathing, of seeing, headache, sciatica, etc., as results; duration, effect on sleep, etc., dynamo or transformer current, and so forth. Copies of this circular can be obtained, and for the sake of the medical faculty, everyone who has seen or experienced such an accident should endeavour to fill in the particulars. Above all, they should remember that careful treatment for artificial respiration by movements of arms, hot flannels, jerking the tongue, should be persisted in for hours, and will probably result in the saving of life.

"Old America."—Such is the name of the attraction that rules at Manchester; in other words, an exhibition is now being held in the Botanical Gardens at Manchester at which a street to represent Old America plays a conspicuous part. More conspicuous still is the representation of the old Eddystone lighthouse, removed from the Naval Exhibition. The revolving beams from the lighthouse tower are eagerly watched in and around Manchester as they ever were in London. The grounds and buildings are electrically lighted, the work being in the hands of Messrs. Siemens. Two 300-h.p. units are used at night, a smaller plant being used in the daytime. The boilers are by Galloway; the engines are the well-known Willans central valve, and the dynamos and all the lighting appurtenances are by Messrs. Siemens. At a visit paid to the installation last Saturday, everything was found in apple-pie order. Messrs. Siemens have gained a great reputation for excellence of work, and when it is considered that the whole of this installation was completed within a couple of months of receiving the order, great credit must be given to those into whose hands the duty of putting up the installation was placed.

Electric Light in Colleges.—The electric light was turned on last week to the dining-hall in Magdalen College, in the presence of the president of the college, the vice-president, and Messrs. A. D. Godley, E. M. Miller, C. H. Turner, and C. C. J. Webb (Fellows), also Mr. A. Hassell and Mrs. Hassell (Christ Church). There were also present Mr. Selby-Bigge, director, and Mr. J. H. M. Lean, engineer to the Oxford Electric Company. The hall has been fitted with 76 lamps of 16 c.p. each fixed on brackets arranged round the hall, six lamps on each bracket. Two ornamental upright brackets are fixed on the gallery, with a cluster of a dozen lamps on each which have a very pretty effect. The effect was very brilliant, and the president and all the college authorities who were present expressed themselves highly satisfied. Brasenose and Hertford Colleges are being fitted with the electric light throughout, and both places will be completed in a few weeks. Brasenose will have lamps amounting to an equivalent of over 700 8-c.p. lamps, and Hertford an equivalent of 400. The Oxford Company are about to lay a considerably larger number of underground mains in different streets to cope with the demand which is arising for the light.

Coventry Tramways.—Mr. W. E. Graff Baker, who has purchased the undertaking of the Coventry and District Tramways Company, has made an important proposal to the Coventry City Council. Addressing that body as the principal local authority on the route of the tramways, which extend from Coventry railway station to Bedworth—a distance of about six miles—he proposes that it shall, with the concurrence of the other local authorities, purchase the entire tramway lines, and all the various parliamentary powers in connection therewith. He further proposes that the Council shall give him a lease of the lines for a period of 21 years, with liberty to assign with the Council's approval. The price to be paid to him is to be £12,000, Mr. Baker at his own cost to relay the paving on the line of route and the copper wire thereunder, which will be used in the operation of the road by electricity. Mr. Baker, under the lease, is to pay a rent of £840 per annum, payable in advance, which, by the end of the lease, will cover the amortisation of the principal—the cost being thus written off; the Council, however, to be responsible for the maintenance of the lines. Should the proposition meet with approval, Mr. Baker will at once put down the necessary plant and equipment for the operation of the tramways by electricity at regular and frequent intervals, and one of his banks is prepared to advance the sum of £12,000 necessary for the purchase of the tramways, should the Council require it, for 21 years at 3½ per cent.

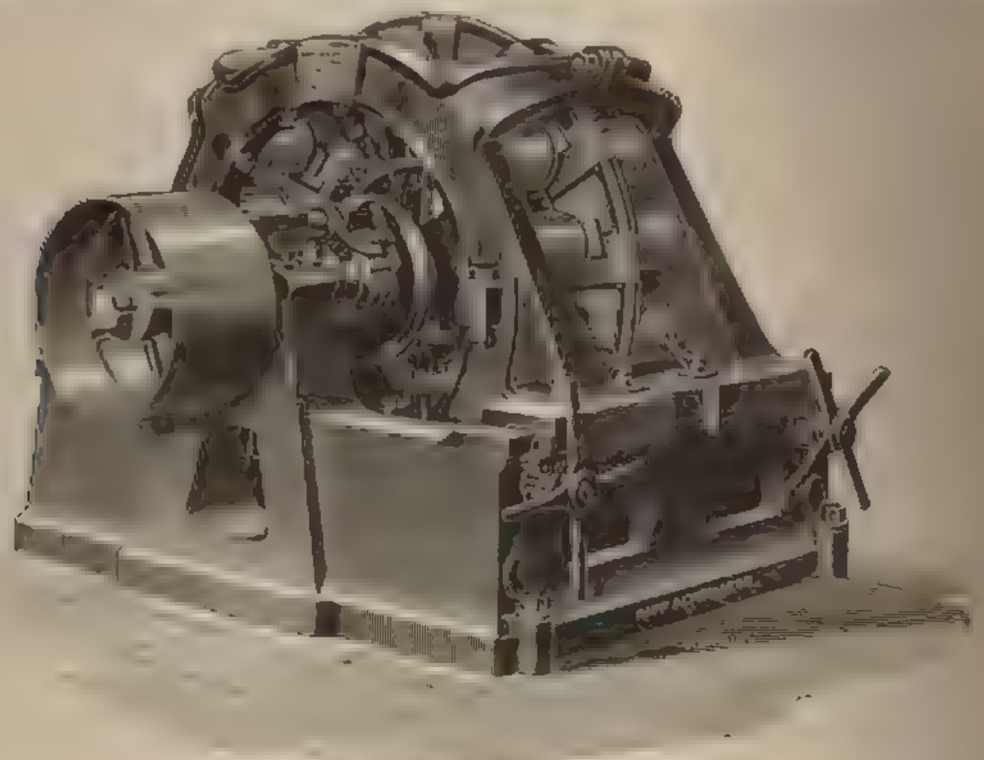
Dublin.—In the early hours of Wednesday morning the principal streets of Dublin were illuminated for the first time by the electric light. The run was made as a test, and was remarkably successful. The light was exceedingly bright and steady, and was a brilliant contrast to the dull and flickering gas jets which were still unextinguished. The appearance of the city under electric light was as if daylight had suddenly broken in upon the darkness before its time, and the officials of the Corporation and the contractors feel the greatest satisfaction in the result of the trial. "For more than an hour," says a correspondent, "the electric light reigned supreme, and it was a great pity that the trial should have taken place in the early hours, when the people were prevented from witnessing the effective working of the system. When the engines were stopped, and gas again shed the

ALTERNATE-CURRENT DYNAMOS.

BY R. W. WEEKES, WHIT.SCH.

Messrs. Johnson and Phillips.—The Kapp alternators made by this firm complete the list of those having moving armatures and fixed magnets. The arrangement of the field magnets is different from the two last described, as the opposite poles have in this case the same polarity. The magnetic lines of force pass from one magnet to the next on the same side of the machine through the iron core of the armature. So, though a set of poles is required on each side of the armature to give magnetic and mechanical balance, yet the magnetic lines generated by the set of poles on each side of the armature are distinct in their action.

The mechanical construction of the field is briefly as follows: The magnet cores are made of wrought iron, and inlet into cast-iron frames, as seen in the illustration. Cast-iron pole faces are screwed to the cores after the exciting coils have been placed in position. The pole face is made nearly rectangular, so that there shall be an equal number of lines of force entering the armature core at all distances from the centre. This is to prevent as much as possible the flow of lines from one lamination of the core to the next, which would produce eddy currents in the iron. The cast-iron frame into which the cores are fastened is made in two halves, and bolted together to facilitate the removal of the armature when needed. In the large machines, each ring of magnets is arranged to withdraw along the axis of the armature by means of a rack and pinion gear to enable the armature to be examined *in situ*. The armature core is built up by winding charcoal iron strip of the full width of the core on to a cast iron spider ring till the desired depth is obtained. The number of arms in the spider is half the number of poles in the machine, so that two coils are wound in each space between the arms. The outside of the core is then made up with hard wood to the desired contour where the coils have to be wound. The wood blocks all round are secured in position by driving bolts, and bound on by means of steel wire wound in the circumferential groove left for this purpose. The coils are direct driven by means of shoulders on the wood and the spider arms. The core is insulated with mica and two layers of vulcanised fibre when the conductor has to be wound, and the cast iron spider is fitted with ebonite caps where needed. In this machine the armature conductor has to be wound in place, and in case of damage a coil cannot be replaced, but has to be rewound. The makers claim that the construction of the armature is so strong and the insulation so well looked after that the armature coils do not get loose or burn out. In the small machine exhibited all the armature coils are connected in series, but in the larger central station alternators the two halves of the armature are connected in parallel to reduce the voltage between any two adjacent coils. The conductor used is circular wire in the smaller machines, but in the large 120 kilowatt alternator two thin strips, viz. by ·230in., are wound on edge and connected in parallel. The connections are made to bolts in the spider ring which are well insulated from the spider itself. The current is collected by ordinary copper brushes, of which there are



Johnson and Philips 120-K.W. Alternator

Johnson and Phillips 30-K.W. Alternator

two to each collecting ring. This ring has its collecting surface vertical, and not horizontal, as is the case in the other alternators. This is done to enable the collector to be placed well inside the magnet frame, so as to render the dangerous parts inaccessible to a casual passer by. The magnet poles are inlet into a sheet brass ring, so that

larger than that of the wrought iron, and the spaces so left at the ends are filled in with wood, which forms the insulating support for the armature coils. These coils are wound flat on wooden cores, and then laid on the inner surface of the wrought iron with a sheet of insulating material between. Another wooden ring at each end keeps the coils in position, and securely clamps both the wooden core and the conductors. This ring is made in segments, so that when it is necessary to take out a coil, one segment only need be displaced. On examining the machine when not at work it will be seen that the breadth of the wooden cores is about equal to twice the breadth of the winding. Thus on the armature surface the cores and the conductors occupy equal space alternately, as shown in Fig. 4. The connections between the armature coils are made in the channels cast in the frame (Fig. 3). There are spaces left in casting for the conductors to come through, and the joints are well protected by the lagging of wood. As the armature is fixed, the two ends, after all the coils are connected in series, are led to two terminals, which also are usually placed under the wood lagging. This ensures that no dangerous shock can be got from the machine, as the high tension parts are inaccessible. The insulation of the armature is well carried out, and should give no trouble. The hysteresis loss in the iron is likely to be higher than in the machine last described, as more iron is needed, but there will be very little fluctuation in the field as the armature iron circuit is uniform. The magnets are excited from a 100-volt circuit, and take 16 amperes; thus 5·3 per cent. of the total power given out is required to excite the field. This high value is due to the design and the small size of the machine, as the radial form of magnets does not allow much space for winding when the diameter is small. The mechanical details of this alternator are well designed and carried out, and should give little trouble.

The details of the 30-kilowatt alternator exhibited are as follows: Output, 1,000 volts, 30 amperes at 600 revolutions, 60 complete periods per second, weight complete, 2 tons 15cwt.; floor space, 4ft. 6in. by 4ft.; height, 4ft. 4in.; armature, 36in. diameter, 6in. active length; conductors, ·015 square inch section, wound in 12 coils of 34 turns each; 12 poles of wrought iron, 3in. by 6in.

UTILISATION OF WATER POWER.*

BY HERBERT G. COALES, A.M.I.C.E., ENGINEER AND SURVEYOR TO THE MARKET HARBOROUGH LOCAL BOARD.

It has occurred to the author many times that the utilisation of water power has not received the amount of attention at the hands of the association to which it is entitled—indeed, he can find no paper bearing upon the subject. By placing a few notes before you it is hoped that the recital of your experience and suggestions may be conducive to the further utilisation of water power in the service of our towns and districts. The author casts the responsibility of this paper upon the association, because no more experienced member has hitherto introduced the subject.

In using the term water power it must not be understood that of itself water has any power any more than a spindle has—but it is necessarily acted upon by the energy of gravity, and being practically incompressible, is capable of transmitting power. It is only in this sense, therefore, that the term is used. If municipal engineers would take the trouble to investigate the available amount of water power in their localities for the purposes of applying it for the benefit of their districts, probably not a little advantage might be gained in many directions. Members of this association who have already requisitioned water power for municipal engineering, would confer a great benefit on some of us by narrating the details and efficiency of such work. Our subject has practically nothing to do with the application of machinery to water, but that of water to machinery, except in so far as reference is made to hydraulic mains, having an artificial head caused by the pumping of water under a load into mains, which in turn are to be used for motive power. Doubtless a convenient course will be to classify the subject under three heads: I. Sources of energy. II. Water motors. III. Application of power.

I. Sources of Energy.

Water is a source of energy which, unlike that of coal, is unaffected by strikes; neither is it a power which is ever likely to be more limited than it is at present. Vapour having been raised by the sun's heat, clouds are formed at various distances from the earth's surface. The rain falling from these clouds provides a power which it is the privilege of man to utilise. The higher the elevation of water above the sea-level, the greater the source of energy obtainable. When we consider that falling water is capable, theoretically, of performing just the amount of work which would be required to raise it to the height from which it has fallen, we can understand what an enormous available power exists in nature for the working of machines. When water falls freely its descent will be accelerated in the same manner as that of falling solid bodies. It is, nevertheless, seldom that direct advantage can be obtained from this law, as most of the water falling upon the earth's surface sooner or later finds its way to channels and streams, the inclinations of which are flat and the beds rough, causing great friction. Wherever there is water there is power, and if we remind ourselves that about 3,000 tons of water fall on every acre of area in England per annum, we see that there is no insignificant power which it is our duty to press into the service of man. Evidently only a proportion of the water can be profitably employed as a motor, as the fallen rain has to serve other purposes in nature. But, on the other hand, water can be used over and over again, being unlike steam in this respect, which, on leaving the cylinder, is evaporated. Perpetual motion is a demonstrated impossibility, but in a constant supply of flowing water, as in some stream which is never dry, we approach very nearly to the long sought-for discovery.

It has occurred to the author that besides the power to be obtained from rivers, streams, waterfalls, lakes, tides, etc., small motors might more generally be driven from the water mains, sewage water, storm water, etc. In Market Harborough the pressure in the water mains is sufficient for working such machines as hydraulic lifts, there being a head of 200ft. This head is not sufficient for giving a proportionate efficiency as compared with steam for all purposes, but such a head might be utilised where the employment of other generating power would be out of the question. Mr. J. W. Sutcliffe, in the *Proceedings* of the Institution of Civil Engineers, says, "Every square mile of freely drained area of watershed in this district (East Lancashire and West Yorkshire) will furnish 0·2 h.p. per foot of fall (with very little storage), except during a few weeks in summer, when steam machinery is in its state of maximum efficiency." To take the greatest known source of water power in the world, we are told that the Falls of Niagara has a total descent of 334ft., and discharges about 40,000,000 tons of water per hour; giving a horse-power of over 15,000,000—a power which it is difficult to conceive. At Bellegarde, at the confluence of the Rhone and the Valserine, on a fall of 40ft., 3,700 h.p. are utilised by six turbines. With respect to tidal power, the result of opinion of a discussion at the Yorkshire College Engineering Society appears to have been that it had been somewhat over-estimated. The greatest possible advantage derived from each acre of water 10ft. deep, reckoning a working day at eight hours, was stated to be 3¾ h.p.

An example of unemployed water power may perhaps be here given. Eight years ago the author visited what was then, and is probably now, some disused machinery at St. Germains, in Norfolk. The works were constructed for the purpose of draining low-lying land a few miles from King's Lynn, which is, as you know, at the mouth of the River Ouse. A channel was cut from the Ouse for a distance of 11 miles south of King's Lynn, and at four miles from the town a huge dam was thrown across the channel for the purpose of preventing the tide from flooding the low-lying country on its south side. At low tide it became necessary to liberate the accumulated water on the south side. To this end a series of 16 syphons, 3ft. in diameter, were conveyed over the dam, and protected from the damaging effects of drifting ice and timber by a large

* Paper read at the annual meeting of the Incorporated Association of Municipal and County Engineers at Bury, July, 1892.

with other waterwheels. Gear for increasing the driven speeds with ordinary waterwheels is dispensed with. The first cost of turbines, except those for very low falls is less than for ordinary waterwheels, made in iron, of corresponding power. Where the fall of water is small they yield a better, but where it is great, a worse result than the other wheels. Where, however, the fall is more than 40ft., ordinary waterwheels cannot as a rule be conveniently used, while turbines can be used for falls of several hundred feet. Turbines are, therefore, best adapted for small and very great falls, and the ordinary waterwheels for moderate falls of water.

Jonval's low-pressure turbines are suitable for falls of 30ft. and under. They are either fixed in pentroughs, or inside a close case, according as the fall is great or small.

The effective horse-power of turbines = $\cdot079\,Q\,h$. Quantity of water in cube feet per second = $12\cdot6\,\frac{\text{H.P.}}{h}$.

The volume of many streams could be increased by leading smaller streams into the one channel, should an increased power beyond that existing be necessary. Under many conditions the water, after leaving the turbines and other motors, would flow on without in the least interfering with the existing rights of millowners and others.

Hydraulic Ram.

Hydraulic rams are used for the raising of water only, and are actuated by the weight of the water which they have to raise, or other source of energy—such as sewage water. The useful effect is nil when the lift reaches 26 times the fall, and no delivery can then be expected. The lifting capacity of hydraulic rams is very small comparatively, and as they do not provide motive power, municipal engineers can find little use for them. The effective horse-power of the ram = $\cdot00113\,Q\,h$. Quantity of water used in cube feet per minute = $\frac{881\text{ H.P.}}{h}$.

Water-Pressure Engine.

Water may be brought to act upon the piston of an engine in precisely the same way as steam acts in a steam engine, the pressure being according to the head of water utilised. There is a considerable loss of energy in the flow of water due to friction, consequently a water pressure engine must be run at a much less speed than a steam engine, the frictional losses of energy in a fluid being proportional to its weight. A steam engine has a piston speed of 400ft. or 500ft. per minute; a water-pressure engine rarely has a speed exceeding 60ft. per minute. It is just when an exceptionally high pressure can be obtained, or requires to be used, that the water-pressure engine is most applicable. One of the drawbacks of this type of engine is that the same amount of energy must be expended each stroke whether the load is heavy or light. These engines work with good efficiency when the fall and lift are constant, and when quite proportioned to the work to be done. The effective horse-power of a water-pressure engine = $\cdot00151\,Q\,h$. Quantity of water in cube feet per minute = $\frac{661\text{ H.P.}}{h}$.

Hydraulic Mains.

Bramah, in 1796, by an ingenious contrivance, first gave the principle of the hydrostatic press a practical application. He saw that the incompressibility of water formed a favourable medium for the transmission of force, and it was utilised by him by means of a small pump at a high pressure, acting with the least possible loss by friction on a large piston or ram, thus obviating the necessity of gearing. It was not, however, until 50 years after this that water pressure was utilised in other directions for power purposes. In 1846 Lord Armstrong erected the first hydraulic crane at Newcastle Quay, since which date numerous and valuable machines driven by water pressure have been invented. Lord Armstrong, Mr. Ellington, and Prof. H. Robinson were the first to inaugurate the laying of high-pressure water mains in towns for the purpose of providing power for the use of private consumers, without their having to separately erect the generating plant necessary for causing the required artificial head. The author here begs to acknowledge that much of the information contained in this paper is obtained from the experience of these gentlemen, and also from Prof. Unwin. Hydraulic mains have been laid in Hull, London, Birmingham, and other towns, side by side with gas and water pipes. The most economical pressure to use appears to be about 800lb. to the square inch, which is generated by steam engines pumping into the mains and accumulators.

The accumulator, which fulfils most important functions in connection with the mains, may be described as a cylinder in which a ram works, the top of which is weighted to the required pressure. This weight, which is raised as the piston ascends, of necessity gives the water an artificial head, equal to a column of water of great height. If, for instance, the pressure within the main is 800lb to the square inch, it is the equivalent of a column 1,848ft. high, which, for practical purposes, in most instances it would be almost impossible to obtain. Besides serving to produce an artificial head, the accumulator also stores up the water pumped when it is in excess of the water consumed, and, in fact, performs in the hydraulic system the functions of the flywheel of a steam engine. As the consumption of water by the machines connected with the main falls below the supply of water pumped by the engine, the ram rises and stores in the cylinder the excess, until the ram has risen to the top of its stroke, when it cuts off the steam from the engine by closing the throttle-valve. On the other hand, when the consumption of water by the machines is greater than is being supplied at the time by the engine, the ram falls and supplies the deficiency, at the same time opening the steam throttle-valve by which the full power of the engine is brought into operation. The accumulator thus acts as a reservoir of power and as a conservator of its distribution.

Prof. Unwin writes concerning the power to be obtained from hydraulic mains, "The pressure is too great to be conveniently applied in a turbine, and the pressure engine in its ordinary form is too extravagant in its consumption of water for ordinary power purposes."

Without going into the relative advantages of the various types of pressure engines, we may mention that the Hastie, the Brotherhood, and the Pelton are being used in London for power purposes. These machines have an efficiency of from 80 to 85 per cent. The Chester Hydraulic Engineering Company (who constructed the hydraulic machinery used by the London and Hull Hydraulic Power Companies) state that they have recently fixed in London, besides a large number of Brotherhood hydraulic engines, several Pelton motors. This is a high-speed motor and has a little greater efficiency than the Brotherhood. For slow driving or for machines which require to be frequently stopped and started the Brotherhood engine is the best, but for high-speed machinery, such as for driving dynamos, the Pelton is recommended as there is no necessity for intermediate gearing, and the full power of the motor is utilised.

Possibly, as motive power is not a necessity to people in the same sense as drinking water is, it will be some time before municipalities undertake the installation of power mains themselves, but that it may some day be the duty of municipal engineers to lay them down is not unlikely.

III. Application of Power.

In many directions there is undoubtedly a field for the utilisation of water power in conjunction with that of electricity. A great deal of water runs away year after year unused, to the sea, which might be the motive power for driving electromotors, and for producing electric light. Particularly is this the case in small towns and villages, which by the introduction of these facilities might find it possible to carry on many industries with greater advantage than at present. This would be a desideratum not to be despised, as it is now the object of statesmen, if possible, to prevent people from crowding into the larger towns, seeking the employment which to a considerable extent is dependent upon efficient machinery. As a body of men having at heart the physical welfare of the inhabitants of our towns, we should welcome the results foreshadowed here as a most desirable thing.

Some public authorities which are in the unfortunate

position of not owning the gas works, have frequent and reasonable cause for complaint with respect to both the efficiency and the price of the light supplied to the street lamps.

Where the conditions of the locality are favourable for the utilisation of water for driving dynamos for producing electric light, the public authority is possessed of a strong lever for the reduction of its gas bill, if it does not inaugurate electric lighting. A case in point occurred not long ago at Carlow. The municipal authorities quarrelled with the gas company and determined to discontinue gas lighting, and to start electric lighting instead. Carlow being situated at the junction of the rivers Barrow and Burren, plenty of water power was available. A disused corn-mill, five miles away from the town, was converted into a dynamo-room, the old waterwheel of the mill doing the necessary work. It is, however, intended to erect a turbine in the future. The wires conveying the current are carried overhead on poles to the town.

Efforts are being made in the Alpine countries to use the masses of water which rush wildly down the mountain sides as a means of producing electricity. Turbines placed at the foot of the falls are turned by the force of the water, and a dynamo is attached to the turbine and driven by belting. In this way no fewer than 12 towns in Switzerland are fixing up electrical apparatus for lighting and power purposes. In places where falling water abounds, electrical energy can be produced cheaply. As an illustration, it may be mentioned that an electrical company has been formed at the village of Faide, on the Gothard Railway, a place numbering 1,000 inhabitants. By means of iron pipe, a small supply of water is obtained from the neighbouring Pimmogna torrent, which drives below a small high pressure turbine, which in turn drives a dynamo supplying 360 glow lamps. The whole cost is under £2,000, which sum is divided into shares of £15, the owners forming the company. In this manner, in addition to the streets and railway station, the peasants and working-men have their houses supplied very cheaply with the electric light, which is elsewhere regarded as a luxury, but which Prof. Preece regards as a great sanitary agent.

When Mr. W. B. Bryan, C.E., was the borough engineer of Blackburn, he had to deal with the sewage of a district which had been newly incorporated by an extension of the borough boundaries, and lying 24ft. below the sewage outfall. He therefore designed a pumping station, the engines to be actuated by pressure from the town mains. The pressure in the mains was 125lb. to the square inch. The engines worked automatically, and were capable of raising 1,000,000 gallons in 24 hours 24ft. high. Mr. Baldwin Latham in a number of cases has been using high-pressure water for transmitting power for automatically pumping sewage. At Friern Barnet, for instance, he is transmitting power from the sewage works to a point a mile distant, and lifting the sewage of an isolated district 55ft. high into the gravitation sewers. Sewage is raised at Brentwood by means of a waterwheel. Small motors driven by sewage are used for working lime-mixers, etc.

In connection with power mains, a small jet of high-pressure water injected into a larger jet from the water works mains intensifies the pressure of the latter in the delivery hose, and also increases the quantity. A pressure of 40lb. to the square inch in a water main will throw the water issuing from a hose to the height of from 40ft. to 50ft.; but if water is turned on through a ⅜in. opening from the high-pressure main of 750lb., the water will rise to a height of from 90ft. to 100ft. through the atmosphere. Sir E. M. Shaw says this result would be very satisfactory, the pressure being as great as from a fire engine.

Another application of water power was made in the iron subway under the Thames just below Kingston Bridge. The subway was constructed of cast-iron plates bolted together in segments, forming rings 18in. deep, the diameter being 9ft. The method employed in driving the tunnel and fixing the plates was similar to that adopted in the construction of the City and South London Electric Railway. An iron shield of slightly larger diameter than the subway itself was forced forwards into the clay by powerful hydraulic jacks for a distance of about 18in., sufficient to insert one ring of the cast-iron plates. The Tower Bridge is provided with two steam pumping engines for hydraulic machinery, each 360 h.p., eight large hydraulic engines, six accumulators, and four hydraulic lifts in towers for passengers. The hydraulic forging presses at modern engineering works far exceed the Nasmyth hammer, which was once considered to give wonderful results. These presses are of 4,000 tons, and are worked by 2,000 h.p. pumping engines, and commanded by travelling cranes capable of lifting 150 tons. Altogether, hydraulic power is very serviceable in the working of ponderous machine tools, as it is also in the working of cranes, etc. We are indebted to water power in no small degree for the cleanly and noiseless lifts which are the comfort of lofty houses and flats.

No doubt the efficient utilisation of water power presents many difficulties which it is the duty and privilege of engineers to overcome. Surely there is a splendid field in many directions for the employment of such a well understood natural power as that of water.

SOCIETY OF ENGINEERS.

VISIT TO THE FERRY WORKS, THAMES DITTON.

On July 20th, a visit was paid by the members of this society to Messrs. Willans and Robinson's works. The Ferry Works, Thames Ditton, were started in the year 1881, for the construction of steam launches and yachts, and for the manufacture of the marine form of the Willans engine, as then made. Soon after the engine was modified for land work, and was applied extensively for electric lighting, and in 1885 the present pattern, well known as the "central-valve" engine, was produced.

In November, 1888, the works were almost completely destroyed by fire, and in the following year they were rebuilt on a greatly improved plan. They include at present a foundry, containing a 20-ton traveller, driven electrically, and two cupolas, with fans driven by electric motors.

Close to the foundry is the machine shop (about 140ft. by 120ft.), a one-storeyed building, with a gallery along the west side. It has a weaving-shed roof, the light coming from the north, and is divided into six similar bays, with interchangeable overhead travellers. At present, one bay is used as a store for manufactured parts, and one corner of the building is also used as the experimental and testing department, but a new building is to be erected for this purpose in the space between the present machine and erecting shops. The present testing department boiler is capable of supplying steam for about 200 i.h.p. or 250 i.h.p. up to 200lb. pressure, but two other boilers of equal capacity have been ordered, as well as a water-tube boiler for exceptional pressures, so that when the new testing arrangements are complete the largest engines at present made by the company—of about 700 i.h.p.—will be able to be tested to full power under steam before going away. Brake apparatus equal to at least this horse-power will also be provided.

The erecting shop, measuring 100ft. by 60ft., is commanded by an electrical overhead traveller, capable of lifting 25 tons, and, like the machine shop, has a weaving-shed roof, with north light; adjoining this is a building containing the pattern shop (the machinery in which is driven by an electric motor), pattern stores, and a mess-room.

A complete system of gauging is in operation, and all parts of the engines are standardised, and are as far as possible kept in store.

A rigid system of inspection of work prevails, both after each operation, and when the parts are finally passed into store. The inspectors are furnished with minute instructions as to the allowable deviations from standard dimensions, and are held responsible for any errors which may pass them. All work is passed through the stores on completion, and not directly to the erecting shop. There is a very complete apparatus for standardising electrical instruments, and the appliances for steam engine testing are probably inferior to none in existence.

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

TRAMWAY WORK.

The paper of Mr. Cox read before the Municipal Engineers, and given in our issue of last week, has created a considerable amount of interest. The county borough of Bradford has done much to solve the problem whether it is best for the local authority to carry out its own lighting or be dependent upon a supply company. Our contention, which has not been ineffectively advocated, is that the municipal authorities should carry out their own lighting; if this course is impossible, the next best thing is to form a local company, and only as a last resource should an outside company be permitted to do the work. Naturally, the local company will in many cases have to be promoted by outsiders. Bradford took the best course, and carried out the experiment of supplying current. The weak points of central station work soon made themselves known to men accustomed to make money by the use of machinery, and they looked around for means to get a fuller load on during a longer period of the day. It so happened that some new tramway work was projected, and it was thought that electrical energy would be just the thing to use. The use of electricity would kill two birds; it would put a more constant load on the station, and would get rid of the objectionable steam traction. Hence the authorities determined upon an experiment that should give them data to consider the application of electricity for the whole traction on the projected line. The results of the experiment and the conclusion of the borough engineer are set forth in his paper. We have, however, to notice that he has—and we think, from his point of view, justly so—put the worst construction upon the experiments, so that if the Council determine to continue with electricity they may know the very worst that may happen. Still, it would be very safe to prophesy that from the figures given deductions of a vastly more favourable character as regards expense can be made, and it is tolerably certain would be nearer the true result when the annual balance-sheet of a year's normal working was made out. Thus Mr. Cox's estimates are worked out on a 2½d. basis per B.T.U., while he admits that the current could be supplied at 2d. per B.T.U., that an independent firm have offered to supply at this lower price. This means of course that the central station would and could supply at the lower price. Then again in the discussion, Mr. Cox himself—and others—drew particular attention to the low annual mileage of 80,000 miles. Many of the items in the estimate would be reduced with a large mileage. The estimate of the engineers—Messrs. Easton and Anderson—although also based upon 80,000 car miles, comes to only 8·324 pence. In this latter estimate current is taken at 2d. per B.T.U., which results in 2·784 pence per car mile, as compared with 3·920 pence of Mr. Cox. There is another point to which attention might be called. In an experiment the engineers would naturally be on the safe side as regarded the power, but when continuous running was the order, economy, always keeping in view efficiency, in every direction would be sought; hence, minor alterations in mechanical details as warranted by experience

would almost certainly further reduce the cost of current per car mile. It seems also that a saving ought to be made in the equipment of such lines. We know of at least one 'bus company that has twenty-five cars running to one idle. Mr. Cox estimates four cars running with three idle, that means between 40 or 50 per cent. of rolling-stock idle. Would not the proportion of one idle to three running be sufficient for every purpose? These are just some of the criticisms which Mr. Cox's paper demands, for it must never be forgotten that the duty of the borough engineer is to guard his council, and hence to exert the utmost caution in preparing reports and estimates. It is better for him to pluckily err on the safe side than to cut matters so closely that little margin for eventualities is allowed. We trust, in considering Mr. Cox's report, the Bradford Corporation will also give due consideration to the views we have advanced and to others of a similar character. The estimated return for the Wakefield-road line is much less than is obtained on some other of the Bradford lines, and it is to be remembered that almost without exception the introduction of electric traction upon tram lines has been followed by an increase per car mile in the receipts.

CLAYBURY TENDERS.

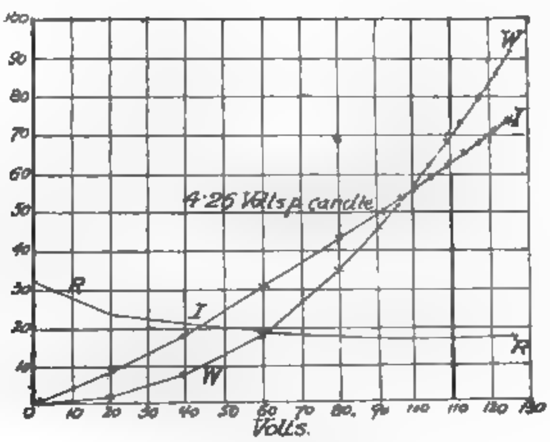
On Wednesday the *Contract Journal*, which, as most of our business readers know, makes a speciality of giving results of tenders, gave the list of those received by the London County Council for the electric lighting of Claybury Asylum. The list is a startling compilation, because it knocks the bottom completely out of all preconceived notions as to the knowledge electrical firms have of tendering. The lowest tender was to the amount of £13,970, the highest £28,400 — a difference of £14,430, or some £460 more than the total amount of the lowest tender. It is difficult to understand this, especially as in this case contractors were not left to their own sweet devices, but tendered upon the same specification. As one contractor remarked, "Our tender could well have been £3,000 or £4,000 lower had we been able to modify the specification in a way that would really have made the work better." There is no wide divergence between successive tenders; it is only when we come to a summation of a large number of tenders that the amount becomes startling.

THE NEW TELEPHONE COMPANY.

The prospectus of the New Company is before us, and, as might have been expected by the references made at the meeting of the National Company the other day, shows a compromise has been effected, and that amicable arrangement is to take the place of fierce competition. It was clear to all who had studied the subject that one or other company would have to take a back seat, and perhaps the best result that could have happened is the combination. By it the National practically admits its service to have been far from perfect, and that the New has something better to propose. The National takes all the shares that the rules of the Stock Exchange allow, nominates one-half the Board, and still retains control of the telephonic interest for the country. If recent agitation leads to a cheap and efficient service, the needs of the public will be served, for it is hardly in the nature of a prophecy to foreshadow the total amalgamation of the two concerns before many years are over, unless some wise Government plucks up courage to take over the work. So far as London is concerned, we may look for a gradual development of the twin-wire system till the whole system is complete, and no subscribers are left in any other direction. The decreased rate of subscription should bring additional thousands on the exchanges, and it is only when every house has its telephone that the full benefit of this modern invention will be understood. It is difficult to know whether to congratulate the National or the New upon the result, but at any rate the former has shown its wisdom in falling into line, while the latter has secured an easier task for providing a system which all competent persons allow is far preferable to that we have been accustomed to in this country.

VARIATION OF VOLTAGE AND EFFICIENCY OF LAMPS.

The influence of the variations of voltage upon the efficiency of incandescent lamps is a subject which specially appeals to supply companies' managers and engineers. M. G. P. Roux, of Paris, has communicated to us, as below, the results of a series of tests which he has recently carried out to determine the consumption in incandescent lamps under different voltages. These tests were made with an Edison-Swan lamp of 16 c.p., 110 volts, with a normal consumption of 4 26 watts per candle-power.



CURVES OF EXPERIMENTS ON INCANDESCENT LAMPS.

Energy 4·26 volts at the thick line (110 volts). Resistance, R, cold at start (by bridge) 321 ohms. Resistance, R, at finish 172 ohms (calculated).
I = $\frac{1}{100}$ths of ampere. W = watts. R = 10 ohms.

In the first set of tests, the results of which are given in Table I., and in the curves of the diagram, it is shown that the resistance of the lamp diminishes as the pressure increases, which means that the watts absorbed increase more rapidly than the *square of the voltage*, and that an increase of 2·24 per cent. of watts must be reckoned, for an increase of 1 per cent. in the volts—in other words, an increase of 3 volts on an ordinary circuit—means an increase of about 7 per cent. of electrical energy absorbed.

The tests were commenced at 20 volts and carried to 126 volts. The figures in the first and second columns of Table I. were taken with a Deprez-D'Arsonval galvano-

meter standardised with a Post Office standard battery, 1·07 volts, and a Fery standard cell.

Table II. shows the percentage of increase of consumption of energy in the lamp for variations of voltage within the ordinary limits. The mean is 2·24 per cent. for 1 per cent. of variation of voltage.

TABLE I.—TEST OF AN EDISON SWAN LAMP, 16 C.P., 110 VOLTS.

Volts. E.	Amperes. I.	Ohms. $R = \frac{E}{I}$.	Watts. W=E I.
0	0	321*	0
20·3	0·085	239	1·725

			Mean.. ...	2·24
109·5 to 121·5. .	11·2	67·9 to 85·6 .	26·2	2·36

It is certain that the lighting power is increased at the same time as the voltage, but not in the same proportion, and there remains here a defect which the constant progress in the manufacture of incandescent lamps will certainly cause to disappear, so that the consumer could be charged not by consumption of energy in his lamp, but rather by the amount of light supplied.

ELECTRIC CONDUIT ROAD IN CHICAGO.

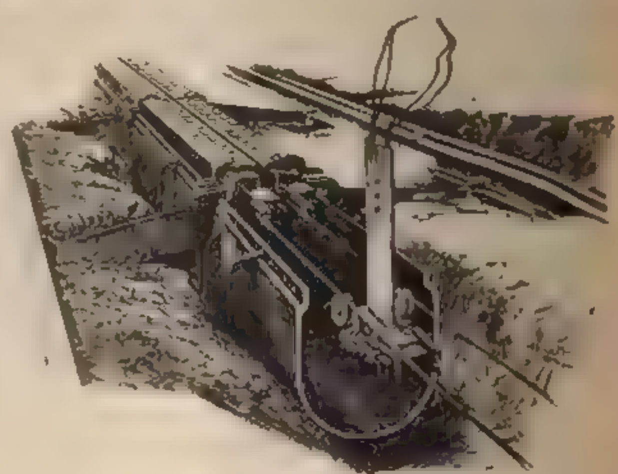
While the hot battle for and against the overhead trolley has been going on between the street car companies and the municipal authorities in various cities, resulting in New York and Chicago in the adoption of the cable, a street car company in the latter city has been experimenting quietly with a conduit electric road in order to satisfy itself on the question of the possibility of working such a road successfully. This road has now been running a number of months, and from all reports appears to have given complete satisfaction; a short description of it may therefore be of interest.

The conduit used is that known as the Love system, already mentioned and illustrated in our issue of July 4, 1891. It has since been changed slightly in details and improved in accordance with requirements which its introduction into practice have shown to be necessary. Much of its present success is due to the earnest efforts of the general manager, Mr. Albert G. Wheeler.

The accompanying illustration explains itself and needs little comment. One of the important features is that the top cover of the conduit consists of rolled steel strips or angle irons, having a deep vertical flange on the side bounding the slot. These angle irons are laid in long lengths, being secured in place by the clamps shown, by releasing these fastenings, which is a very simple matter, the angle-irons are readily removed, which open the conduit and renders it easily accessible for examining and repairing the wires, cleaning the conduits, and other purposes. This appears to be a very important feature, as one of the difficulties with a conduit is usually its inaccessibility, unless made large enough to admit a man, in which case it becomes expensive. It is stated that it requires but a few men and a very short time to open long lengths of the conduit.

The flange on the slot side extends lower down than the wires, and therefore protects them in a measure from interference on the part of the meddlesome small boy, who in other systems delighted in poking wires into the slot and seeing the sparks fly. It will be noticed, too, that both lead and return are insulated, which overcomes a number of difficulties experienced on grounded railroad circuits, and too well known to be enumerated here. The overcoming of these difficulties is by no means a matter of small importance.

Another feature is the means of support and insulation of the trolley wires, as shown in the cut. Great difficulties were at first experienced in the insulated support, but they claim that the present form overcomes all this, and that it is perfectly satisfactory, the wires being well insulated even in very wet weather, and when the streets are flooded with water. As will be seen, this arrangement takes care of the expansion and contraction of the wires. The rest of the conduit construction, with the rail supports, roadbed and rails, are said to be the same as those of the best cable roads.



The Love Electric Conduit.

One of the parts which was very troublesome at first was the trolley itself, but now they state that they have overcome this also, and that the very simple form of trolley shown, which is the one used now, is perfectly satisfactory. The trolley wheels are slightly smaller than those used on overhead roads and are loosely supported so as to admit of a small amount of play in all directions, just enough to adapt themselves to the inevitable slight irregularities, chiefly at curves. The whole trolley bar is easily detached and replaced if broken.

The conduit is well drained by means of frequent pipe connections to the sewers and settling-boxes. In order to clean it of mud and other sediment, a brush is attached to the trolley, which sweeps the dirt into receiving-boxes.

The road is 1⅝ miles long, embracing four curves of 35, 45, and 55 degrees radius, two double and two single track crossings and 10 switches. It was built during the past winter on the tracks of the North Chicago Street Railway Company.

That the road has been running quite successfully is best shown by the fact that the North Chicago Street Railway Company has accepted the road. In a letter from President Yerkes, of that company, he says: "So far as the system itself is concerned it gives us perfect satisfaction, and contrary to my fears the insulation is not interfered with in any manner by moisture. We have had some of the most severe rains in this vicinity during the past three or four months that I have ever experienced, so much so that at one time the cars ran through water on the track 3in. or 4in. deep, the trolley in the conduit running in the water owing to the inability of the sewer connections to carry off the flood fast enough, but at no time was the road stopped from this cause." After referring to some unfavourable

same voltage. Each of these armatures had been recently repaired, and although they had been well baked there may have been some leakage through the green shellac. The Foucault current in the cores were probably greater than in the new armatures. With the same armature and fields

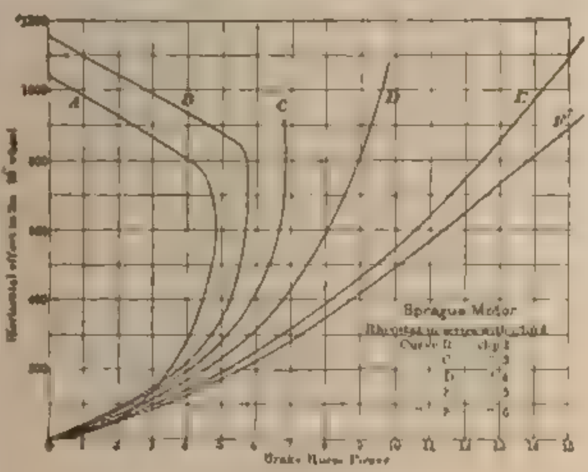


FIG. 5.

the efficiency is a few per cent. higher cold than when hot. It has been the aim to run as nearly as possible at the temperature of ordinary running, so that the fields were comfortably warm but not hot. It is confidently believed that the efficiency of these machines would be considerably above 90 per cent. if taken at armature shaft and with full voltage.

heavy. On starting the car the current is very heavy and the field is saturated with a small number of turns, hence the torque with a given current is nearly the same, whatever the windings of the field. The speed and counter E.M.F. are small at starting; hence the potential difference at the armature brushes should be reduced until it passes only enough current to start the car without jerking. The easiest way of reducing the potential difference at the brushes is by interposing resistance; and the heat developed by the C^2R can be cared for more easily and cheaply in an open rheostat than in the field coils. Rheostats of iron and mica are cheaper and more heat-proof than cotton-covered wires. This forces the conclusion that for the heavy load due to accelerating the car at starting, the field should have the smaller number of turns, and as the car reaches normal speed, and the horse-power and C becomes less, the efficiency of the motor would be raised by increasing the number of turns in the field. This conclusion is exactly the reverse of the common practice of manufacturers who sacrifice some efficiency for speed at small horse power. It is also in line with the experience of the road mentioned, that replaced the commutated fields with a single series coils of No. 7 wire, and later with No. 5 wire. This heat loss could be saved, and the average efficiency raised by using the two motors in series at the start, and afterward cutting out one or putting the two motors in parallel if necessary, as the speed increases and horse power decreases. An average of 12 tests on the road shows that with two motors on a car it requires 27 per cent. less current if only one is working.

In Fig. 3, Curve A shows the efficiency of Sprague motor with single pair of coils when the whole of a Thomson-Houston rheostat is in circuit. B shows about three-fifths

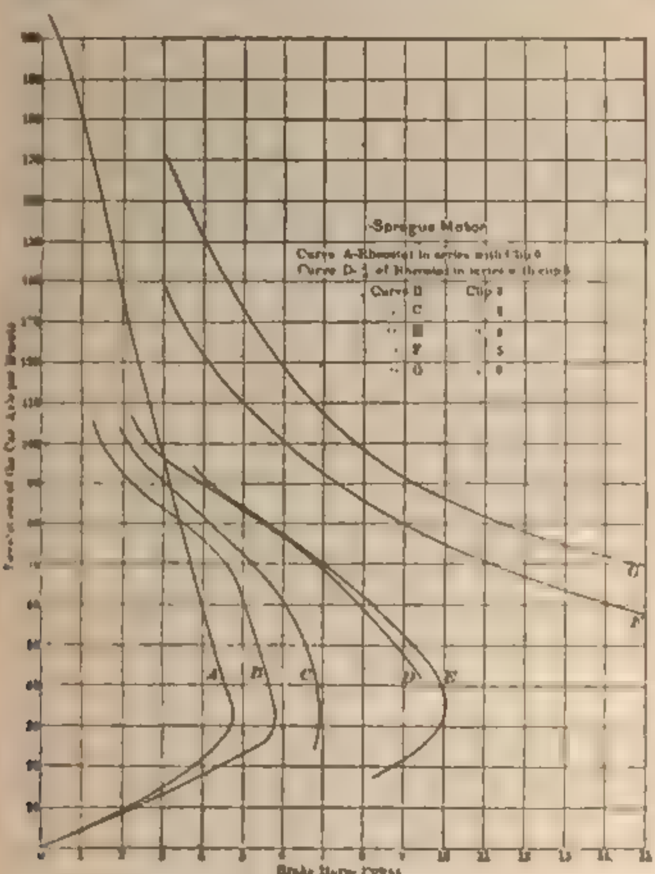

FIG. 6.

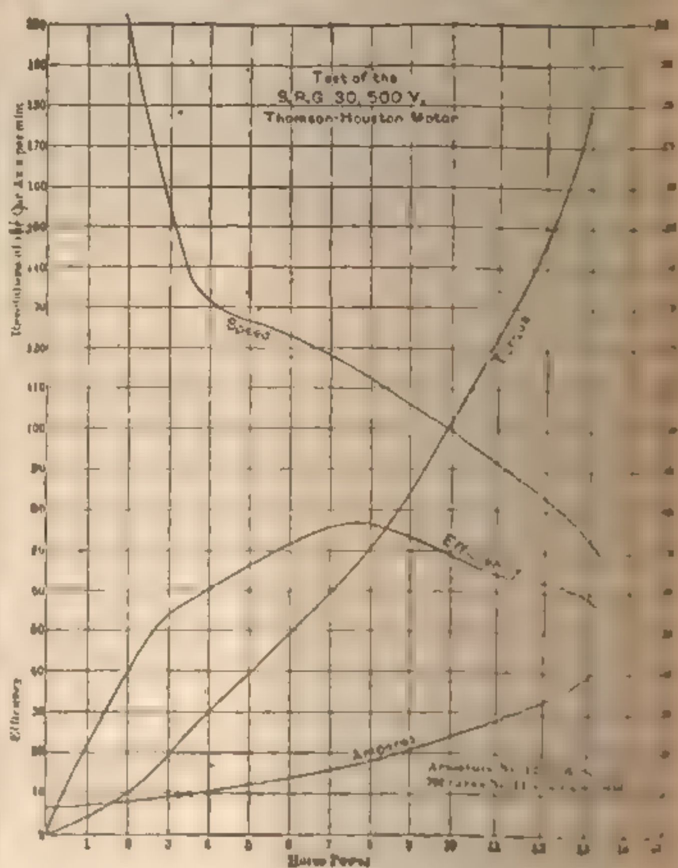

FIG. 7.

Fig. 1 shows efficiency curves for the motor, with different combinations of the field coils.

In Fig. 3, Curves A and B show efficiency of the machine with 857 and 611 turns of No. 7 wire in the field coils. It will be noted in Figs. 1 and 3 that the motor has highest efficiency with the larger number of turns on field coils until the iron is saturated, when the better efficiency is given with smaller number of turns and consequent lower resistance in field. This shows the advantage of working on the fifth and seventh clips with barrel regulator, or of cutting out part of the turns on field when the load is

of the rheostat in use; and in C it is all out. The dotted line, A^2, gives the efficiency as calculated from the difference of potential about the motor alone. Curve A, is not strictly comparable with the others on account of the necessary variations in the voltage at the motor, but it does show the increased efficiency to be obtained by utilising the superfluous voltage in a second motor in series. In this connection it is interesting to note that the resistance of rheostat, as calculated from current and potential difference, decreases with increase of current. This is to be expected, since the larger part of the resistance is due to

surface contact between the plates of iron in the rheostat, these being pressed together more closely as the iron heats. A similar effect, but much more marked, has been noticed in earlier experiments by one of us, with alternate plates of carbon and iron.

Figs. 4, 5, and 6 show curves of torque, speed, and horse-power, referring to the No. 6 Sprague motor. In Fig. 5, A shows horse-power and horizontal effort on a 30in. wheel; B, C, D, E, and F clips 2, 3, 4, 5, and 7, respectively. In Fig. 6 A shows speed and horse-power, with all of the rheostat in; E with ⅗ of rheostat in; B, C, D, F, and G clips 2, 3, 4, 5, and 7, respectively. These may be compared with results presented by Prof. S. H. Short before the Chicago Electric Club, March 28, 1892. Fig. 7 gives curves of current, torque, speed, and efficiency from a 15-h.p. Thomson-Houston single-reduction motor. The reduction ratio is 4·7857.

(To be continued.)

ELECTRIC SWING.

Mr. Volk, of the Brighton Electric Railway, has devised an electric attachment for swings. The direct pull of a solenoid is utilised, the core of the solenoid being connected with a wire cord, which passes over a pulley, then horizontally to the side arms of the swing.

The make and break action is rather peculiar, as with the reversal of the motion of the swing the contact is made and broken independently of the angular motion of the swing. This is effected by means of the wire cord running through a gripper attached to the contact lever, so that the cord slips freely through the gripper after carrying the lever to either extreme of its motion. The current is about three-quarter amperes at 160 volts. The motion is said to be peculiarly smooth and pleasant.

ELECTRIC CLOCKS.

The merits of the self-regulating electric clocks recently exhibited at the Crystal Palace Exhibition by Messrs. Shippey Bros. are beginning to make themselves known, for we learn that this firm are busy fitting up sets of these ingenious clocks in country mansions, also in several engineering works and public buildings in various parts of the United Kingdom. During the past month, amongst others, they have carried out private installations for Mr. Gilbert Harrison, "Manx View," Carnforth; Captain Bilton, Norfolk-square, Brighton; Mr. L. M. Barron, Slough; Mr. Valentine Holmes, Frithville-gardens, W.; Mr. Henry Bevan, South Woodford; Messrs. Amos and Smith, where clocks are under test at the Victoria Docks, Hull; the offices of Messrs. J. H. Burt and Co., Cannon-street, and numerous other public buildings and mines in England and Wales.

The principle of these clocks is simple; for instance, in the hall of a private residence, or in the chief offices of works, a standard electric regulator is placed. This regulator works by its own action for, say, 59½ seconds, when electric contact is made and a magnetic pull is exerted, and during the remaining half-second required to complete the round of the minute wheel an ingenious contact arrangement lifts a small ball and momentarily breaks the circuit, so that the wheel becomes free again. Then by the aid and momentum of the pendulum the motion is continued, and the automatic electric action goes on perpetually day after day, year after year, for one, three, or five years, according to the battery power supplied.

The regulators, which are made in three sizes according to requirements, are capable of regulating sets of either 10, 20, or 30 secondary clocks connected in series, and these can, of course, be fitted in various parts of the house, buildings, works, or railway stations, as the case may be, and thus can be successfully driven by four to six volts of intermittent current within a radius of two or three miles. The secondary clocks, being in sympathetic action with the main circuit clock, are electrically regulated every minute, and it is claimed as part of the invention that by this method no clock can deviate from each other for more than one second under any conditions whatever. The system, which is covered by several patents in all countries, is the invention of Mr. E. Schweizer, and as an illustration of the success of the system when worked on a large scale, it may be mentioned that the municipality of Vienna has had working for some time past over 600 of these clocks, regulated from four main centres; standard time is thus assured in all parts of that city. A special type of clock is also manufactured and supplied for fixing up in central electric stations, which is guaranteed to be no way affected by the vibration of the machinery or magnetism of the electric plant. The progress of this new system of horology bids fair to make it one of the important inventions of the age, and it will be watched with interest by all firms or authorities seeking to secure a reliable clock which will without trouble give uniform correct standard time.

ON THE APPLICATIONS OF ELECTRICITY IN THE ROYAL DOCKYARDS AND NAVY.*

BY HENRY E. DEADMAN, CHIEF CONSTRUCTOR, PORTSMOUTH DOCKYARD.

This is an age of electricity; and the fact is well exemplified on board a modern battle-ship of the Royal Navy. Some of the applications of electricity in the naval service do not come within the scope of ordinary mercantile practice; and in the case of those which do, the naval experience is of a special kind, and may be of some value to those outside the service. A statement therefore of naval methods and practice up to date may not be without interest and instruction to the members of this institution. At the present time visitors to Portsmouth Dockyard will probably be surprised, if not disappointed, at the somewhat primitive character of the workshops devoted to the electrical testing and construction. This branch of work was commenced in a very small way about 17 years ago, and found a temporary home in a small shed which had been previously used for a different purpose. As the work from time to time has grown, this shed has been enlarged as far as available space would permit. Designs have been prepared for a more substantial and suitable building, in the hope that in time the Admiralty will be able to devote sufficient money to providing a proper habitation for this important branch of dockyard work.

The larger proportion of the plant required for electric installations in the navy is not made in the dockyard. Formerly all dynamos and their engines were obtained entirely by contract; but recently five sets of these have been designed and constructed in the dockyard. After patterns of the smaller fittings have been fixed, the supply of these also in bulk has generally been obtained by contract. There is, however, a great deal of work left to be done in the dockyard, in testing and installing these fittings in the ships, in carrying out repairs, and in devising and preparing patterns of new fittings to meet the constantly growing requirements of the navy. There is also some work which for obvious reasons is confined to the Royal workshops.

The applications of electricity in the navy may be dealt with under the following heads: (1) Search-lights; (2) internal lighting of ships, including temporary installations in ships building and repairing; (3) torpedo and gun circuits; (4) electric communication; (5) other applications.

1. Search-lights.

The introduction of the search-light—without which no modern warship or torpedo-boat would be considered complete—dates from 1876; and the first vessel in the navy fitted with a search-light apparatus was the "Minotaur." Some experiments had been carried out in the previous year by Messrs. Wilde and Co., of Manchester, on board the gunboat "Comet"; and these proved so far satisfactory that a complete plant was ordered and fitted on board the "Minotaur." The dynamo employed was one of the alternating-current type with 32 magnets, and it was driven at about 400 revolutions by a belt from an auxiliary pumping engine. The projector was of a primitive type, and pedestals were fixed in three different places, from any one of which the same projector could be used. It was fitted with a parabolic reflector and with dioptric and diverging lenses. A diaphragm was also provided for enabling flashing signals to be made. The lamp employed was Wilde's, and was a vertical one. The carbon rods were square in section, and their holders were made to slide on two pillars, and were moved up and down by a central pillar with a screw thread cut in it. The lamp was hand-regulated, and one lead was put to earth. The "Téméraire" in the same year was next fitted in a similar manner, with the exception that a Mangin projector was introduced, fitted with Wilde's lamp, lens, etc. In the next year, 1877, the "Dreadnought," "Neptune," and several other vessels were fitted with the same class of apparatus.

In 1878 direct driving was first introduced. In this year Messrs. Wilde and Co. coupled their machines to engines made by Brotherhood and by Chadwick, of Manchester. The dynamo was also improved, so as to be able to maintain two arc search-lights at one time. In the same year also the "Triumph" was fitted by Messrs. Siemens Bros. with a search-light installation. The dynamos were four in number, of horizontal type, arranged in two pairs, and each connected in parallel to one circuit. A switchboard was fitted, for enabling any two of these dynamos to be coupled up together on any circuit. It consisted of a wood base with two sets of bars at right angles to each other, one set on the top of the base, and the other underneath. One set of bars was connected to the dynamos, and the other to the circuits. At their intersections these bars could be connected as required by means of suitable plugs. The projector used was a Siemens holophote, which was heavy and clumsy, being made largely of cast iron. It was fitted with diverging and dioptric lenses. Of these, the latter was com-

* Paper read at a meeting of the Institution of Mechanical Engineers.

posed of concentric glass rings of triangular section, held in a metal frame. It had also a flashing arrangement. The lamp used was one of the Siemens self-regulating type, and had a small mirror fixed to it. It was complicated, and frequently got out of order. The carbons were apt to stick together, and the lamp was sensitive to any slight variation in speed of dynamos. This lamp did not come into general use.

Subsequently, the Gramme dynamo was introduced for search-lighting by Messrs. Sautter Lemonnier, of Paris, and in 1881 the "Inflexible" was fitted with this dynamo. In this installation the Mangin projector was used, with a Mangin mirror instead of the dioptric lens. The lamp was hand-regulated and inclined. The Gramme dynamo has since been superseded by others of later make, but the Mangin mirror and the inclined hand lamp survived, and became the standard service fitting.

Naval Service Projector.—Out of these earlier attempts the modern naval service projector has gradually been evolved, which has now become familiar to most persons. It consists of a cylindrical lantern made of very thin steel, with a silvered glass parabolic mirror at the back end, in the focus of which an arc light is produced between two carbon sticks, held in what is known as an inclined hand lamp, the carbons standing at an angle of about 70deg. to the axis of the mirror. The feeding of the carbons is not automatic, but is accomplished by hand; and the lantern is so suspended that it has motion on its pedestal through the whole circle in azimuth and through about 60deg. in altitude. During its motion the electrical connections are kept up by suitable rubbing contacts. A switch is fitted in the pedestal for switching the current on and off. The circuit wires, main and return, are brought from the main switchboard to the switch on the pedestal, thence to the rubbing contacts, and finally pass close together up one of the hollow arms of the lantern support, and through the trunnion-bearing to two springs at the bottom of the lamp box. The lamp when put in makes contact with these springs, and completes the circuit through the carbons. Two sizes of these projectors are used in the naval service, a larger with a 24in. mirror for ships, and a smaller with a 20in. mirror for torpedo boats. The parabolic mirror in these projectors converges the rays into a powerful and penetrating cylindrical beam of light. At the front end of the lantern, diverging lenses can be attached, for spreading the beam over a larger surface when desired; or a flashing screen can be affixed for signalling purposes. The two most important parts of these projectors for the production of a good and steady beam are, of course, the reflecting mirror and the carbons. For the supply of these articles the naval service was until recently dependent entirely upon French manufacturing firms. The Admiralty, fully alive to the dilemma in which this country might, under certain circumstances, be placed, have sought to induce English manufacturers to enter into competition with the French firms for the supply of these articles; and every thing of this kind which has been offered with the slightest promise of success has been fully and carefully tested at Portsmouth. The English manufacturers have no doubt had no easy task to accomplish; for, disregarding cost, the French mirrors and carbons left nothing to be desired, and are still the standard to which all others are referred.

Mirrors.—As regards mirrors, the qualities required are three: first, that they shall project a cylindrical, sharply defined, and homogeneous beam of light of great intensity and penetrative power; second, that when in operation they shall not be liable to crack by contact with water, in the form either of rain or of sea-water spray, or by a blast of cold air; third, that they shall resist the concussion caused by the discharge of heavy guns. These qualities should be combined at a moderate cost if possible, although efficiency is the primary consideration. Thus far mirrors have been submitted for trial by six different English makers, and by others specimens are being prepared for future trial. From among these at least one successful English specimen has been obtained, which compares in all points favourably with the French production; and one half of the supply for the navy will this year be ordered from the firm producing this specimen.

Carbons.—With regard to English carbons, the results were for a long time disheartening, even after several attempts by the same firm, none of the specimens submitted for test approached in efficiency those of French make. The three qualities required in good carbons are that they shall maintain a steady arc without flaming or excessive hissing; that they shall be perfectly pure and homogeneous in structure, and shall preserve a well formed crater on the positive carbon and a well formed point on the negative; and that the waste shall be steady and uniform, without cracking or crumbling. A certain amount of success has already crowned the persevering efforts of English manufacturers. Although the English carbons are not even yet fully equal to those previously obtained from France, it is hoped they will soon come sufficiently near that standard to make them acceptable for use in the navy.

Projector Requirements.—The present service projector requires at least one man close to it, to direct the beam of light in any desired direction and also to feed and adjust the carbons as necessary. This is a disadvantage, because the position of a search light is evidently one affording a good mark for an enemy's fire, and is a bad position for observing the object illuminated, and it would be an advantage if the projector could be entirely manipulated from a protected position at some distance—for instance, from the ordinary conning tower. For this purpose two requisites are necessary: first, a good automatic lamp; and second, an efficient motor for giving the necessary movements to the projector. It is to these two improvements that attention is now being given. A good practical automatic lamp is the first necessity; without this a man must be stationed at the projector to feed the carbons, and being there he can also direct the beam of light. Several automatic lamps have been tested, but none have as yet been adopted for general use. One lamp, in which the carbons are regulated by a small electric motor in a shunt circuit, is promising, but, in its final form, it has not yet been returned from the makers. The field, however, is still open for invention in this direction. Experiments have also been made with an electric motor attached to the service projector, by which the movements of the latter can be directed and controlled from a distance. The results are highly satisfactory, but, as already stated, the invention is not likely to be brought largely into use until it can be combined with a satisfactory automatic lamp. Recently a wheeled carriage has been introduced for using a ship's projector on shore.

2. Incandescent or Glow Lamp Lighting.

Electricity is at the present day largely resorted to for the purpose of lighting internally the vessels of the navy; all the larger vessels, such as battle-ships and first and second-class cruisers, are now so lighted. Moreover, this mode of lighting is not restricted to the habitable portions of the ship, but is carried out to the complete exclusion of other modes, although the latter may be fitted as a reserve. Thus the electric lighting is extended to machinery spaces, coal bunkers, magazines, shell rooms, store rooms, gun quarters, etc., as well as to the illumination of compass cards, telegraph dials, bow and masthead and signal lanterns, semaphores, etc. Clusters of glow lamps beneath an enamelled metal reflector are also employed for lighting the upper deck when coaling or other operations are being carried on at night. In a large battle-ship like the "Royal Sovereign" there would be about 800 of these glow lamps, necessitating for this system alone some eight miles of electric leads, which are equivalent to something like 155 miles of copper wire of varying sizes, principally No. [illegible] legal standard wire gauge, or 0·036in. diameter.

Progress.—The first installation of internal lighting in the navy was carried out on board the "Inflexible" in 1881 by the Anglo-American Brush Company. It was a combined system of arc and glow lamps. The dynamos used were of the Brush type, of which the first specimen brought to this country was purchased by the Admiralty, and is still in use in Portsmouth Dockyard. Each machine was capable of maintaining 16 Brush arc lamps of 2,000 c.p. each. The lamps had double sets of carbons, each pair burning eight hours. These arc lamps were turned on and off by a switch opening and closing a shunt circuit of low resistance. With this plan it is evident a lamp could not be handled while the current was on, even if the light was turned off, because the lamp itself still formed a part of the circuit. A switch was accordingly devised in the dockyard by means of which the lamp could be cut completely out of the circuit. The glow lamps were fitted in sets of 18 in series, each set being placed in parallel between the main circuits of the arc lamps. Each glow lamp was fitted with an automatic cut-out, bringing into the circuit a resistance equal to about that of the lamp, in case the latter failed. This system now no longer exists in the "Inflexible," an installation on modern methods having been substituted for it. The five Indian troopships were next fitted throughout with glow lamps by the Edison Company, who used the Edison Hopkinson type of dynamo, giving a current of 180 amperes at [illegible]. The "Polyphemus" was also entirely fitted by Messrs. Siemens, and the "Colossus" by the Brush Company, the dynamos in the latter being of the Victoria Brush type. The "Polyphemus" was the only ship in the navy fitted on the single wire system. Afterwards, the adoption of internal lighting became general; all new vessels, except the smaller cruisers, were fitted, as were also the previous vessels on the first opportunity of their coming in for repairs and refit. There are now in the navy about 300 vessels either fitted or being fitted with electric lighting for search lights or internal lighting, or both.

Difficulties.—The earlier installations, although quite satisfactory so far as the illuminating effect was concerned, were certainly not satisfactory in regard to the endurance of the plant; in fact, they were a constant source of trouble, both the dynamos and the leads requiring frequent repairs or renewals. These troubles arose partly from faulty construction, and partly from the conditions necessarily existing on board ships of war, such as the necessity for placing the dynamos well down in the ship and under protection from shot; which relegated them either to the engine room with its high temperature and moist atmosphere, or to some other confined and ill ventilated spot. Under these conditions the insulation soon suffered, and the machine quickly got out of action. The leads throughout the ship suffered from the access of salt water, which caused much trouble by destroying the insulation, and producing short circuiting, thereby frequently setting on fire the wood casing in which the leads were run, or any other inflammable material in the neighbourhood.

Remedies.—Nearly all these difficulties have in the course of time been surmounted. While it is still necessary to place dynamos under protection for use in action, it has now become the practice to fit an additional dynamo capable of running all the lights generally required at one time, and to place it with its motor in an open space between decks, or on the upper deck, suitably sheltered. This is known as the peace or daylight dynamo. The introduction of lead coated wires marked an epoch in shiplighting; and these wires are entirely used in all the new installations, and are taking the place of the old leads as fast as the latter require renewal. These cables dispense entirely with the wood casings previously used, resulting in greater simplicity of fitting as well as increased efficiency. The wood casings are still used in America, even with the lead coated cables, but in the writer's opinion, while adding largely to the cost of the installation, they are likely to detract from its efficiency, as they form such convenient receptacles for water to lodge in.

Dynamos.—The Admiralty have not adhered to any one particular kind of dynamo, for although those of the Siemens type predominate in the navy at present, nearly all the well known makers are represented—such as Latimer Clark, Muirhead, and Co., the Electric Construction Corporation, the Silvertown India-rubber Company, Goolden and Co., Crompton and Co., and Parsons and Co. The experience gained in the testing and use of these machines of different types was of immense benefit in enabling those points to be discovered in which dynamos are most likely to fail, and in suggesting the direction which improvements should take. The weak points in most of the machines supplied were imperfect insulation, owing to want of sufficient care in building, and the excessive internal heating of the armature. In some cases the section of copper used was too small, resulting in the heating of the dynamo and the rapid destruction of the insulation. By direction of the Admiralty a design was prepared by Mr. Lane, electrician of Portsmouth Dockyard, for a machine to give an output of 400 amperes at 80 volts, which should embody the experience already gained, and should be free from the faults previously mentioned. Five machines have been built from this design, two of them for the "Rupert," a vessel now under reconstruction No opportunity has yet occurred for testing them under the conditions of sea service, but two have been used for about a year under full load, as temporary lighting plants for ships building, etc. At times, too, they have been worked for long periods above full load, from 420 to 430 amperes; and they have always given perfect satisfaction. They are driven at about 330 revolutions a minute by open vertical compound engines of 56 i.h.p., designed and constructed in the chief engineer's department of the dockyard. The total weight of the dynamo and engine with bed-plate is about 5¼ tons.

Other Fittings.—As regards the other fittings required to complete a successful installation—such as switches, fusible cut-outs, lampholders, shades and their holders, etc.—patterns have been adopted or devised in accordance with accumulated experience, to meet the special requirements of the navy; those are simplicity, combined with strength to withstand the rough usage necessarily experienced on board a fighting ship. The guiding principle in the present installations is to make every part of the circuit inaccessible to water by employing lead-coated cables, and by enclosing in metallic water-tight boxes all the principal switches and cut outs, and by effecting in all cases in the interior of water-tight distributing-boxes the subdivision of the mains, which themselves pass into the boxes and their subdivisions out of the boxes through water-tight stuffing-glands.

Switchboard.—With several dynamos and a combined installation of incandescent and search-lighting, a good switchboard is a necessity. The one generally used in the navy at present is susceptible of improvement; and a new switchboard has just been designed and made by Mr. Lane, the dockyard electrician, which promises to fulfil all the requirements.

Temporary Installations.—The employment of temporary installations of electric lighting in ships building and repairing has been a marked feature of recent practice in Portsmouth Dockyard. Probably more has been done here in this respect than has been attempted in any other Royal dockyard or private shipbuilding yard in the country, although these are now finding it to their advantage to follow the lead. So highly satisfactory have been the results of the experiments in this direction, that, with the exception only of the smallest ships, the electric light is now installed as a matter of course on board every new vessel at an early stage of its construction, and also in all vessels where repairs of any magnitude are to be carried out. The character of these temporary installations varies with the circumstances of each case. Where vessels are building in the docks adjacent to the electric shop, it is, of course, more convenient and economical to supply the current from a dynamo in the shop itself, the leads being carried to the ship on temporary wooden poles put up for the purpose. Vessels building on the slips, which are too far from the electric shop to convey the current to them in an economical manner, are served by a dynamo and motor placed at some convenient spot near the ship. After a vessel is launched, and generally for all vessels afloat, the most satisfactory method is to place a dynamo and engine with a steam boiler in the ship itself, generally in a temporary wooden house on the upper deck. By this means the light is maintained without interruption during the many movements of the vessel about the basins. The leads, lamps, etc., are fitted roughly. The cables are simply tied to clips fastened to the beams, etc. The switches are hung from the cables. The lamps with their holders are secured to wooden bases, and protected by wire guards without any globes.

Cost.—Although no exact comparison can be given between the cost of this mode of illumination and that of the old plan of lighting by candles, it is estimated that in a first-class cruiser like the "Royal Arthur" the total cost of the electric lighting during the whole period of building, including depreciation of plant, would be about £1,200. This would probably not much exceed, if at all, the cost of candles for the same period; but the vastly superior illumination obtained by the electric light—enabling work to be done better, more quickly, and under better supervision, to say nothing of the advantages in health and comfort to the workmen—would justify the continuance of this system, even though the actual cost should be much greater than that of lighting by candles. It is hardly an exaggeration to say that the excellent results as regards celerity and cheapness of construction which have lately been attained in Portsmouth Dockyard, could scarcely have been realised without the aid of the admirable illumination afforded by the system of incandescent lighting.

Testing of Dynamos.—Before acceptance from the makers all the dynamos purchased by the Admiralty are tested on receipt at a dockyard; and as no less than 150 have been tried at Portsmouth during the last two years, 1890 and 1891, the experience gained has been considerable. At the north end of the electric shop a space is fitted with cast-iron holding-down plates, of sufficient area to take several sets of plant at one time, and also with an overhead traveller for lifting. Steam at 100lb. per square inch, or other pressure required, is supplied by three boilers of locomotive type in the adjoining boiler-house. Adjacent to the holding-down bed is a separate enclosed room, containing all the various electrical testing instruments; and into this room the leads from the dynamos under test are taken. For enabling a dynamo on any part of the holding-down bed to be rapidly connected up with the instrument-room, two bare copper rods extending overhead the whole length of the bed are fixed to the roof trusses and insulated by slate. From these are suspended two hanging leads, the lower ends of which can be connected to the terminals of any dynamo under trial. The overhead bars are coupled to leads, which pass through resistances sufficient to give the full load, and then into the instrument-room. Nearly all the dynamos now purchased, except those for torpedo-boats, are of a capacity of 400 amperes at 80 volts, the latter being the Admiralty standard voltage for all dynamos and electrical fittings; and they are all direct-current and compound-wound. The dynamos are coupled direct to open vertical compound engines, working generally with 100lb. steam pressure at a speed of about 330 revolutions a minute. The dynamo and engine are required to stand first a continuous trial of six hours' duration with full load. Every half-hour the steam pressure, current, and E.M.F. are recorded, as are also the temperatures of the testing-room, field magnets, and armature. It is stipulated that one minute after the end of the trial the temperature of any accessible part of the machine must not exceed that of the testing-room by more than 30deg. F., and the maximum temperature of the armature at end of trial after stopping must not exceed that of the room by more than 70deg. F. If these limits are exceeded by more than 10deg. the machine is liable to rejection. These tests for temperature are considered to be of great importance, for if unsatisfactory the dynamo is not likely to remain long efficient The spare armature which is supplied with each machine is required to undergo a similar test for two hours. The current produced by any dynamo is measured by means of a Siemens ammeter; and as a check upon this the current can also be switched on to a Siemens dynamometer. There are several of these ammeters, and three dynamometers, of different sizes to suit the current to be measured. The leads pass through sliding resistance-boxes, so that the strength of the current can be varied as required for the compounding trials. The voltmeter leads taken from the dynamo terminals are also led into the instrument-room, and the E.M.F. is ascertained by means of three Evershed marine voltmeters. A switch is interposed, of such a nature that either any one or any two or all three of these voltmeters may be in the circuit, thus checking one another's accuracy. A Cardew voltmeter and also a Siemens voltmeter can be switched in, if desired. The Cardew voltmeter and the Siemens ammeter are the instruments actually used on board ships of the navy. Very delicate instruments, such as electro-dynamometers, are found not to be suitable for use under such circumstances. As additional tests the engines and dynamos are expected to stand without injury the sudden removal of the full load by the breaking of the circuit; and under such circumstances the maximum increase in revolutions or in voltage must not exceed 25 per cent. The dynamos are required also to be compounded so as to give a constant E.M.F. of 80 volts when the current is varied from 400 to 10 amperes, the speed being fairly constant during the time; and they are fairly tested to ascertain that these conditions are fulfilled.

Engines.—As regards the engines, great importance is attached to their economy in the consumption of steam. The makers are required to state the consumption of water per electrical horse-power per hour which they will guarantee shall not be exceeded. A fine is incurred for every pound of water per electrical horse-power per hour in excess of the maximum guaranteed; and if the excess amounts to more than 10lb. per hour, the machine is liable to rejection on this account. The water used is carefully measured, and every endeavour is made to avoid losses by leakage of steam, etc Importance is also rightly attached to the governing arrangements, and it is stipulated that the increase of speed when the load is gradually removed must not exceed 5 per cent.

Resistances.—Before the six hours' trial is started, and immediately after its conclusion, the resistances are observed of the dynamo complete, of the armature, and of the shunt and series windings of the field magnets; the resistances are thus obtained both when the circuits are cold and also when they are hot. For this purpose the leads from the terminals of the part whose resistance is required are taken into the testing room, and the resistances are obtained by a bridge made by the Silvertown Company, by a Thomson marine galvanometer, and by an ordinary scale, for which the light is given by an incandescent lamp behind. The ordinary Daniell cells are used, and a key is introduced, so that one, two, three, or four cells may be switched in at once without altering the leads. The dynamo and engine are further tried when fitted on board ship, and when the whole installation is complete.

3. Torpedo and Gun Circuits.

Torpedo Circuits.—When the Whitehead or fish torpedo was first adopted as an element in the offensive armament of ships of war, it was ejected from its carriage by means of an impulse-rod or piston actuated by compressed air. The ejection was effected by opening a communication valve between the impulse cylinder and a reservoir of compressed air. As it was necessary that the discharge of the

torpedo should be effected from an observing and directing station remote from the torpedo itself, electricity was early pressed into service for effecting the communication between the observer and the firing valve, and in 1879 an electrical arrangement was first fitted for enabling the firing valve to be opened from a distance. The method of ejecting torpedoes from a carriage by means of an impulse rod was soon abandoned, however, and the air gun principle took its place. By this method the torpedo is itself placed in a tube or gun, into which compressed air is admitted behind the torpedo, and the ejection is effected by the expansive force of the air acting directly upon the rear of the torpedo, exactly as the explosive force of gunpowder drives a shot out of a gun. When worked from a distant point the firing valve was still opened by electricity, but on an improved plan. In the earlier ships the batteries were placed below the water line, and the circuits were complete with main and return wires. Where not protected by armour or not below the water line, the wires were duplicated and kept apart from each other, as greater security against both circuits being destroyed at one time from the same cause. The circuits now used are earth circuits and are duplicated where exposed, as for instance near the torpedo tubes. The standing wires of the modern circuits are lead coated. The conductor is formed of a strand of seven wires of No. 22 legal standard wire gauge, or 0·028in. diameter. It is insulated with indiarubber, which again is covered with three servings of cotton tape prepared with india-rubber. The enclosing lead tube is covered with a strong tape saturated with a waterproof mixture. Where flexible leads are required they are formed of 36 wires, each of No. 30 legal standard wire gauge, or 0·012in. diameter, insulated, as before, with indiarubber and cotton tape and protected by a binding of hemp. The whole is saturated with Hooper's composition. Within the last few years powder impulse has been introduced for discharging torpedoes. For this purpose a cartridge containing a small charge of gunpowder is placed in a powder chamber prepared for it at the rear of the torpedo tube. The cartridge is fired by means of an electric current generated in a local circuit, that is, by a battery secured to the torpedo tube itself. This local circuit is momentarily completed by the action of the firing circuit from the observing station.

Gun Circuits.—Electricity is further employed in the navy for effecting the discharge of guns, either individually at the gun positions or simultaneously in groups, from some protected observing station. So far as the writer is aware, this system was first practically employed about 1874, and the current was obtained by means of pile batteries. These were formed of about 160 elements, consisting of alternate copper and zinc plates separated by fearnought (a kind of flannel) dipped in diluted vinegar. With these batteries high tension fuses were used, which were not only dangerous, but frequently failed owing to the difficulty of keeping the circuits free from moisture. From 1874 down to about 1881 gun circuits were fitted as complete wire circuits. Now earth return circuits are adopted, except in some cases of auxiliary circuits which are still complete wire circuits.

Safety Arrangements.—These are highly necessary in the ordinary working circuit, in view of the possibility of the gun being fired prematurely with possibly disastrous results. For instance the gun might by mischance be fired before the breech block was properly replaced and locked, and to avoid this danger the circuit is broken automatically by the act of unlocking the breech and the connection is again made automatically in the act of relocking after loading. Again the gun might be fired after the breech block was secured, but before the gun was run out, in which case the energy of recoil would be expended in smashing up the gun mounting. To avoid this, the circuit is automatically broken at the front end of the carriage by the action of recoil, and is remade automatically just as the gun again reaches its run-out position. The making and breaking of the circuits are effected by means of rubbing contacts, and while these give assurance against an accidental discharge of the guns, they are not an unmixed good, as they sometimes cause a miss-fire, and a continuous protected circuit without any of these breaks would be more certain and reliable. In the earlier turret ships, especially in the rigged ones, the guns were masked by portions of the ship's structure at certain angles of training. In such cases devices were introduced for automatically breaking the firing circuit at these particular angles. In all the later turret and barbette ships the turrets or barbettes are placed near the extremities of the ship, and while having a limited arc of training, they are unobstructed in their fire throughout the whole of this arc when the ship is cleared for action. Consequently, there is now no necessity for any safety arrangements. In the modern, as in earlier ships, the full depression of the guns cannot be obtained throughout the whole horizontal arc of training, and the danger of firing into the deck is obviated by an ingenious automatic arrangement, which is in connection with the hydraulic or other mechanism for working the guns, and has nothing to do with the electric circuits.

4. Electric Communication.

The efficiency and safety of a modern warship are largely dependent upon the means of communication between the various working parts of the vessel. The officer directing from the conning bridge the movements of the vessel must have the means of instantly transmitting to the engine room a few prearranged signals with regard to the starting, stopping, etc., of the engines, and he likes to have the signal transmitted back to him to assure him that his order has been correctly received and is about to be carried out. When manœuvring in squadrons, in which his ship has to keep her correct station in relation to the others, he must be able to communicate to the engine room, for regulating small variations of speed, say, one revolution more or less over a considerable range of speed. He also likes to be able to ascertain for himself on the bridge the actual revolutions of the engines, and he prefers to do this at a glance without having to take the trouble to use a watch and count the revolutions, say, for a minute. Where the steering wheel is not immediately under his own eye as it generally is when steam or other mechanical power is applied for steering the ship, he likes to have an indication on the bridge that the rudder is properly responding to the motions of the steering wheel. Should either of the alternative steering positions below have to be resorted to, he requires a certain means of communicating his orders to the steersman at that position. In addition to the means of transmitting a few prearranged signals, he also requires a means of conversing from the conning bridge with the engine room, with the steering positions, and with a few other places. In action, when the vessel's movements may be directed from a protected conning station, he needs, in addition to the foregoing requirements, to be put in communication with the officers at the various gun quarters, including turrets or barbettes, and also with those at torpedo discharging positions, etc. In fact, he requires to be placed [illegible] directly or indirectly in communication with every part of the ship where officers and men are stationed. Where only a few prearranged signals are required, these intercommunications are effected by means of transmitting and receiving instruments either mechanical or electrical; while for communications of a general character voice pipes are employed. About six years ago many complaints were received from ships as to the unsatisfactory nature of the means of signalling and intercommunication, and as many new instruments, chiefly electrical, were then being proposed for use in the navy, a committee was appointed, consisting of naval officers, naval constructors, and marine engineers, of which the writer was a member, to enquire into and report upon the whole subject. In the course of the enquiry the views of a large number of representative naval officers were obtained, in order to determine, firstly, what intercommunication was necessary and best for a ship of war. On this primary question naval officers were not wholly agreed; but there was sufficient accord to [illegible] a standard method to be laid down. In order to arrive at the best means for effecting these intercommunications, the committee studied all the methods that had been previously tried, [illegible] those in use in the mercantile marine. They carefully [illegible] and tested many new instruments that were submitted [illegible] notice, and carried out a number of independent experiments.

Voice Pipes and Call Bells.—Among other means of [illegible] the committee recommended that all voice pipes [illegible] stations where there is noise or vibration, and all others [illegible] are over 100ft. in length, should be increased from 1½in. [illegible] diameter, the size then in use, to 2in. internal diameter, [illegible] with these larger pipes a system of electrical call bells [illegible] fitted. This plan is now generally carried out in the [illegible] has resulted in greatly improving the means of communication. The call bell arrangement consists of an ordinary push [illegible] the sending station, with the well-known annunciator or [illegible] shutter instrument at the receiving station; the dropping [illegible] indicates the station from which the call has come, and [illegible] the particular pipe to be spoken through. It is found that [illegible] voice pipes communication to places where there is [illegible] tion or noise is not very satisfactory. Many devices have [illegible] and are still being tried with the object of improvement. The committee were much impressed with the immense [illegible] offered by an electrical system of communication, and, [illegible] other things, telephones of different forms were tried [illegible] tion for voice pipes. The results were not such as to lead to their introduction into the ships of the navy.

Telegraphs.—With regard to instruments, though for ships [illegible] a mechanical system has some great advantages over an electrical, yet as a means of establishing communication between [illegible] instruments at distant stations the electrical system is [illegible] away the best. The many disadvantages of a system of [illegible] and bevel wheels, led through a considerable portion of the [illegible] of a ship, scarcely need to be stated, while the great [illegible] offered by a simple insulated wire are equally self-evident. The committee therefore recommended that the one mechanical telegraph for communicating orders from the bridge or [illegible] tower to the engine room should be retained, but that the telegraph for orders respecting speed of revolution should be electrical. Many of these electrical telegraphs have been [illegible] the navy; but the reports upon them have not been [illegible] favourable, although in some instances they have been [illegible]. Whether the grounds for the unfavourable reports have [illegible] been good and sufficient is a matter of opinion; but at the [illegible] time electrical telegraphs in the navy appear to be [illegible] under a cloud, so that the field is still open for inventors [illegible] direction. The telegraphs already in use are worked by [illegible] or secondary batteries, while a new form has been proposed [illegible] be worked direct from the ship's dynamo.

5. Other Applications of Electricity.

Submarine Mines.—There are some other applications of electricity in the naval service which may be referred to [illegible] detailed descriptions. One important application is that [illegible] marine mining, whereby stationary torpedoes or mines are [illegible] by an electrical current from an observing station on shore [illegible] the position of an enemy's ship in relation to the mines [illegible] ascertained by means of range-finding instruments in [illegible] stations at a considerable distance apart but electrically [illegible]

An electrical apparatus has also been designed and experimented with for enabling a boat, without any person [illegible] sent from a safe distance into an enemy's mine field, to [illegible] and thus render harmless the mines laid there. By [illegible] the boat can be steered, the engines stopped or started, and [illegible]

countermines dropped when desired and exploded. In this way an otherwise exceedingly risky operation can be performed without danger to life; and the worst casualty that can happen is the loss of the boat only.

Night Signalling.—Electricity is also applied to night signalling. The ordinary semaphore instrument as used by day is illuminated at night by means of incandescent lamps in front of a reflector, the whole being contained in a wooden box placed at a short distance in front of the semaphore arms, which are painted white, in order to make them more distinctly visible by night in the rays of the electric lamps. Another system of night signalling has lately been introduced, consisting of four flashing lamps placed in a vertical line at topmast head. The lamps are incandescent with special filaments, and one lamp or more can be switched off at will by an arrangement of switches in the chart-house, where there are also four small lamps which follow the movement of the lamps at masthead. By a preconcerted code the combinations of the lamps are interpreted. This arrangement is intended principally for squadron sailing at night, to convey orders as to altering course, speed, etc.

Gun Sights.—The sights for guns are now adapted for night firing by employing electricity for their illumination. This is effected by means of small incandescent lamps, for which the current is obtained from a primary battery consisting of three Leclanché cells in a box secured to some part of the gun mounting. A switch is also fitted for each sight, having a resistance connected with it, so that the current can be varied at will, and thus the lights can be made more or less brilliant to suit circumstances.

Examination of Gun Bores.—An apparatus is now supplied to ships for examining the bores of guns. It consists of an inclined mirror supported in a metal frame, which is made to fit the bore, and can be pushed into any part of the bore by a long rod screwed into it. According to the size of the gun the frame carries from one to four 100-c.p. lamps, which illuminate the bore; and by the aid of the inclined mirror a close examination can be made for defects.

Motors.—The application of electricity to motors has not yet gone very far, not so far, in fact, as in some other nations it has already gone or is now going. Of the success of its application to the working of guns, supply of ammunition, etc., the writer is not very sanguine; but if results prove satisfactory, the navy will no doubt quickly profit by the experience of other nations. Electrical science is as yet in its infancy, and it promises enormous developments in the near future; so that in a few years operations may be performed by electricity which are not dreamt of now. In any case the British Navy will not fail to press into its service every development of science which will increase the efficiency of the nation's first line of defence.

COMPANIES' MEETINGS.

EASTERN TELEGRAPH COMPANY.

The half yearly general meeting of this Company was held on Friday last at Winchester House.

Sir John Pender, M.P., who presided, stated that the gross revenue for the half-year ended March 31 last had been £382,207, being a decrease of £1,100 compared with the revenue of the corresponding period of the previous year. The small decrease of £799 in the message receipts was principally caused by the loss of revenue from the reduction of the Australian tariff, and by small decreases in the receipts from other sources, notably South Africa, but these reductions had been almost counterbalanced by the growth of traffic in other directions. The total ordinary expenses for the half-year ended March 31 last had been £105,820, or an increase over those of the corresponding period of 1891 of £3,800, of which £3,692 represented the increase in the working expenses at the stations, which had amounted in the half-year under review to £78,695. The number of messages carried by them in 1891 was 1,309,755, or an increase over the number carried in 1890 of 123,387. Important improvements had been effected at several of the stations, and owing to their good condition they had considerably below the average of cases of disease. Their ships had been fully employed carrying out important works of repairs and renewals, not only on the Company's account, but also on account of the Brazilian, the South African, the African Direct, and the Direct Spanish companies. The money accruing from these repairs had given the Company about £15,000. They were able to propose the usual final dividend of 1¼ per cent., with a bonus of 1¼ per cent., making, with the interim dividends already paid, a total distribution of 6¼ per cent. for the year ended March 31, 1892, and to carry £68,000 to the reserve fund. After applying from this fund a further sum of £72,773 towards the cost of the Aden Bombay triplicate cable and other expenditure, the general reserve fund would amount to £442,014, and the total amount applied from this fund for new cables, etc., now amounted to £1,174,236. At the last meeting the shareholders approved the principle of establishing a staff pension fund, and the Directors had had a scheme prepared by experienced actuaries, who had advised that an annual contribution by the Company of 2½ per cent. on the salaries and a similar contribution by the staff would, if invested at 4 per cent. compound interest, provide sufficient funds to make adequate retiring allowances for the younger members of the staff on their attaining 60 years of age. As many of the older employés, however, had already seen considerable service, and their retirement in some cases could not be far distant, 2½ per cent. would be insufficient to place them on an equally favourable footing. With a view, therefore, to supplementing their allowances from the pension fund, the actuaries advised that, in addition to the 2½ per cent. just referred to, the Company should continue the present contribution to the endowment assurance fund in full until all the existing policies were paid off, and allow the savings effected by the premiums ceasing to be payable to the assurance company, as the policies matured from time to time, to be applied exclusively for the benefit of the older servants. The wish that the older servants should not be placed on a less favourable footing than the younger members of the staff was strongly expressed at the last meeting. The actuaries further recommended that the Company should guarantee 4 per cent. interest on the accumulations of the fund. Provision was also made in the actuarial calculations for dealing with cases of death or breaking down in health before reaching the retiring age and for other contingencies. This was a fair outline of the actuaries' scheme, but as certain details were under consideration by the Board it was proposed to ask the shareholders to approve a resolution in general terms empowering the Directors to bring the scheme into operation when the details were finally settled. He concluded by moving the adoption of the report and the payment of the dividends and bonus recommended.

The **Marquis of Tweeddale** (the vice-chairman) seconded the motion

In answer to **Mr. Sears**, the **Chairman** stated that the proposed staff pension fund would cost the Company about £2,000 a year more than they had been paying on a similar account for the last five or six years.

The motion was adopted, and a resolution was afterwards passed, on the motion of the **Chairman**, seconded by **Sir James Anderson** (the managing director), approving the establishment of the staff pension fund and authorising the Directors to carry the scheme into effect with such alterations and modifications, if any, as might be approved by them.

Replying to a vote of thanks to the Chairman and Directors, the **Chairman** expressed his gratification at the remarks which had been made congratulating him on his return to Parliament. He had had 50 years of active life, and it might be thought rash on his part to have sought being returned to Parliament again. Of course, they had no politics as a Company, but he might state that, even at his time of life, he did not want to see anything done to weaken the Empire, and he would do his utmost while any life remained in him to maintain it.

WEST AFRICAN TELEGRAPH COMPANY.

The seventh ordinary general meeting of this Company was held last Friday, at Winchester House, Old Broad-street, Sir J. Pender, chairman of the Board of Directors, presiding.

The **Chairman** said their revenue for the year 1891 amounted to £60,214, as against the takings of 1890 of £68,377, showing a decrease of £8,163. There was a decrease in the Cape joint purse and the traffic with the French stations, but this was nearly counterbalanced by increase in traffic with British and Portuguese stations, with South America, and local traffic. The principal cause of the reduction of the revenue was the serious depreciation of the Portuguese currency. As would be seen from the accounts, there had been a total loss on exchange of £7,011, nearly the whole of which was due to loss on remittances between Portugal and England. This matter had received the serious consideration of the Directors, and negotiations were pending with a view to a satisfactory settlement. They had been endeavouring to obtain the consent of the Portuguese Government to raise their rates of collection on the West Coast, and the suggestion had been favourably received, and should the change be formally sanctioned it would to a certain extent minimise the loss on the rate of exchange Fortunately, the money collected in Portuguese currency on the coast had been used for general expenses at the various stations, and the Company this year saved £2,700 loss, which would have been incurred had the money been remitted to London. The total working expenses for 1891 amounted to £20,883, against £21,685, or a decrease of £802. Several of the items showed an increase, and others a decrease, under the headings of "working expenses at stations," which were less than last year by £394, and "repairs to cables" £2,213, against £4,788, or a decrease of £2,575. The balance available for dividend and reserve fund was £12,639, against £17,570, or a decrease of £4,931. It was proposed, therefore, to pay a final dividend of only 2¼ per cent., making, with the interim dividend already paid, a total distribution of 4 per cent. for the year, and to carry the balance of £3,395 to the general reserve fund, which amounted to £30,363. The real question at the present moment was this question of exchange. He could not hold out very much hope of Portuguese finance improving greatly, but he thought they might, by raising the rate of collection, save themselves from the very serious loss which they were now sustaining. There was another feature in their business which he should like to mention, and that was that there had been a general depression over Africa. The Cape, as they all knew, had had its time of trials and depression, and they were passing through a phase of depression at the present time; but there was so much vitality in the country that he had no hesitation in coming to the conclusion that prosperity would return, which would give the Company increased revenue and profit. Altogether, while he might say that although the report was not very satisfactory, it was not very unsatisfactory, and taking the "ups and downs" which always occurred at the beginning of a telegraph system which had more or less to be nursed and developed, he thought the prospects for them in the future were

upon the whole very favourable indeed. He might add that they did not possess the healthiest stations for working this system of telegraphy, and therefore they had to be particularly careful in seeing that their staff at the stations were well looked after. They gave them comfortable homes, and did everything they could to ameliorate the conditions of the climate, and they were fully satisfied in doing so that they were not only benefiting the Company's agents, but securing for themselves a class of workers better than they could do under other circumstances. In conclusion, he moved that the report and accounts be adopted, and the dividend declared payable.

The motion was seconded by **Sir H. Mance**, and unanimously agreed to.

Sir J. Pender and Mr. R. J. Gray, the retiring directors, were re-elected.

UNITED RIVER PLATE TELEPHONE COMPANY.

The sixth annual ordinary general meeting of this Company was held on Tuesday at Winchester House.

Mr J Irving Courtenay, who presided, in moving the adoption of the report, referred to the extremely critical period which this Company, in common with all others in the River Plate, had had to pass through during the past 12 months. Though it might be considered rash to attempt a forecast, still, he strongly inclined to the opinion that matters, both financial and political, in the River Plate had seen their worst. The gross income from the River Plate for the period under review was £98,690, against £106,259 in the previous year. This difference was, to some extent, caused by a falling off in their subscribers between March, 1891, and the same month this year; but he might say it was mainly due to their writing off over £5,000 for subscriptions which their Buenos Ayres managers had recommended. Some of these might yet be recovered. Notwithstanding the economies that had been effected, their expenses in the River Plate had slightly increased. The principal cause for this was the augmented cost of materials and other necessaries requisite for carrying on the ordinary business of the Company. The loss on exchange for the year ended March 31 last was £31,741, an amount nearly representing 11 per cent. on the Company's paid-up share capital. The gross receipts amounted to, say, £98,700 and the whole of their expenditure in the River Plate was, in round figures, £58,000, thus leaving a profit in paper dollars, the par value of which was £40,100. They were compelled to remit this profit home to pay debenture interest and other expenses in sterling, and in so doing they lost on exchange £31,700, which left them a balance when received in London of £8,400 to meet these expenses. In the London outlay they had made a considerable reduction. They thought that the working for the current year would be much more satisfactory than it had been for the previous 12 months, because of a substantial increase in the number of subscribers and the fall of the gold premium from an average of 280 to 223 per cent. The capital outlay for the year had been extremely small—£1,008. At the same time their plant had been well kept up. At Rosario, in consequence of the introduction of the electric light, special appliances had been provided to guard against any damage resulting from contacts.

Mr F W Jones seconded the motion, which was carried.

GLOBE TELEGRAPH AND TRUST COMPANY, LIMITED.

The nineteenth ordinary general meeting of this Company was held at Winchester House.

Sir John Pender M P, who presided, stated that for the year ending the 18th inst. their receipts showed a decrease, as compared with those of the previous year, of £9,455, after paying expenses. They had received £2,184 less on their investment in the Anglo-American Company, £3,823 less from the Brazilian Submarine Company, and no dividend from the German Norwegian Company. They had also received somewhat smaller dividends from the West African and the Western and Brazilian Companies, the diminution together amounting to about £1,000. Nevertheless, the sum they were able to divide was only £7,697 smaller, owing to the large balance brought forward in 1891. They had a dividend to recommend on the present occasion of 1½ per cent. for this year, compared with 5¼ per cent. for the previous year. Their preference and ordinary shares, taken in like amounts, showed a return of £5. 8s. 9d. per cent. The money reinvested in the West Coast of America Company had so far given no return, but the prospects of dividend from this source were very promising. A line was now being constructed across the Andes which would bring the Brazilian Submarine Company into communication with the Pacific coast, and they then expected to see a considerable increase of traffic, not only for the Western and Brazilian Company, but also for the West Coast of America line. The Brazilian Submarine Company had paid them £4,000 less than they did in the previous year. That company was building up its reserve fund, but they hoped it would soon return to its former dividend. The dividend, however, which they at present received from the Brazilian Submarine Company was equal to a return on this investment over 7 per cent. They had a large amount of capital in the Eastern and Eastern Extension Companies, which showed good returns, yielding together a dividend to the Globe Company of over 6½ per cent. Their shares in the American Cable Company gave them a return of 5¼ per cent., and their Western Union shares yielded them £5. 17s. 5d. per cent. and had improved in value. With the general growth of telegraphy—and telegraphy must grow—their dividend would improve. After referring with regret to the death of the late secretary, Mr. William Payton, and of Mr. William Ford, a former member of the Board, he concluded by moving the adoption of the report.

The **Marquis of Tweeddale** seconded the resolution, which was unanimously carried.

COMPANIES' REPORTS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald Lodge, Stanmore; Charles Seymour Grenfell, Esq., [illegible], Taplow; Sampson Hanbury, Esq., Langford Park, Maldon, [illegible] S. Barclay Howard, Esq., Hatfields, Loughton, Essex; [illegible] Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the Directors for the half-year ending June 30, 1892, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Friday, August 5, at 3 p.m.

The receipts during the half-year from all sources amounted to £21,520 4s. 8d., and the cost of working for that period to £15,097 13s. 2d., leaving a profit of £6,422 11s. 6d. Including the balance brought forward from last year, the net revenue account shows a total of £7,348 19s. 9d. After providing the debenture interest amounting to £1,317 7s. 4d., there remains a balance available for dividend of £3,031 12s. 5d., out of which your Directors recommend that the full dividend of 5 per cent. per annum be paid on the perpetual preference shares, and they further recommend that a dividend at the rate of ½ per cent. per annum be paid on the ordinary shares, leaving a balance of £983 2s. 2d. to be carried forward to the next account. The number of passengers carried by the railway during the six months, exclusive of season ticket holders, was 2,813,162, showing an increase over the corresponding period last year of 400,819. The steady decrease in the expenses alluded to in previous reports has been satisfactorily maintained, notwithstanding a considerable further increase in the [illegible] paid for rates and taxes. The rolling stock and plant have been efficiently maintained, and are in good working order. The fourth generating engine and dynamo are erected [illegible] for use. Arrangements have recently been made by which the public are allowed to view the generating station on payment of a small charge, and this privilege is being availed of to a considerable extent. During the past session a Joint Committee of the two Houses of Parliament was appointed to consider and report upon the best method of dealing with the various electric and cable railway schemes in the Metropolis proposed to be sanctioned by Parliament. They reported strongly in favour of electricity as a motive power, and made some valuable suggestions for the extension of railways of this character. The successful working of this line had no doubt great influence in inducing the committee to make so favourable a report. Owing to the dissolution of Parliament, the Bill promoted by this Company for the extension to Islington and other purposes could not be proceeded with further than the second reading in the House of Commons. The Directors therefore decided to take advantage of the resolution passed by both Houses by which all private bills are carried over to next session, when they will be proceeded with at their present stage. The urgent need of additional [illegible] accommodation at Stockwell Station to meet the requirements of growing traffic renders it desirable that this work should not longer be delayed. To meet this expenditure it will be necessary to issue some additional preference shares. A resolution to that effect will be submitted at the special meeting. Your Directors being of opinion that the time has now arrived when the present terminable debenture mortgage bonds should be converted into perpetual mortgage stock, propose to ask the shareholders for authority to carry this out, and a resolution will be submitted at the special meeting for the issue and creation of debenture stock to the extent of the authorised borrowing powers of the Company. It is hoped that a considerable saving in the interest charges will be effected by the operation. Your Directors have to announce with great regret the death of Major Kitson, who has been one of the auditors since the commencement of the railway. Notice has been received from a large shareholder of his intention to propose Mr. James [illegible] Oliver to fill the vacancy thus created.

CROMPTON AND CO., LIMITED.

Directors: H. H. J. W. Drummond, Esq.; Bernard [illegible], Esq.; Viscount Emlyn; Carleton F. Tufnell, Esq. Managing Directors: Rookes Evelyn Bell Crompton, Esq., and John Francis Albright, Esq.

Fourth report of the Directors, to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon-street, E.C., on Friday, the 29th July, 1892, at 2.30 p.m.

The Directors have pleasure in submitting to the shareholders the fourth annual statement of accounts and balance-sheet made up to the 31st March last, to report that the business of the Company continues satisfactory, and that the reorganisation and additions to the Chelmsford works have proved a great advantage in increasing the output and reducing the cost of manufacture. In order more effectually to separate the account for the electric lighting of Chelmsford from the manufacturing and other accounts of the business, the Directors have caused to be registered the Chelmsford Electric Lighting Company, Limited, to which company the

general meeting early next year to place the Company in voluntary liquidation, and to authorise the distribution of the capital."

Anglo-American Telegraph.—The report of the Directors states that the total receipts from January 1 to June 30, including the balance of £864 brought forward from last account, amounted to £147,818. This sum, however, is subject to revision, as the law suit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal in Paris. The traffic receipts show an increase of £10,035 as compared with the corresponding period of last year. The total expenses of the half year, including the repair of cables, etc., amounted to £59,364. One quarterly interim dividend of 12s. 6d. per cent. on the ordinary stock and of £1 5s. per cent. on the preferred stock was paid on April 30, absorbing £43,750, and a second quarterly dividend at the same rates will be paid on July 30, leaving a balance of £954 to be carried forward to the next account.

New Telephone Company.—Messrs. N. M. Rothschild and Sons are authorised on behalf of the New Telephone Company, Limited, to receive subscriptions for 48,800 ordinary shares of the Company of £10 each at par. The Company was formed in 1885 with a nominal capital of £750,000 divided into 74,700 ordinary shares of £10 each and 3,000 founders' shares of £1 each, the latter entitled to one half of the surplus profits after the payment of a dividend of 7 per cent. on the ordinary shares. Of the 74,700 ordinary shares, 1,500 were issued on the formation of the Company, and the present issue is for the balance—73,200 shares—of which one third is to be subscribed for at par by the National Telephone Company, Limited. The New Telephone Company is the possessor of a license granted by the Postmaster-General for the establishment of telephone exchanges and communications in the metropolis and throughout the United Kingdom, but the Company has been unable to develop its undertaking until the Telegraphs Act of 1892, which received the Royal assent on June 28 last, placed it in a position to deal satisfactorily with the telephonic requirements of the country.

London County Council. The Council met on Tuesday at Spring gardens, when the following tenders were received for the electric lighting of Claybury Asylum (contract No. 1).

Woodhouse and Rawson	£13 970
F. M. Newton	14 105
Latimer Clark, Muirhead, and Co., Limited	15 130
Brush Electrical Engineering Company, Limited	15 800
Appleton, Burbey, and Williamson	16 500
J. E. H. Gordon and Co., Limited	17 337
Crompton and Co., Limited	17 500
Edmundsons, Limited	17 737
J. G. Statter and Co.	18 128
Sharpe and Kent	18 540
Bourne and Grant	18 808
Manchester Edison Swan Company, Limited	18 850
Johnson and Phillips	19 200
Mather and Platt, Limited	19 250
Hammond and Co.	19 900
Electric Construction Corporation, Limited	19 932
Drake and Gorham	20,500
Fowler, Lancaster, and Co., Limited	20 549
J. D. F. Andrews and Co.	21 000
Paterson and Cooper	22 540
Rogers' Electrical Engineering Company, Limited	23 966
R. Verity and Sons	26 471
Laing, Wharton, and Down	27 982
Siemens Bros. and Co., Limited	28 400

The tenders were referred to the Asylums Committee.—*Contract Journal.*

PROVISIONAL PATENTS, 1892.

JULY 18.

13,134. **An improved form of voltmeter.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion street, Clerkenwell, London.

13,146. **Improvements in microphones.** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London.

JULY 19.

13,160. **Increasing the efficiency of telephonic communication and transmitting speech.** Thomas Oddy, River street, Rochdale.

13,167. **Electric arc lamp.** William Edwin Irish, 36, Chancery lane, London. (Complete specification.)

13,207. **Improvements in incandescent electric lamps.** Louis Stein, 17, Southampton buildings, Chancery lane, London.

13,218. **A process for covering or insulating submarine cables and underground installations and other purposes.** Tom Sumner Lemon, 35, Sebert road, Forest Gate, London.

13,221. **Improvements in or connected with telephones.** Wilhelm Deckert, 4, South street, Finsbury, London. (Complete specification.)

JULY 20.

13,288. **Improvements in connections for electroliers and other electric light fittings.** Hugo Hirst, 11, Furnival street, London.

JULY 21.

13,323. **Improvements in or connected with the production of electric energy.** Henry Clay Bull and George Bell Cowl, 15, Water-street, Liverpool.

13,335. **Improved means for signalling by electricity on [illegible] ways.** Thomas Whittingham, 128, Colmore row, [Bir]mingham.

13,337. **Improvements in electric belts which impro[ve] ... are also applicable to other purposes.** George [illegible] Harness, 20, High Holborn, London.

13,338. **An improved switchboard.** Sir Charles Stewart [Forbes,] Bart., 21, Finsbury pavement, London.

13,358. **Improvements in or relating to alternate[-current] circuits.** William Morris Mordey, 46, Linco[ln's Inn] Fields, London.

13,375. **Improvements in or relating to electric meters, [measur]ing apparatus, and controlling gear.** Wilfrid L. [illegible] The Elms, Seymour grove, Manchester.

13,380. **Improved means of preventing injury to te[legraph] cables connected with lightships and floating [illegible]** Frederick Le Breton Bedwell, 166, Fleet street, Lo[ndon].

JULY 22.

13,381. **Improvements in the manufacture of electrical [illegible] plates, cells, or accumulators and the acc[essories] thereto.** Edward Brailsford Bright and Lewis [illegible] Mercier, Archway House, Esher, Surrey.

13,389. **Improvements in voltmeters.** Frederick Bro[illegible] Bridge street, Walsall.

13,395. **Improvements in or relating to electrical ap[paratus] for signalling.** Maunsell Mercier, 5, Deansgate, [Man]chester.

13,405. **Improvements in portable Leclanche batteries.** [illegible] Nehmer, 4, Grafton street, Gower street, London.

JULY 23.

13,453. **Improvements in electrodes for use in elec[trical] apparatus, and in their manufacture.** Godfrey [illegible] 17, Holborn, London.

13,473. **Improvements in apparatus for heating purpo[ses and] cooking by means of electricity.** Gustav [illegible] 11, Furnival street, London.

SPECIFICATIONS PUBLISHED.

1891.

6,072. **Electro heating apparatus.** Carpenter. (Second [edition.])

11,108. **Electric batteries.** Coad.

11,526. **Electric lamps.** Adams.

11,548. **Conductors for electric propulsion on perman[ent way].** Prokofiew.

11,630. **Ribbed metallic plates for secondary batteries.** [illegible]

13,124. **Heating and welding by electricity.** Howard. [(Second] edition.)

14,097. **Telephone transmitters.** H. L. and J. Todd.

14,236. **Generating and distributing electricity.** L[illegible] Pritchett.

14,266. **Administering electricity to horses.** M. and [illegible] Humm.

14,508. **Arc lamp.** Warburton.

15,483. **Electric lighting.** Mewburn. (Sec.)

17,426. **Generating ozone by electricity.** Andreoli.

1892.

785. **Incandescent electric lamps, etc.** Ries.

4,910. **Telephone apparatus.** Lockwood.

4,617. **Electrical attachments for pianos.** Feldkamp and [illegible]

9,056. **Electrically giving reciprocating motion.** McKa[y.]

9,379. **Electrically heating and working metal bars.** [illegible]

9,409. **Electromagnets for organs, etc.** Binns.

9,815. **Foot supports for telegraph poles, etc.** Stocker.

9,883. **Electric motors.** Thompson. (Collan.)

9,947. **Electric conducting wires.** Haddan. (Grammont.)

9,983. **Propelling railway vehicles by electricity.** T[illegible] (Ries and another.)

10,133. **Electrical insulators.** Brandau.

10,230. **Electric condenser.** Lord Kelvin.

NOTES.

Tonbridge.—Electric communication is to be put in the new hospital of the Tonbridge Board of Guardians.

Telephone Patents.—The Belgian Bell Telephone Company has gained its suit against the English Edison Company.

Tommasi Accumulators.—A company has been formed in Paris to manufacture Tommasi's multitubular accumulators.

Zurich.—A 400-h.p. station is being erected at Macerata, says *Industries*, by Messrs. Escher, Wyss, and Co., and the Oerlikon Company.

Limburg, on the Rhine, celebrated for its strong cheese, is to have a Lahmeyer central station, with power transmitted a mile from the River Lahn.

Sherborne.—A horse and carriage show is being held at Sherborne, commencing yesterday. Mr. E. R. Dale is exhibiting electric cycle and carriage lamps.

Book Received. — We have received from Messrs. Spon the second edition, thoroughly revised, of "The Electrical Engineer's Pocket-Book," by Mr. H. R. Kempe.

Asylum.—The great asylum at Wadsley, near Sheffield, is to be extended. This is a building where electric light would be efficacious. It is under the West Riding County Council.

Eccles.—At the last meeting of the Eccles Local Board, a committee was formed to take the necessary steps to obtain a provisional order for supply of electric light in the district.

Crystal Palace School.—Mr. Latimer Clark will take the chair at the award of certificates of the Crystal Palace School of Practical Engineering in the Palace on Saturday, at 1 p.m.

Croydon.—The Croydon Town Council have received an offer from a company to take over their provisional order, but do not feel disposed to let their powers for electric lighting go out of their own hands.

Use of Destructors.—At the British Association Prof. Forbes read an interesting paper on the use of destructors in conjunction with high-level water accumulators, especially connected with the lighting of Edinburgh.

Baden Railway.—The German Minister of Commerce has been asked to sanction the conversion of the Baden steam tramway to an electric tramway. It is proposed to extend the line to Vöslau, and use the power station to line the town.

Chadwell Heath.—The Barking Gas Works has the right of supplying gas to this district, but it is rather out of the way, and so gas cannot be obtained. Some suggestions have been made for public or private enterprise to introduce the electric light.

Barnsley.—Mr. J. C. Stott, in the Barnsley local paper, objects to the Corporation having 10 times the present light, as they propose. He thinks one and all agree Barnsley is now thoroughly well lighted. Fortunately, the Council do not agree to this.

Journal.—We have received the *Journal* of the Institution of Electrical Engineers, containing paper and discussion on the "Newcastle Electric Supply," by A. W. Heaviside and R. C. Jackson, and on "Commercial Electrolysis," by Jas. Swinburne.

Bournemouth Tramways.—The Bournemouth and Poole Tramways Company have had the time authorised for commencement of work extended to two years from August 4, 1892. We believe an attempt is to be made to run them by electricity, as electricity is already in favour in the town.

Wigan.—A circular from the town clerk of Wigan was read at the meeting of the workhouse authorities asking if the Board were desirous of being supplied with the electric light. It was decided to answer the communication in the negative. Electric light is yet too much of a luxury to be applied to workhouses.

Free Telephones.—The National Telephone Company are acting on a generous and spirited policy by giving free connections at Cheltenham to the Children's Hospital, the General Hospital, the District Nursing Society, the Eye, Ear, and Throat Infirmary, the Gordon Boys' Brigade, the Fire Brigade Station, and the Police Office.

Electric Traction.—The *Street Railway Gazette* is responsible for the statement that of the 400 street railroads in the United States, more than half have adopted electricity as motive power. In no other industry—except perhaps corn-milling on the introduction of the roller system—has such a radical and extensive transformation taken place in so short a time.

City Guilds College.—We are pleased to call attention to the notice of the classes at the City and Guilds of London Institute, which commence at the end of September. We have often expressed our opinion on the usefulness of these institutions, and a two years' course, followed by practice in the shops, will enable a sensible, painstaking student to qualify himself for a career as a practical scientific man.

Niagara.—We have good authority to state that the reported offer to Prof. Unwin to accept the position of chief engineer to the Niagara transmission scheme at over £5,000 a year is perfectly true. It is equally true that he has refused this tempting offer (which would have placed him certainly at the head of the practical engineers at one bound), preferring to remain at the Central Institution and continue his educational work there.

Southend.—The Southend Pier is to have a telephone. A report has been received from Messrs. Crompton with reference to the electric appliances on the pier. The Board of Trade circular with reference to the electric lighting order elicited the information from the chairman of the Local Board that the provisional order was not yet in danger of running out. The tender of Messrs. Crompton, at £18. 16s., for connections to old trams was accepted.

Loss of a Dynamo.—Mr. Alfred Crofts, of St. James-street, Dover, says that at the close of the Electrical Exhibition, Crystal Palace, one of his exhibits—a small unwound dynamo at 208, South Gallery—after being packed, mysteriously disappeared, and the efforts of the Crystal Palace staff have failed to trace it. As it may have accidentally been taken in mistake with some other exhibitor's packages, this notification of the loss may assist in finding the errant machine.

Heckmondwike.—At the meeting of the Heckmondwike Board of Health last week, the Electric Lighting Committee sent in a modified recommendation "that the Board be recommended to consider the propriety of lighting the town by electricity," instead of, as before, that they "should put down the necessary plant" at once. But Mr. S. Wood gave notice that he would move a resolution at the next meeting authorising the Board to put down the necessary plant.

Portsmouth.—Tenders will be invited for the Corporation central electric station at Portsmouth before very long. The building contracts will be, of course, required first, but the engineering and electrical tenders will not be far behind. Mr. Manville, the consulting engineer to the

Portsmouth Corporation, has been busy for some time on the detailed plans, and the sanction of the Local Government Board for power to borrow is expected shortly The system, it will be remembered, is that of the high-tension alternating current with sub-transformer stations under the streets.

Cyclists' Camp. — The great cyclists' meeting at Dorking which is being held this week, is enlivened at night by the electric light. The Hammersmith club have a practical man or two, apparently, in their ranks. They took down a dynamo and an old engine obtained from somewhere, and started the light—or rather didn't start it, for the engine fell to pieces, or at least would not work. Then there was a hunt all over the district for steam power, and a traction engine was at last requisitioned. The light then went well and steadily, and the scene, with the Sultan of Morocco and other fancy dresses of the merry cyclists, was a grand and enchanting spectacle.

Bacup.—At the monthly meeting of the Bacup Town Council last week, the town clerk reported that he had sent out 194 circulars to millowners, tradesmen, and others with a view to ascertaining whether they were willing to take the electric light; 44 answers had been received, representing about 500 gas lights, in which the major portion expressed their willingness to adopt electricity in lieu of gas, provided the charge did not exceed 6d. per unit. The Council considered the result unsatisfactory, and instructed the town clerk to communicate with the parliamentary agents with a view to securing an extension of the Corporation's provisional order, 1890.

Associated Chambers of Commerce.—An interesting occasion for meeting on business and pleasure will be the visit of the Associated Chambers of Commerce to Newport during the week beginning September 19th next. Sir Albert K. Rollit, M.P., will be chairman. A business session and inspection to the docks will occupy the first two days, and the last three will include excursions, amongst which will be a visit to the famous Risca and Abercarn Collieries, which are electrically fitted. The works of the Ebbw Company, the Crumlin Viaduct, Tintern, and Monmouth will also be visited. On Saturday an exploration of the available land for the wharves and docks on the River Usk will be made, and the harbour and port of Newport will also be inspected.

Coast Communication.—In commencement of the system of establishing telegraphic and telephonic communication around the British coast the telegraph steamer "Monarch," with Lieutenant Williams, R.N., and Mr. Lumsden, the electrician, on board, arrived at Scilly on Tuesday afternoon, and on Wednesday commenced the work of connecting the coastguard stations at St. Mary's, St. Agnes, Bryher, Tresco, and St. Martin's. Before darkness set in they had laid a submarine cable from Bryher to Tresco, and from the Cove at St. Agnes to about half way to Porthcressa Beach at St. Mary's, where they have buoyed the end of the cable for the night Operations were resumed next day. This communication will be of the greatest value for conveying news of wrecks to the lifeboat stations at night or during the prevalence of fogs.

Brighton.—We are glad to learn that the central station is being well supported, installations being added with great freeness. We are not so pleased to hear (except from the point of view that it shows extension) that it will be necessary to reopen the streets for the addition of a third cable to convert it at this stage to a three-wire system. Moreover, whatever else is lighted, one would think that the esplanade and pier should have electric light, yet none is seen. A recent view in the illustrated papers showed gas burners in full force, and this view is used, we see, even now as an advertisement of Sugg's burners. Brighton, the richest watering place in the South, and no public electric light! It is hardly believable. The rate of charge for the current is 7d. a unit, and not much is yet done with day load—we hope some motors will be got to work to fill up the load.

Dublin.—The Dublin Corporation, last Friday, had before them the question of handing over the electric light station to the contractors to carry on, and the duration of the appointment of electrical engineer. After being amended to include reference to their lawyer, the Council adopted the amended resolution, as follows: "That the report of the Electric Lighting Committee be adopted with the addition, that instead of being compelled to accept the tender of Messrs. Hammond and Co., the committee shall have power, if they see fit, under the advice of their law agent, to enter into a contract for running the station, and consenting to any extension of it, for one year, with Messrs. Hammond and Co.; with any other contractor or contractors; or if they see fit the committee may undertake to carry out the running of the station themselves, employ workmen, purchase materials, and do all that is necessary in the matter; and that the employment of Mr. Ruddle be for 12 months only."

Cathedral and Church Lighting.—St. Mary's Roman Catholic Cathedral at Newcastle-on-Tyne was reopened on Sunday by the Very Reverend John Vaughan, of Westminster, and in the evening was lighted for the first time by the electric light. We understand that this is the only Roman Catholic cathedral, except St. Sylvester's in Rome and one in France, which is so lit. The installation has been fitted by Messrs. R. J. Charleton and Co., of Newcastle-on-Tyne. We have recently mentioned the case of a church being lighted from a mansion. A similar installation has also just been carried out by the above firm at Prudhoe Hall, near Newcastle-on-Tyne, in connection with which there is a Roman Catholic church. The number of lights at Prudhoe, including the mansion of Mrs. Liddell, the stables, outhouses, etc., and the church adjoining, is equal to about 280 16-c.p. lamps. The power here is obtained from a steam engine and large Lancashire boiler. There are two batteries of E.P.S. cells, 31 L type, and the fittings inside the house are very handsome. The installation has given much satisfaction to all concerned.

Carlow.—A communication from Messrs. J. E. H. Gordon and Co. was before the Carlow Town Commissioners at their last meeting, asking that the time for which they should have the exclusive lighting of the town should be extended from 21 to 42 years. This was in view of the intention of Messrs. Gordon to erect steam engines for the perfection of the present system of lighting at considerable expense. To this request the Commissioners replied asking if the company would, within 10 years, have the wires put underground instead of overhead. Messrs. Gordon, however, wrote saying it was impossible to give this guarantee. The chairman and others were in favour of giving the extension in consideration of the expense incurred, though Mr. Shackleton said he did not care to hand over the town for 42 years. The chairman said they had now obtained an excellent system of electric lighting, and as a result of it they had directly caused the gas company to make three reductions in the price of gas amounting in all to 1s. 6d. in 1,000ft. Mr. Johnson proposed that the time be extended to 42 years, and this resolution was passed.

Taunton.—So Taunton has come safely through the crisis, and has adopted the scheme for purchasing an-

altering the present installation to possess their own central station. Everyone will be pleased to hear that the town which has done so much for the spread of electric lighting has carried out this resolution. A special meeting was held on Tuesday, the Mayor, Alderman Chapman, presiding, when the Electric Lighting Committee presented a report, which is given elsewhere, in which they recommended that the amount necessary be raised by borrowing for a period of 50 years, or such other period as the Local Government Board would grant. The amount which it is proposed to expend is £14,000. Of this £9,300 will be devoted to the purchase of the works in the manner recommended in the second report of Mr. G. Kapp, while £1,900 will be expended in the substitution of underground for overhead wires, with the addition of seven new lamps; £1,000 of the total will be set apart as working capital. The Council adopted this report. It was formally agreed to apply to the Board of Trade for a license, and the Mayor signed a memorial to that effect.

Horse Racing by Electric Light. — We have recounted how electric horse-racing is carried out by wooden horses driven by electric motors in France, but at St. Louis they have the real thing by electric light, and according to the *Daily News*, it has been a great success. The course at South Side Park presents a curious appearance—the stand, fences, posts, and everything paintable about it being of dazzling whiteness. In the glow of the bright lights, the effect is very striking. At a height of 20ft. from the ground runs a wire strung like the trolley wire of an electric railway round the course. Upon this, at intervals of 25ft., are strung clusters of incandescent lamps, with four lights in each cluster. Giant searchlights illuminate the turns. A peculiar arrangement prevents the casting of shadows, which has always hitherto proved the difficulty in horse-racing by artificial light. The grand stand is a blaze of brilliant whiteness, and from it the course is seen mapped out in a light so bright that the colours of the jockeys' jackets are plainly visible. The effect is all the more intense from contrast with the space of darkness that intervenes between the stand and the track. To obviate danger, only five horses are allowed in each race. The only difficulty experienced at the recent meeting was to find sufficient accommodation for the large number of horses entered.

Cardiff.—A meeting of the Lighting Committee of the Cardiff County Council was held on Tuesday, Councillor Vaughan presiding. The town clerk (Mr. Wheatley) and the borough engineer (Mr. W. Harpur) were also present. The report of the sub-committee appointed to make enquiries with a view to securing a suitable site for an electric central station was read. From this it appeared that their efforts to secure land in a suitable locality had failed, the prices asked being prohibitive in some cases, while in others there seemed little prospect of the offers made on behalf of the Corporation being accepted without a serious delay taking place. The members, therefore, were obliged to search for a somewhat less desirable place in other directions, and they suggested the advisability of utilising a piece of ground owned by the Corporation on Canton Common, about an acre in extent, adjoining the Great Western Railway. The report was confirmed, and a resolution passed recommending the Corporation to adopt the suggestion of the sub-committee. It was further resolved that Mr. W. H. Massey, their consulting electrical engineer, be requested to state the terms upon which he would prepare the necessary plans for obtaining specifications and estimates of the proposed works, also the amount of out-of pocket expenses he had incurred during the time he had acted for the committee.

Huddersfield.—An electric transformer sub-station will be erected in connection with the lavatories to be constructed underneath the old Market-place at Huddersfield. At the Huddersfield City Council meeting last week some questions were asked with reference to the price to be charged. Councillor Stocks pointed out that the Council proposed to charge 6d. a unit to begin with, which was equal to 5s. per 1,000ft. of gas. They hoped to reduce it eventually to 5d. Councillor Chrispin said that at some places they were supplying the light at 4d. a unit. Councillor Stocks doubted this; the lowest they could find was at Newcastle, where the price was 4½d. a unit. Councillor Walker wished to know whether, as the sewage works were to be lighted, the neighbouring mills could be lighted from the same source. It may be worth while on our part to point out that now the electric light is being introduced, interest will be great in Huddersfield, and as the woollen mills are scattered over a wide district, many of them out of reach of mains, there should be a fine field for separate installations. We know the ground has been pretty well canvassed for long, but it is only lately that real interest has been taken in the subject. Many of the mills being almost as large as villages, considerable caution has been necessary on the part of the owners. As a rule, the storehouses are in the town itself, and the mills are on the outskirts and even quite in the country.

Chelmsford.—Messrs. Crompton and Co. seem to be doing all they can to make the lighting of their town a perfect success—worthy of a visit from any deputation or engineer. They have secured the distinction of having lighted the first town which is dependent entirely for its public lighting on electricity. The responsibility for initiating, for carrying out and maintaining the light has been borne by them, but the time has now come when this pioneer installation shall be handed over to a separate company. Messrs. Crompton have informed the Lighting Committee that a separate joint-stock company, called the Chelmsford Electric Lighting Company, had been formed, and that they proposed to transfer the lighting of the town to them. The committee recommended that this course should be agreed to, provided that two independent sureties be submitted by Messrs. Crompton for the due performance of the remainder of the contract. They also reported that Messrs. Crompton were intending to fit new arc lamps in the town. Alderman Brown in presenting the report said the matter had been gone into very carefully, Messrs. Crompton themselves offering to become guarantors for the new company. The town clerk read a letter from Messrs. Crompton, in which they stated that the Chelmsford company had been incorporated to meet the requirements of the Board of Trade that the lighting accounts should be separately kept. The report was adopted, on the understanding that Messrs. Crompton and two independent sureties became guarantors for the due performance of the contract. We wish the undertaking success.

Brussels.—The following is an abstract of the remarks of the committee on the tenders for Brussels: Six tenders were received on October 30th last from Siemens and Halske with the Allgemeine Company, Schuckert with Bouckaert of Brussels, International Company of Liege, India Rubber Company, Crompton and Ferranti. The Siemens and Schückert schemes were for central station, continuous current and batteries, and two secondary battery sub-stations (at Quartier Leopold and Avenue Louise) with armoured underground mains. Schuckert presented a second scheme, in which the sub-station at Avenue Louise is for alternating currents obtained from direct-current motors. The International Company differs

from the two preceding ones by not using batteries in the central station. The engines would be 500 h.p., and the mains paper-covered (Bergmann system). The India Rubber Company propose a single station with 500 h.p. engines, plus a 125-h.p. engine for daily supply, mains on the draw-in underground system, with insulated cables in iron pipes. Cromptons propose both continuous and alternating current high speed engines, and small battery of accumulators with secondary station at the Theatre du Parc, and alternate currents from the central station to Avenue Louise. The Ferranti project proposes alternating currents only. The station at the gas works at Laeken would send current at 2,400 volts to a distributing station, branching off to sub-stations for transforming down to 100 volts. The India Rubber Company's scheme was considered to have most corresponded with the desires of the committee.

Edison-Swan Patents.—The Commissioner of Patents (U.S.), we learn from the American papers, has decided a long-standing controversy between Thomas A. Edison and Joseph Wilson Swan, in favour of the latter. The matter in contention was as to the priority of right to a patent for an electric light carbon for incandescent lamps. The dispute had been pending since 1881. Swan laid claim to having invented the parchmentised paper in March, 1880. He filed his application in April following, and the patent was issued in October following. Edison did not file his application until May, 1881, but he said that he had made and used the invention as early as 1879. Edison asserted his claim under the provision of law which entitles the inventor to his product as soon as he discovers it, and not from the date of his application for a patent. In 1881 Edison filed the following issues of interference: "1. A carbon formed from a straight strip of cardboard paper or parchment paper, and bent to the form of an arch, hoop, or loop, and carbonised by heat while in a bent condition. 2. A carbon for an electric lamp made of the carbonised parchment paper." On these testimony was taken on both sides, and for a time a spirited legal battle was waged. The Westinghouse people took an active hand, for at that time they thought that the parchmentised paper would continue to be of invaluable profit to them. Electrical genius, however, was too fertile to stop at parchmentised paper as the best material for incandescent lamps, and in a few years there were a half-dozen new patents that were considered superior to it. Since that time the case has lagged, not being considered of any material commercial value. Still, we must congratulate Mr. Swan upon his moral victory.

Electrical Work in Mines.—It is nearly 12 months ago since Mr. Albion T. Snell read a paper before the South Wales Institute of Electrical Engineers on "Electrical Work in Mines," which created a great deal of interest. Mr Snell went very fully into the practical outlook of the application of electricity in mines, and the discussion of the paper, which has been put off from meeting to meeting, took place at the annual meeting at Cardiff on Friday last. Mr. Albion T. Snell, in opening the discussion, said when they considered that the easily won coal in the majority of collieries had been got, that a greater depth had to be gone to, and that the forces at disposal were somewhat inadequate, he thought all would be prepared to admit that there were still further means necessary for getting and for hauling coal to compete with foreign countries. Electricity was a force capable of greater efficiency than either compressed air, steam, or ropes, which might here be efficiently applied. There were certain difficulties, such as "sparking" and "firing" when the cables were broken; these difficulties had, however, been overcome. Experiments had been made by encasing the parts where sparking occurred in explosive mixtures, and the explosion had not been communicated outside the casing, and the second risk had also been dealt with. Mr Bailey thought what was wanted to deal with sparking was to get rid of it altogether. Until that were done he was afraid it would have a very deterrent effect in the universal use of electricity in mines, especially fiery ones. In his opinion, the cables should be armour-cased and buried, and then he did not see any danger of breakage. Mr. Sydney Walker wrote, observing that it would be better not to have any armour; plenty of jute would give the same result, at a fraction of the cost and without the danger. Mr. Howell thought the best reply to Mr. Walker was that for 30 years every Atlantic cable had had armour casing. The only way, in his opinion, to avoid the breakage was to make the cable sufficiently strong to stand any strain. Mr Archibald Hood did not think there was a more important subject for the institute to discuss than this transmission of power underground. He had been averse to it at first, but since he had employed it he had determined to increase its application. He had, perhaps, about half-a-dozen electric pumps working underground, and the results in every case were highly satisfactory. Thanks were accorded to Mr. Snell for his valuable and interesting paper.

Geissler Tube Lighting.—A bit of red-hot wire did not look, in the early days, a very promising object with which to reform our system of artificial lighting. Nevertheless, with the efforts of De Changy, Sawyer and Man, Swan, Edison, and the later experimentalists, we have one of the most useful pieces of apparatus of modern times. Of what does it consist? A piece of blown glass, two platinum wires, a carbon wire, and last, but not least, a vacuum. The latter is better defined as a freer path for molecules to vibrate, and although in the present lamp we ignore the molecules, yet in the vacuum tube lamp that may come the "darling little molecules" (as the lady listener at Joseph Cook's lectures called them) will have their full play usefully applied. Given an exhausted tube and a sufficiently high potential current, vibrating sufficiently rapidly—a million or two times per second—the molecules are knocked about together and their surfaces (at least we can imagine so) become incandescent. Surface incandescence is known as phosphorescence, and free molecules of gas are a useful medium for obtaining this glow-worm light. If the Cuban maiden can light her cap with half-a-dozen glow-worms—if the Cuban pressman can pen his note by the light of a handful of these ugly but intensely interesting caterpillars—there is no reason in the world, save the possibility, why we should not attempt to utilise electric phosphorescence seen in the Geissler tubes, multiplied a hundredfold or so, as a useful light. It remains to be proved whether such a light is efficient. We have recently seen some experiments carried out by Messrs. Pyke and Harris, of Westminster, bearing in an interesting manner on this question. The current from the ordinary 110-volt circuit was taken, led through two carbons, giving a feeble arc, taking four or five amperes. This, led into a moderate-sized box, containing a transformer and tinfoil and glass plate condenser, lighted up a special kind of vacuum tube in a very brilliant manner. Mr. Pike has thus lighted, he says, over a thousand of these tubes on a 150,000 volt circuit simultaneously. The tubes are very long, but the tube is coiled in a close spiral, making a compact, brilliant lamp—of moderate candle power, of course. But with a score or two the room is bright. The efficiency of these lamps has not been determined very accurately, but it appears that about one watt

per foot of luminous material is the present consumption. High-tension engineers have a most interesting problem before them. Mr. Tesla is convinced the problem can and will be solved, and others in England seem likewise convinced.

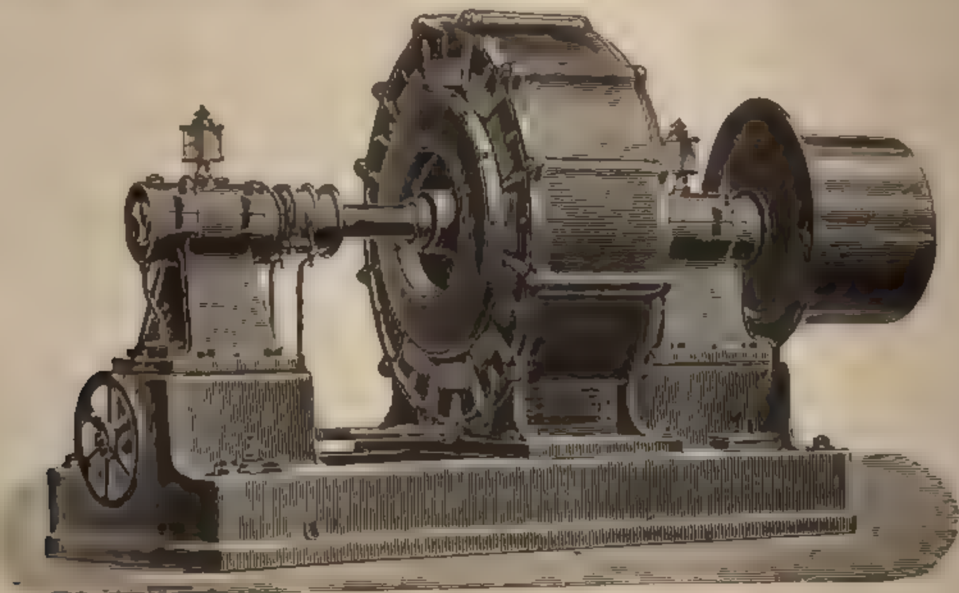
Catalogue.—Amongst the firms who have made themselves a name and a position in electrical circles, the Birmingham firm of Messrs. Fowler, Lancaster, and Co. are very noticeable. Commencing at the time of the first development of electric lighting in this country, they have gone steadily onward increasing their abilities of supply and the variety of their manufactures, until they may be said to occupy the position of principal electrical manufacture and supply company in the Midlands. Their first great hit was the china bases for electrical fittings, of which they were pioneers. To them is due the now almost universal screwed china covers; for it was not until after long experiments and insistance that the china makers would undertake to produce this class of goods with exactitude. Other branches have been added to the works—large and small orders are undertaken, from a complete installation downwards. The engineering of exhibitions, a most difficult thing to undertake well and quickly, has been carried out by them. The firm not long ago was converted into a limited company, and still grows. We have now received the catalogue of the company's manufactures and supplies—a really imposing book, plentifully and well illustrated, comprising electrical plant and fittings of every desirable kind from boiler down to pendants. Lancashire and Cornish boilers are shown in perspective section—a good idea for customers. Locomotive, water-tube, and other boilers are given, and then semi-portable engines, passing to horizontal and compound engines, with Richardson's electric governor and triple-expansion gear. High-speed direct-coupled engines and dynamos find a large place, as is right according to the best present practice, and gas engines, oil engines, and turbine, all find their place. The firm do not recommend any special dynamo, but along with their own do a good turn to every other first-class maker by recommending their products—high - and low, direct and alternating. Special attention, however, is given to electro-depositing machines, for which there is a great demand in Birmingham. The best show of their own manufactured goods is undoubtedly in the fittings, where some magnificent switchboards are shown, as designed for the Post Office, Birmingham, and elsewhere. Main switchboards for stations, house and charging switchboards are shown; switchboards for mixed arc and incandescent circuits, for electro-deposition and so forth, descending to branch and fuse boards. The various kinds of the switches and fuses shown are too numerous to mention in detail, but here the catalogue excels. We have double-pole, double-break, main, and branch switches of all kinds—strong contacts, and good electrical engineering design. Their patent "lever-bar" cut-out is one of the best and simplest. A bar with two contacts and a hook pivot carries the fuse; it is hooked on and pressed into place in an instant, and a spare fuse bar can always be kept hung up handy. Of decorated china switches there are a great number illustrated, and of ceiling roses the same. But the most noticeable feature, perhaps, is some 60 large pages filled with designs of ornamental fittings for electric light. A very large number of very handsome designs are here illustrated in a clear and effective manner. An immense amount of pains has evidently been taken with this catalogue, which ought to be inspected to be appreciated.

Islington.—The Islington Vestry, encouraged by the success of the St. Pancras central station, contemplate the establishment of their own central station for public and private supply on the same lines as at St. Pancras, and to this end they will apply to the Board of Trade for the necessary provisional order. A special committee appointed by the Vestry state in their report that in St. Pancras there is no likelihood of any charge being made upon the rates because of the public electric works, as the receipts will, upon the present basis of charge—6d. per unit—more than meet all expenses, including interest upon loans. Prof. Henry Robinson, electrical engineer to the St. Pancras Vestry, was consulted by the special committee, and in an elaborate report points out that Upper-street, Holloway-road, Seven Sisters-road, and other great thoroughfares in Islington "afford a most favourable field for the supply of electric light," and that "all experience proves that the requirements of such thoroughfares are so certain to result in remunerative business that no element of doubt or speculation is involved." Prof. Robinson shows that Islington can be supplied from two stations — one for the area to the north-west of the Great Northern Railway, and the other for the area to the south-east. These are estimated to cost, including sites and fittings, with engines, dynamos, and other electrical apparatus, but excluding mains, £50,000. About 5½ miles of mains could be laid for £35,000. Hence £85,000 altogether would be needed for two stations capable of supplying at the outset 12,000 lights of 16 c.p. (or 24,000 lights of 8 c.p.) in use at the same time, or equivalent current for motive and other purposes. One installation only would cost about £45,000. Prof. Robinson estimates that each of the stations he proposes would earn at least £9,000 per annum if the charge were 6d. per supply unit, but he points out that by charging a reduced rate to consumers who require the current for exceptionally long hours, the earning power of a station can be increased; and this policy induces people to use electricity for motive power, or for lighting basements during the day, thus employing the machinery when it would otherwise be idle. Hence St. Pancras Vestry has decided to charge 3d. per supply unit for current supplied during the day, while the charge for general purposes is 6d. If his plans be adopted, Prof. Robinson says: "No contribution from the rates would be involved, even during the initiation of the business, as the demand will grow with sufficient rapidity during the first year to enable the stations to not only pay their own way, but at the end of the year to be earning enough to make ample provision for the depreciation fund." Further, he shows that an equal illuminating power can be obtained from electricity as from gas at about the same cost as the latter is now charged in Islington. Finally, he remarks: "The current for public lighting can be produced at a very much lower rate than for private lighting, because the street lamps are required for about 3,800 hours per annum, and thus reduces the proportion which the fixed charges (on capital account) bear to the total cost of working. The effect of the reduction is to bring down the cost for public lighting to 2d. per unit, while the corresponding cost for private lighting is 4·8d. per unit. If a company supplied the current instead of the Vestry, the cost of street lighting would probably be doubled. Incandescent lighting in the streets cost about the same as gas lighting. Arc lamps are more suitable for street lighting than incandescent lamps, because they yield six or seven times as much light for the same expenditure of energy. The cost of lighting a street with arc lamps is greater than the cost of lighting it with gas, but if the comparison is made on the basis of light for light, the result comes out distinctly in favour of electricity."

ALTERNATE-CURRENT DYNAMOS.

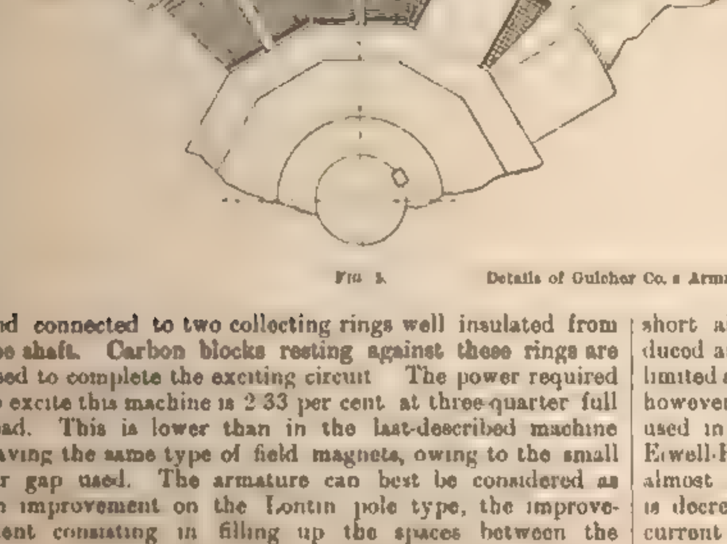
BY R. W. WEEKES, WHIT. SCH.

The Gulcher Company.—This company exhibited one of the Fricker alternators, used in this case for low-tension work. It is difficult to obtain an idea of the construction of the machine from the external view, but the sections this firm have kindly given me will make it clear. The field magnet details are somewhat similar in shape to those of the Elwell-Parker alternator, but there the similarity



The Gulcher Co.'s 30-Kilowatt Alternator.

ends. The magnets consists of a heavy star-shaped casting, having 12 radial arms in the machine exhibited. This casting is mounted on the spindle. The exciting coils are wound on bobbins made of sheet iron, with brass flanges, and the depth of winding increases with the radius, so as to get as much wire on as possible. The bobbins are slipped on and held in position by two iron bolts which screw into the hub, and are riveted into the upper flanges of the bobbin. These bolts take all the centrifugal strain, which tends to throw the bobbins off. The coils are all connected in series



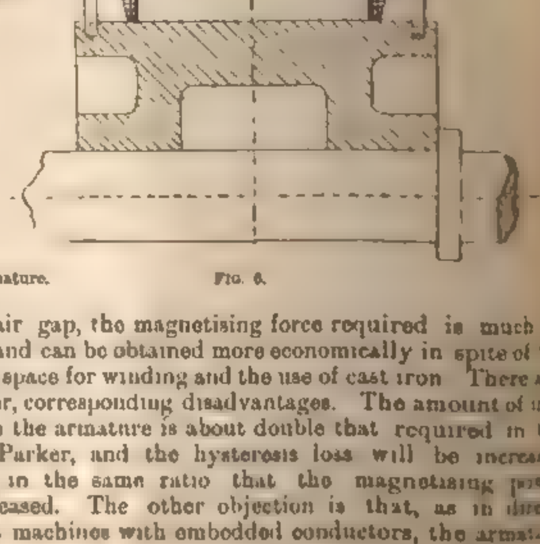


FIG. 5. Details of Gulcher Co.'s Armature. FIG. 6.

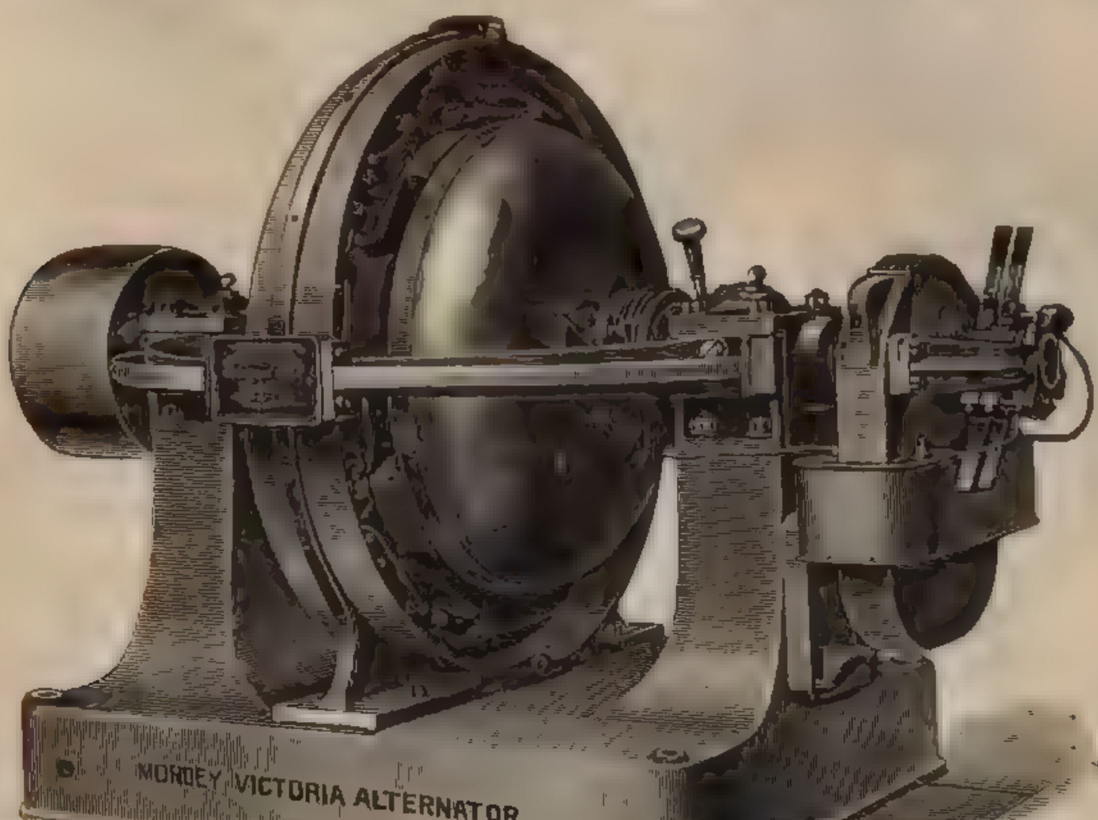
and connected to two collecting rings well insulated from the shaft. Carbon blocks resting against these rings are used to complete the exciting circuit. The power required to excite this machine is 2·33 per cent. at three-quarter full load. This is lower than in the last-described machine having the same type of field magnets, owing to the small air gap used. The armature can best be considered as an improvement on the Lontin pole type, the improvement consisting in filling up the spaces between the poles with iron, to prevent the variations of magnetic flux

In this machine, Figs. 5 and 6, the armature is built up of charcoal-iron plates ·016in. thick, placed radially, and so shaped that when completed they form a complete ring with 24 slots in it, into which the armature coils can be placed. These plates are clamped together in a frame by the bolts passing through the cast-iron end rings. The armature conductor used is copper strip ·162in. by ·08in., and 25½ turns of this are wound on edge on a former. When taken off, the coils are well baked and shellaced before being packed into the grooves in the iron. The insulation used between the core and the conductor is shellaced asbestos and fibre or a thin liner of teak. Thus, when completed, the coils are completely embedded in iron. The advantages of the construction in this type of dynamo are: First, the iron path in the armature offers nearly constant resistance wherever the poles may be, and hence there is little surging of magnetic lines. This does away with the necessity of laminated field magnets, such as are used in the ordinary Lontin type machine. Second, owing to the short air gap, the magnetising force required is much reduced and can be obtained more economically in spite of the limited space for winding and the use of cast iron. There are, however, corresponding disadvantages. The amount of iron used in the armature is about double that required in the Elwell-Parker, and the hysteresis loss will be increased almost in the same ratio that the magnetising power is decreased. The other objection is that, as in direct current machines with embedded conductors, the armature reaction is much increased owing to the small air gap.

Thus, when working, the exciting current will have to be varied considerably to prevent alteration in the potential differences at the terminals when the load is varied. Also with high voltages the insulation of the embedded coils would be a rather difficult matter. The armature coils were all connected in parallel when at the exhibition, and then gave 100 volts and 300 amperes. The advantage of using 25½ turns in each coil is that the half turn makes all the inside ends of the coil on one side of the armature, and all the outside ends at the other. Thus, when connecting in parallel, a simple ring of conductor is required to connect all the ends on one side together. The coils can, of course, be removed individually if one should become damaged, and to facilitate this the whole armature is placed on slides, and can in a short space of time be moved along parallel to the axis till clear of the armature field. A multiple threaded screw is used to obtain the necessary force, and at the same time a fairly rapid motion. The slots in the armature iron into which the coils are placed cause a slight variation of induction at the surface of the magnets. To prevent eddy currents in the iron, grooves of about $\frac{1}{16}$in. broad are turned in it ¼in. deep. The general construction of the bearings, etc., is well arranged, and the machine makes very little noise when working.

The following are the details of the 30-unit alternator made by this firm: Output, 100 volts 300 amperes at 700 revolutions; then it gives 70 complete periods per second; weight complete, 30cwt.; floor space, 4ft. 10in. by 3ft., height 4ft.; armature conductor, 08in. by ·162in., wound in 12 coils of 25½ turns each; weight of conductor, 39lb. 12oz.; magnets of cast iron, of 10in. by 5½in. section.

The Mordey Alternator.—This machine, although classed with those having fixed armatures and moving fields, differs in both principle and detail from any described above. In this alternator the direction of the lines of force through the armature coils is never reversed, as in all previously described machines, but the E.M.F. is produced by a variation of the magnetic field through the coil from the maximum to practically zero. This is done by having twice as many coils as there are poles. Then when one coil is directly opposite a pole, and hence has the maximum field throughout it, the adjacent coils are midway between two poles, and have practically no magnetic flux passing through them. The field magnet design for obtaining a number of consecutive poles of the same polarity is simple and easy to manufacture. The magnetic circuit consists practically of a short bar of cast iron excited by one large coil, and with inverted claw pole-pieces fastened on either end to form the returning path of the magnetic lines. In the alternator, the centre core, of cast iron, is keyed to the shaft, and the star-shaped end castings having the number of poles required are bolted against each face of this. The exciting coil is wound on a strong bobbin, which slips on the core. In the centre of the coil there is a space left in the winding to clear the armature coils. The advantage of thus causing the armature to project into the coil is that the magnetic circuit can be then shortened radially. The exciting current required is taken by two brass rings connected to the exciting coils, but the method of connecting to the revolving ring is better than the ordinary brush arrangement. It is done by means of a flexible band of copper gauze so folded as to give a rectangular section. The one end of the strip is secured to the terminal and the other has a weight attached. Thus, when hanging over the brass collecting ring, the weight gives the tension required to ensure perfect contact. The magnetic leakage with this type of field will be exceeding small, as the adjacent poles on each side of the armature have the same polarity. The armature coils are wound on cores of porcelain, which gives stiffness and good insulation without the disadvantages of the metallic core—*i.e.*, hysteresis or eddy currents. The conductor is a copper strip, which is wound bare with a strip of insulating material between each layer. The inside and outside ends respectively are connected by flexible conductors through the German-silver clamps, which hold the outer end of the coil. The bolts holding these plates of German silver on to the coil are all provided with spring washers, so that the grip on the porcelain is to a certain extent flexible. One side of the clamp is faced up in the lathe, so that when it is placed against the frame of the armature it ensures the coil being in a plane perpendicular to the axis. In the larger alternators



Mordey Victoria Alternator

the inside end of each armature coil has also a small brass clamp over the conductors to prevent any displacement of the individual strips taking place. The frame of the armature consists of a large ring usually cast in half and bolted together, Fig. 7. One radial face is machined in the lathe, and to this the coils are bolted. The bolt holes are elongated radially, so that the coils can be packed more tightly together after the working strain has compressed the various parts, and hence loosened them. The armature coils are connected half in series and the two halves in parallel to prevent a high potential difference between adjacent coils in all alternators having an output of about 50 kilowatts.

The mechanical details are well designed and carried out, the oil arrangements being automatic. Two small oil pumps are driven by belts off the main shaft, and ensure a good circulation of oil all the time the machine is at work.

Fig. 7.

The following are some particulars of the Mordey alternator recently shown at the Crystal Palace: The 100-kilowatt alternator gives 2,000 volts and 50 amperes at 430 revolutions. The weight complete is 9 tons 1cwt., and the floor space occupied is 8ft. 3¼in. by 6ft. 4¾in. The armature ring is 5ft. 10in. diameter and has 28 bobbins. There are 14 poles to each magnet casting, thus giving 100 complete periods per second. The magnets are 4ft. 8in. mean diameter, and the armature ring is 5ft. 10in.

The details of the weight are:

	tons	cwt.	qr.	lb.
Shaft	0	8	3	18
Bed-plate	2	10	2	0
Armature	0	10	1	12
Each magnet casting	1	16	2	0

The 50-kilowatt machine gives 2,000 volts and 25 amperes at a speed of 100; weight complete, 4 tons, floor space, 6ft. 7½in. by 5ft. 6¼in.; the armature ring has 20 bobbins, and is 4ft. 6in. diameter. The magnets are 3ft. 4½in. diameter, and each pole has 10 pole pieces.

Details of weight:

	tons	cwt.	qr.	lb.
Each pole	0	15	1	20
Magnet spool	0	13	1	22
Armature ring complete	0	6	0	20
Shaft	0	2	3	15

ELECTRIC RAILWAY MOTOR TESTS.*

BY PROF. GEO. D. SHEPARDSON AND EDWARD P. BURCH.

(Concluded from page 121.)

A large number of running tests were made on cars in regular service. Fig. 8 shows a run on the interurban line between Minneapolis and St. Paul. The distance is about 10 miles, the schedule time 55 minutes, cars equipped with two 25-h.p. single reduction motors. Special trains sometimes make this trip in 30 minutes or less. Fig. 9 shows three runs on the University line of Minneapolis on successive days, with the same car and same driver. The lower curve was taken when the rails were dry and dusty, middle curve with wet rails, and upper curve when the ground was covered with snow, 8in. deep on the level. The snow-plough had been over a part of the track about an hour before. The curves show variation of time, number of passengers being noted.

	Feb. 5.	Feb. 6.	Feb. 7.
Condition of track	Dry	Wet	Snowy
Number of stops	38	50	[illegible]
Average voltage	445	450	440
Average amperes	15·15	14·9	[illegible]
Average amperes while working	23·4	20·9	[illegible]

It will be noted that the current was less with wet rails although there were more passengers. The load at the station is about the same for a rainy day as for a dry, the difference being probably made up by the increased water on the lines and by the larger number of passengers on some cars.

Fig. 9 shows variation of current on a single car. Fig. 10 shows variation of current on a feeder to line with [illegible] cars, the average current being about 60 amperes. Fig. [illegible] is plotted from readings taken at intervals of two seconds. The ammeter stops some little time at the high and low points, showing that these are actual values of the current and not due to the inertia of the ammeter.

Fig. 11 gives the results of readings, one second apart, taken on the main ammeters in Minneapolis and St. Paul, and on one feeder in Minneapolis. There were about [illegible] cars on the Minneapolis line, 100 on St. Paul lines, and [illegible] on the one feeder.

Fig. 12 gives the daily load of the Minneapolis power house, the curves being plotted from readings of the ammeters taken at 10 minutes' intervals throughout the day. In this case the power units are unusually large, there being two triple-expansion condensing [illegible] engines, the constant loss from friction in engines, shafting and dynamos averaging 218 h.p. Indicator cards were taken simultaneously by means of electromagnetic attachments on each of the 12 indicators, the same current also giving signals to the observers at the ammeters.

A series of 13 tests were made for ascertaining the effect of wetting or greasing the rails on a curve. Two cars were coupled by a spring dynamometer and the pull noted while rounding the curve at ordinary speed, which was kept nearly uniform by means of a brake on the motor car. The average pull on the dynamometer is as follows:

	Dry.	Wet.	Greased.
Outer track	500-800lb.	400lb.	300[illegible]
Inner track	650lb.	400lb.	400[illegible]

The inner rail was wet or greased in each case, but on the inner track the greasing was not so thorough on account of the lateness of the hour. It is noticed that wetting the rail reduces the power required about one-third, and greasing reduces it one-half. Readings of the ammeters on the car correspond in general with the dynamometer readings.

The "bucking" of street-car motors is a subject of considerable interest to street railroad men, although it seems never to have been discussed in public. From the [illegible] of the books and papers, and from the ideas current among railroad employes, the conclusion is reached that little is known about its conditions, causes, or remedy. It is therefore thought wise to present the results of observations and tests, with a theory for the cause and remedy. It sometimes happens that an electric car suddenly stops and [illegible]

* Paper read before the American Institution of Electrical Engineers.

These buck worse when run on the "loop"—*i.e.*, with part of the field coils cut out, some of them bucking regularly

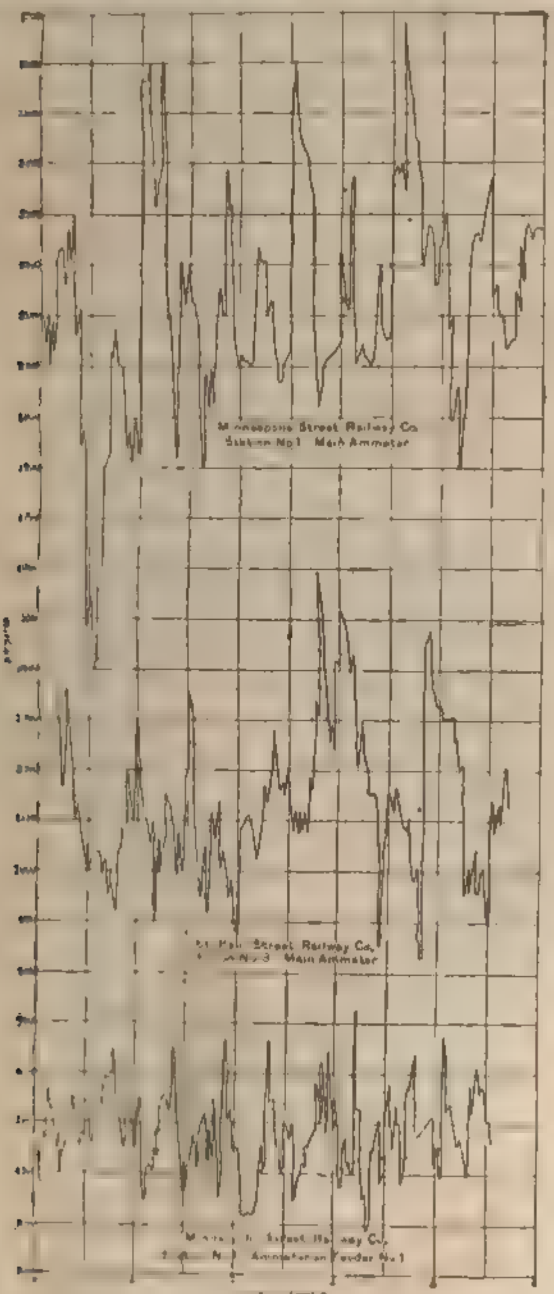

Fig. 11.

every time the loop is cut out. This is one reason why the use of the loop has been abandoned on this road except in a few cases. The machines with commutated fields would buck when the field coils became old, although they showed no signs of being grounded. Bucking became much less frequent when the commutated fields were replaced by a single pair of series coils.

It was noticed that bucking was very commonly preceded by flashing at the brushes, although flashing was not always followed by bucking.

The explanations offered are various. One is that the iron in the fields varies in magnetic quality, so that one motor works harder, and by some means acts upon the other as a dynamo. Another is that one motor becomes reversed while the other does not. Another is that bucking is caused by poor brushes or brushholders.

One explanation offered was that a partial break in the circuit, such as may be caused by shaking a loose connection, induces a high E.M.F. that causes a flash to span the commutator.

In searching for a reasonable explanation for all these cases in which no second ground connection existed, it was noticed in each case that bucking was more liable to occur when the field was comparatively weak; also where the armature reaction was greater. In each case the neutral line is shifted, and the coils under the brushes are in an active field. The large current in short-circuited coils further distorts the field, and the sparking at the brushes becomes excessive, causing a vigorous flashing. As soon as the counter E.M.F. in the sections leaving the brushes rises above 20 volts, the arc is carried around from one brush to the other, thus grounding the positive brush and short-circuiting the armature, which then acts as a dynamo and causes the motor to buck. Such bucking is usually less vigorous than when caused by a dead ground, on account of the resistance of the arc. This explanation covers all the cases noted.

Such being the causes of bucking, the remedies are plain. Armature reaction must be reduced. This militates against the conclusion drawn by Mr Parshall in his recent Institute paper, that the strength of field is of little importance, and that the windings of the armature should be a maximum. The liability to bucking would be reduced even when there is a large armature reaction, if the armature is divided into a large number of sections.

An obvious remedy for bucking caused by direct grounding would be to connect the fields between armature and ground instead of between armature and trolley. With such an arrangement, a ground on the fields would simply cut out a part of the coils, and cause that machine to work harder. A ground at brush between armature and field would cause a sudden forward impulse on account of the field requiring some time to lose its magnetism, and would blow the fuse. A ground on armature would likewise cause a sudden forward impulse and blow the fuse. With such an arrangement there would be no true bucking except in case of the flashing as noted. An incidental advantage

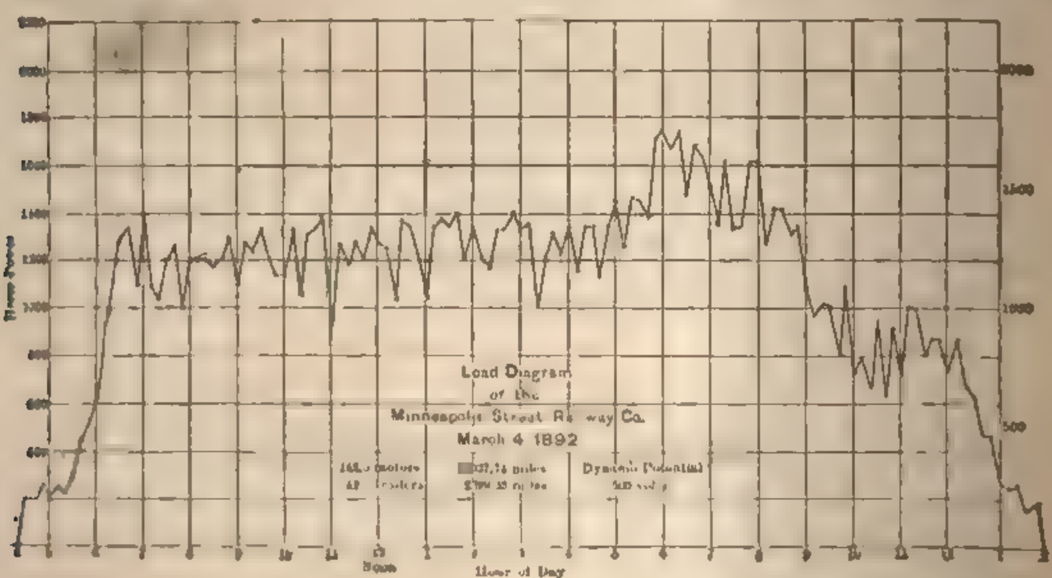

Fig. 12.

of this arrangement is that the difference of potential between the field and the frame of the machine is reduced to a few volts caused by the drop through the field; hence there is less danger of grounding the field. The increased difference of potential between armature and core is only a few volts, and would not affect the insulation very much.

TRANSFORMERS.

One objection to the Ferranti type of transformer seems to be the trouble of a repair when a burn-out occurs. In this class of transformer the iron is placed in bands, which are bent over, and these in case of repair have to be bent back by main force, the coils repaired, and the whole replaced in original position, the process often taking a day or more. If the coils could be slipped out easily and fresh coils put on, a transformer need take only 10 minutes or so to repair. We have lately seen an improved arrangement of this nature, which seems to have much to recommend it. The thin iron plates are made in square horse-shoe shape, with two legs; these plates overlapping alternately, form a square core with hollow centre, in which the coils can just be placed. The plates are arranged radially round a centre, giving space for air ventilation or circulation of oil. To repair, the binding wire is cut, and the top halves of the plates are lifted off, leaving the coil free of access. The plates can be slipped back and refastened, the whole operation being simple and easy for an ordinary workmen, and taking very little time. As the use of transformers extend, these practical points will become quite as important as comparative efficiency.

ABERDEEN.

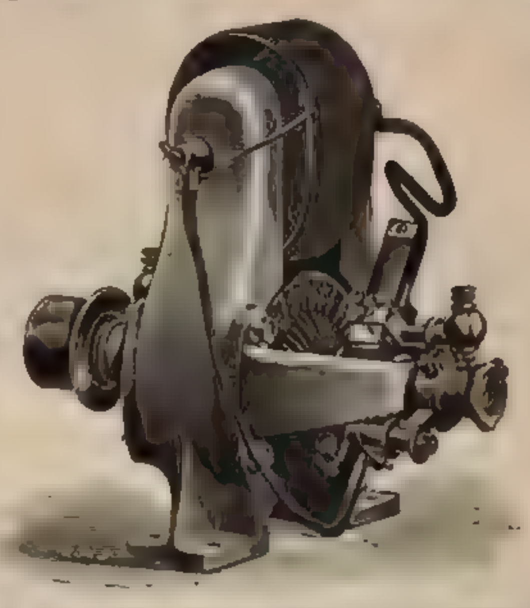
Acting on the report by Prof. Kennedy, the Gas Committee of the Aberdeen Town Council on Tuesday resolved, on the casting vote of Bailie M'Kenzie, the convener, to adopt an instalment of electric lighting for public and other buildings in the city. The amendment to the resolution demanded delay until it was ascertained how many persons were likely to use the light. As Prof. Kennedy understood that the Council do not at present contemplate doing anything in the direction of public lighting of the streets he confined himself in his report to the best method of supplying the electric light to shops, offices, and public and private buildings. It is in the area, described as the eastern district, in which he considers operations should be commenced. Dealing with the probable demand for light, he says it might be taken that the electric light in a private house would cost 25 per cent. more than for gas, and in a shop or club 75 per cent. more. He started on the assumption that the income per foot of street frontage would be about one-fifth of that derived at present from the sale of gas along the same frontage, and on that estimate about 10,000 lamps of 8 c.p. would be installed, of which about 7,000 would be in the eastern and 3,000 in the western district—a number that ought to be installed within two or three years' time. The site recommended for the central station is one adjoining the gas works at Cotton-street. As to the system to be adopted, Prof. Kennedy considers that the conditions existing in Aberdeen point distinctly to the use of batteries which can be charged during a few hours out of the 24, and can then supply a current during the long light hours without the necessity of running boilers or engines for the purpose.

Four different systems are described in detail which are reasonably possible in the case of Aberdeen. The first of these is one in which a high-pressure alternating current may be used, but while in capital cost this system would be least expensive for Aberdeen, it would render necessary the continual running of machinery in the station day and night. The second system mentioned is one of using a limited number of large transformers in sub-stations, and the third, the system in use in London and Oxford, by which a continuous current is transmitted from a central station at high pressure through feeders to a number of sub-stations, in each of which it is transformed down by a "dynamotor" to a low tension and then distributed to the consumers' premises through ordinary low-tension network. The fourth is the direct system with batteries. There would be no difficulty in supplying the eastern district on an ordinary direct-current system, used with battery at the Cotton-street station, so that there would be no [illegible]t, machinery, or apparatus of any kind outside the central station itself. According to this plan, there would be the advantage of having only a single system in the station, of having a reduced amount of copper in the long-distance feeders, and of being able to shut down the station and run off batteries at low loads and during daylight hours. The use of the continuous current would also allow them to supply currents for power—*i.e.*, for driving of motors of any kind if it should be required. The mains, it is proposed, should be laid underground. To run the works economically, he recommends to be put down at the station five dynamos, having a capacity of about 260 e.h.p. for the eastern district, each dynamo to be driven by its own engine. Under the system which he advised them to adopt, the price, including batteries, would be £19,900 and £30,600—the former for the eastern district alone, and the larger sum for the two districts together. As to income, it is estimated at 9s. per annum per lamp installed, or £4,500 by the time they had the equivalent of 10,000 lamps on current. Prof. Kennedy estimates that the additional cost in fuel, stores, and wages of working a high-tension alternating current system, as compared with that which he recommended, would not be less than £500 per annum. As the saving in first cost would only be about £3,300, the balance of economy remained in favour of the system he recommended.

TRADE NOTES AND NOVELTIES.

Small Electric Motors.

The "S.M." electric motor has been designed to meet a considerable want in connection with electric supply companies for a really useful small motor. Hitherto small motors have been little better than toys, and not suitable for commercial use. The "S.M." electric motors, however, placed upon the market by Messrs. Ernest Scott and Mountain, Limited, of Newcastle-on-Tyne, are made upon lines dictated by long practice in the designing of dynamos and motors of large capacity, and whilst of small size, embody all the special features in engineering and electrical design necessary to ensure satisfactory working.



These motors will be found of great value for driving small workshops, lathes, machinery, fans, sewing machines, and for many other purposes where small powers are required and electric current is available. In private houses and mansions, where electric light is installed, they will be found extremely useful for driving fans for ventilation, pumps for the house supply of water, churns or butter-making machinery, saws for cutting firewood, boot-blacking, and other household purposes for which electricity might be used.

The "S.M." electric motor is made in four standard sizes, and in ordering it is only necessary to state the E.M.F. of the current and purpose for which it is required. The motors are made in four sizes: ¼ h.p., ½ h.p., ¾ h.p., and 1 h.p. effective. They are made to run at speeds of about 1,500 or 2,000 revolutions, but can be wound to lower speeds if required, to suit requirements.

Electric Lock.—An ingenious application of well known principles to an electric lock allows any door or gate to which it is attached to be either unlocked and left in this condition, or permanently locked from any desired point.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Prof. D. E. Hughes, Mr. Shelford Bidwell, Prof. J. A. Ewing, Mr. W. C. Johnson,** and **Mr. A. A. Campbell Swinton.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

THE BRITISH ASSOCIATION.

On Wednesday last the fifty-ninth meeting of the British Association met at Edinburgh, under the presidency of Sir Archibald Geikie. This is the fourth time that the association has met in the capital of Scotland—its fourth meeting in 1834, its twentieth in 1850, its forty-first in 1871, were the previous meetings. Since the first Edinburgh meeting the whole of the applications of electricity now utilised by the world have germinated and fructified. In 1834 telegraphy was in the unknown, telephony was not foreshadowed. True, the dynamo was born, but no use had been found for it, nor was the apparatus looked upon as much more than a laboratory toy. Electro-deposition was of later date, as, of course, were electric lighting and transmission of power. According to our views the world has moved very fast in the half century that has since passed, but we are probably as much in the dark now as to what will be common property to the world of 1950, as were the good people who met in Edinburgh in 1834 to what is common property now. The carping critic might well ask what part has the British Association played in this march of electrical progress. The answer ought to be instantaneous, that the existing system of measurement is due to the work of the association. We may not be altogether enamoured of the system as applied to engineering work, but undoubtedly the consolidating and experimental work under the auspices of the British Association, so far as units and measurement are concerned, has proved of incalculable value. It may be doubted if the modern methods of sectional discussion are likely to lead to anything valuable. Long-winded speeches are made with no real objective. A does not agree with B, and C does not agree with either. Still, the bringing out of divergent opinions may lead to definite agreement at no very distant day. There will be some one or other direction toward which men's minds will tend, and in this direction something satisfactory may ultimately be obtained. As year after year passes we are becoming more and more dissatisfied with the work of the sections. The papers obtained are many of them not fit for discussion. Many are preliminary observations with promises of future performances, which further investigations relegate to the Greek kalends. It is something approaching to a disgrace for a so-called scientific assembly to admit many of these papers, but no doubt there is another side to the question. If we are bold and blunt enough, we shall admit as at present conducted the British Association is but a huge scientific picnic, the papers and sectional meetings being but a framework to hang a number of other meetings upon, at which scientific conversation does more to make friends acquainted with the work and progress of the past year than anything else at the meeting. Were it not for these social gatherings, the presidential addresses, and the reports of committees, the British Association would soon die of inanition. Of course there are good papers among the rubbish—sufficient, perhaps, as things go, to leaven the mass and make the sectional proceedings acceptable. It is unfortu-

nate that the mass of younger contributors are permitted to add so much immature and speculative matter to the proceedings. Another important want is a kind of unbiassed judge who will undertake the somewhat onerous task of sifting the wheat out of the set discussions, and presenting it as simply and baldly as possible to the eyes and ears of those to whom the scientific verbose jargon is a dead language. Who now knows the conclusions, if any, upon which the disputants are agreed? The summing up of a judge is sadly needed. With regard to the discussions on papers read in the sections, the secretaries are apt to provide too many papers, and thus sometimes to burke an interesting discussion, though usually the discussion is merely formal. This defect would easily be met by weeding out the objectionable papers. It may, however, happen that all these remarks are out of date; that fewer and better papers will be before the sections at Edinburgh; that greater care will be taken to make clear the points under discussion; and that at the end of the meeting we shall have to acknowledge that the British Association, although approaching its sixtieth anniversary, is by no means played out as a leading institution in the realms of science. Let us hope the meeting at the modern Athens will be without the bad features of some of its predecesors and superabundant of all their good features.

OUR PORTRAITS.

Hughes, Prof. David Edward, F.R.S., was born in London in 1831; his parents, however, emigrated soon after to the United States. He was in 1850 (on account of his musical talents) appointed professor of music at the College of Bardstown, in Kentucky. His equal talents for physical sciences later on procured him the appointment to the Chair of Natural Philosphy at the same college. His first great invention was that of the printing telegraph which bears his name. In 1855 he took out his first patent for this instrument, which he sold the next year to the American Telegraph Company, of New York, who soon after amalgamated with several other telegraph companies owning the Morse patent, forming the present Western Union Telegraph Company. In 1857 Prof. Hughes visited Europe in order to try and get his instrument tried upon the lines of the Electric Company, but in this he did not succeed until 1863, when the patent was purchased and the instrument used by the United Kingdom Electric Telegraph Company, of London. In 1859 he invented and patented an oil cable for submarine and subterranean electric wires, in which the principle of the self-restorative powers of rosin oil, together with its high insulation, was used for this purpose. From 1857 to 1860 Prof Hughes tried in vain to get either his instrument or his fluid cable adopted in practice. He then went to France, where the printing telegraph was at once placed in actual service between Paris and Lyons, and after one year's continued working the system was finally adopted for all the important lines of France. Prof. Hughes was then decorated with the Order of the Legion d'Honneur, of which order he was made Chevalier, and also nominated a member of the Commission de Perfectionnements At the end of 1862 the Italian Government invited Prof. Hughes to visit Italy and instruct their officers in the use of his instrument, where, after a practical trial of six months, his instrument was finally adopted for the station lines. In 1863 the instrument was adopted by the United Kingdom Company, and in 1870 by the Submarine Telegraph Company, who were all merged into the present Government postal department. In England, the instrument is now used between London and all the large foreign capitals for their continental traffic. It is also used by the *Times*, *Daily Telegraph*, *Daily News*, etc, for their foreign telegrams. In 1864 Prof. Hughes visited Russia, where the system was also adopted for their line. Between 1864 and 1876 this instrument was successively adopted by Germany, Austria, Turkey, Holland, Switzerland, and Spain, and in every country up to this date the use of the instrument has been of a progressive and increasing nature. In 1878 Prof. Hughes announced through a paper to the Royal Society his discovery of the microphone, which is now universally employed as the transmitter to the telephone. In 1879 he presented to the Royal Society his invention of the "induction balance," now well known by the scientific world. In 1880 he was elected a Fellow of the Royal Society, and in different years, and by different Governments, he has received the high decorations of Commander Legion d'Honneur (France), Charles III. (Spain), Iron Crown (Austria), Medjedieh (Turkey), and Knight of St. Anne (Russia), St. Maurice and St. Lazarus (Italy), St. Michael's (Bavaria), and he received the special gold "Grand Prix" (one of ten only) Paris Exhibition, 1867, as well as the Grand Diplome d'Honneur, Paris, Diplome d'Honneur, Paris Electrical Exhibition, 1881, besides numerous other medals, such as Royal gold medal of the Royal Society, etc. In 1886 he was elected president of the Institution of Electrical Engineers. He is now a member of numerous committees, and also one of the managers and vice-president of the Royal Institution of Great Britain. Thus far we follow the biographical notice from "Men and Women of the Times," but it is well known that we are inclined to look upon Prof. Hughes as one of the modern heroes of science, whose example may be followed by those of the younger generation who aspire to "leave footprints on the sands of time."

Ewing, James Alfred, was born at Dundee in 1855, and after schooling there went on to Edinburgh University, where he developed his taste for engineering under Fleeming Jenkin, and for physics under Prof. Tait. Entering the service of Thomson and Jenkin, he received a practical training in telegraph engineering, at a time when it was still true that the testing room of the cable factory was the best laboratory in which an electrician could be trained. He took part in the laying of the Western and Brazilian and other cables, and assisted in the development of several of the chiefs' electrical inventions. In 1878 he was appointed Professor of Engineering in the University of Tokyo, Japan—a post which he held for five years, resigning it in 1883 to become professor of the same subject in the college then newly founded in his native town. In Japan, and again in Dundee, he devoted much time to electrical work, beginning while at Tokyo the experiments in magnetism with which his name is specially connected. A little more than a year ago he received the appointment of Professor of Mechanism and Applied Mechanics in the University of Cambridge, where he is now throwing himself into the work of establishing a laboratory and building up an engineering school. Prof Ewing is the author of many papers on engineering subjects, but to electrical engineers his best known writings are the papers in the *Philosophical Transactions* and elsewhere, which contain the results of his magnetic investigations. His theory of molecular magnetism became generally known at the British Association meeting of 1890, when he showed a model exhibiting the process of magnetisation. His treatise on "Magnetic Induction in Iron and other Metals," published in the beginning of the present year, gives an account of his own researches as well as the work of others, and brings the subject up to date. At the meeting of the British Association now being held in Edinburgh, Prof. Ewing will read a paper which we make bold to say will prove the most practically important read at this meeting. Prof. Ewing is a member of the chief engineering institutions, as well as a Fellow of the Royal Society; he is a B.Sc. of Edinburgh, and an M.A. of Cambridge.

Bidwell, Shelford, M.A., LL.B., F.R.S., M.I.E.E. Born March 6, 1848. Educated privately and at Caius College, Cambridge. Graduated B.A. (mathematical tripos) in 1870, LL.B. (law tripos) in 1871, and M.A. in 1873;

called to the Bar (Lincoln's Inn) in 1874. He has devoted much time to experimental scientific work, especially in connection with electricity and magnetism. Accounts of his researches are contained in numerous papers published in the *Philosophical Transactions* and the *Proceedings* of the Royal Society, the *Proceedings* of the Physical Society, the *Journal* of the Institution of Electrical Engineers, the *Philosophical Magazine*, *Nature*, and other scientific periodicals. Among the most important of his investigations are those relating to the magnetisation of iron in strong fields, to the changes of length which bars of iron, nickel, and cobalt undergo when magnetised, and to the electrical behaviour of selenium under the influence of light. He has delivered many lectures upon scientific subjects in London and elsewhere, and has several times had the honour of addressing audiences at the Royal and London Institutions. Has served upon the Councils of the Institution of Electrical Engineers (then the Society of Telegraph Engineers) and the Physical Society, of which latter he was for some years a vice-president. He was elected a Fellow of the Royal Society in 1886. He was an original director of the old Edison Electric Light Company, and when that company was amalgamated with the Swan, was invited to a seat on the board of the Edison-Swan United Company, a post which he still holds.

Johnson, W. Claude, M.I.C.E., at the age of seventeen was articled to Mr. W. F. Gooch, C.E., serving five years' apprenticeship in the locomotive works of the Vulcan Foundry, after which he studied at King's College, London. From 1869 to 1875 he was with the Telegraph Construction and Maintenance Company, and acted in various capacities both at the works and in cable-laying expeditions. Here he became thoroughly conversant with the requirements of cable laying and picking up; indeed, so close was his study of the subject that he soon became recognised as the leading authority dealing with such apparatus. Hence, when in 1875 he joined Mr. S. E. Phillips, to form the firm of Johnson and Phillips, that firm took a commanding position in the manufacture of all cable apparatus, and from that time to this the firm has probably designed, or, we should say, Mr. Claude Johnson has designed, and the firm constructed, the largest part of the cable machinery existing. Mr. Claude Johnson controls Charlton Works, which have steadily increased in size, and are still being added to. These works now cover an area of seven acres, and employ about 500 men. Latterly, the developments of electric lighting have overshadowed those of cable work, and the larger part of the works is devoted to lighting requirements, although just at present they are busy with cable machines designed for M. Grammont's factory in France, and other work for the Eastern Telegraph Company. It speaks much for the capacity of Mr. Claude Johnson as an engineer and as an organiser to see the admirable way in which these works are conducted. He has had the great advantage of being well supported by his scientific partner, Mr. S. E. Phillips. Literary and professional men are generally supposed to owe much to having sat at the feet of some Gamaliel, till it seems a pity that it was not fashionable for a successful business man to be surrounded with a bevy of learners. Of this firm it might be said that it pursues the only true course to ensure permanent success: it undertakes nothing it cannot perform, and is satisfied with none but the very best workmanship and materials. This speaks volumes for the heads and hearts that guide the venture.

Swinton, A. A. Campbell, was born in Edinburgh in 1863, and became in 1882 a pupil to Messrs. Sir W. G. Armstrong, Mitchell, and Co., at their Elswick works. In 1884 he succeeded to the position of electrical engineer to the company, and in this capacity carried out the electric lighting of all the war vessels built at Elswick up to 1887. During this period he introduced the system of wiring ships with lead-coated cable, since adopted by the English Admiralty, the first vessel to be wired exclusively on this principle being the Japanese cruiser "Naniwa Kan." In 1887 Mr. Swinton left Newcastle to take up his residence in London, retaining, however, the appointment of electrical adviser to Messrs. Armstrong, which he still holds. Since that date numerous electric light installations have been installed under his superintendence, among the more important of which may be mentioned those at New Scotland Yard for the Metropolitan Police, where there are nearly 1,200 lights; at Lambton Castle, for the Earl of Durham; at Wynyard Park, for the Marquis of Londonderry; at Sunningdale Park, for Major W. J. Joicey; at Hatchlands, for Mr. Stuart Rendle, M.P.; and at Moy Hall, for the Mackintosh of Mackintosh. He is also, by appointment of the Secretary of State, consulting electrical engineer to the Metropolitan Police, and has taken some part in connection with the reorganised New Telephone Company recently brought out by Messrs. Rothschild. Besides being the author of a number of articles on scientific subjects in the daily and periodic press, Mr. Swinton has written two books on electric lighting—"The Principles and Practice of Electric Lighting," published in 1884, and "The Elementary Principles of Electric Lighting," first published in 1886, which has run to two editions. He also exhibited a number of curious photographs of electric discharges at the last *conversazione* of the Royal Society, and is reading a paper on the subject of these photographs at the Edinburgh meeting of the British Association. Mr. Swinton, who is an associate member of the Institution of Civil Engineers, and a member of the Institution of Electrical Engineers, is also London representative of Messrs. C. A. Parsons and Co., of Newcastle-on-Tyne, manufacturers of the Hon. Charles Parsons's well-known steam turbines. Mr. Swinton has patented several improved forms of magneto-bell and telephone apparatus.

THE BRITISH ASSOCIATION.

The fifty-ninth meeting of the British Association was inaugurated at Edinburgh on Wednesday last by the presidential address of Sir Archibald Geikie. Although this address is of an exceedingly interesting character, it deals almost exclusively with geological questions, which are altogether outside the sphere of our labours. Sir Archibald Geikie called attention to a remarkable group of men who a century ago were discussing the great problem of the history of the earth, amongst whom James Hutton stands conspicuously. His famous theory of the earth was perhaps the germ of all modern views in that direction, and it was with the Hutton theory that the presidential address dealt. Those of our readers who are interested in the subject will no doubt be able to read this address elsewhere.

More closely connected with the subject which it is our special province to discuss are the presidential addresses in the Physical Section and in the Mechanical Section, or as they are known to the *habitués* of the association, Section A and Section G. These addresses were delivered by the respective presidents on Thursday as follows:

Address to the Mathematical and Physical Section

BY PROF. ARTHUR SCHUSTER, PH.D., F.R.S., F.R.A.S., PRESIDENT OF THE SECTION.

In opening the proceedings of our annual meeting the temptation is great to look back on the year which has passed and to select for special consideration such work published during its course as may seem to be of the greatest importance. I fear, however, that a year is too short a time to allow us to form a fair estimate of the value of a scientific investigation. The mushroom, which shoots up quickly, only to disappear again, impresses us more than the slow growing seedling which will live to be a tree, and it is difficult to recognise the scientific fungus in its early stage. But, although I do not feel competent to give you a review of the progress made in our subject during the last 12 months, there is one event to which some allusion should be made. It has been the sad duty of many of my predecessors to announce the death of successful workers in the field of science, but I believe I am unique in having the pleasure of recording the birth of a scientific man. At the beginning of this year there came into the world a being so [illegible] that he could, without preparation, take up the work of the most eminent man amongst us. Believers in the transmigration of souls have speculated on the fact that Galileo's death and Newton's birth fell within a year of each other; but no event has ever happened so striking as that which took place on the 1st of January, when the mantle of Sir William Thomson fell on the infant Lord Kelvin. Those who have attended these meetings will feel with me that the honour done to our foremost representative, an honour which has been a source of pride and satisfaction

to every student of science, could not altogether remain unnoticed in the section which owes him so much.

We are chiefly concerned here with the increase of scientific knowledge, and we derive pleasure in contrasting the minor state of ignorance of our own time with that which prevailed a hundred years ago. But when we contrast at the same time the refined opportunities of a modern research laboratory with the crude conditions under which the experimentalist had to work at the beginning of the century, we may fairly ask ourselves whether it is possible by means of any systematic course of study or by means of any organisation to accelerate our progress into the dark continent of science. A number of serious considerations arise in connection with this subject, and though I am not going to weary you by attempting an exhaustive discussion, I should like to draw your attention to a few matters which seem to me to be well worthy of the consideration of this association. Changes are constantly made and proposed in our existing institutions, or new ones are suggested which are to serve the purpose of a more rapid accumulation of knowledge. I need only allude to the alterations in the curriculum of the science schools in our old universities, made partly for the purpose of fitting their graduates for the conduct of original research, or to the national laboratory proposed by my predecessor in this chair for carrying out a certain kind of scientific investigation which at present is left undone, or is done by private enterprise. Even our own association has not escaped the evil eye of the reformer, and, like other institutions, it may be capable of improvement. But in choosing the direction in which a change may best be made, I think we may learn something from the way in which Nature improves its organisms. We are taught by biologists that natural selection acts by developing those qualities which enable each species best to survive the struggle for existence. Useless organs die off or become rudimentary. Nature teaches us, therefore, how a beautiful complex of beings, mutually dependent on each other, is formed by improving those parts which are best and most useful and letting the rest take care of itself. But in many of the changes which have been made or are proposed, the process of reform is very different. The weakest points are selected, our attention is drawn to some failure or something in which we are excelled by other nations, and attempts are made to cure what perhaps had better be left to become rudimentary. The proceeding is not objectionable as long as the nourishment which is applied to develop the weaker organs is not taken from those parts which we should specially take care to preserve. To apply these reflections to the question with which we are specially concerned, I should like to see it more generally recognised that although there is no struggle for existence between different nations, yet each nation, owing to a number of circumstances, possesses its own peculiarities, which render it better fitted than its neighbours to do some particular part of the work on which the progress of science depends. No country, for instance, has rivalled France in the domain of accurate measurement, with which the names of Regnault and Amagat are associated, and the International Bureau of Weights and Measures has its fitting home in Paris.* The best work of the German universities seems to me to consist in the following up of some theory to its logical conclusions and submitting it to the test of experiment. I doubt whether the efforts to transplant the research work of German universities into this country will prove successful. Does it not seem well to let each country take that share of work for which the natural growth of its character and its educational establishment best adapt it? Is it wise to remedy some weak point, to fill up undoubted gaps, if the soil that fills the gaps has to be taken from the hills and elevations which rise above the surrounding level?

As far as the work of this section is concerned, the strongest domain of this country has been that of mathematical physics. But it is not to this that I wish specially to refer. Look at the work done in Great Britain during the last two centuries; the work not only in physics, but in astronomy, chemistry, biology. Is it not true that the one distinctive feature which separates this from all other countries in the world is the prominent part played by the scientific amateur, and is it not also true that our modern system of education tends to destroy the amateur? By amateur, I do not necessarily mean a man who has other occupations and only takes up science in his leisure hours, but rather one who has had no academical training, at any rate in that branch of knowledge which he finally selects for study. He has probably been brought up for some profession unconnected with science, and only begins his study when his mind is sufficiently developed to form an entirely unbiassed opinion. We may, perhaps, best define an amateur as one who learns his science as he wants it and when he wants it. I should call Faraday an amateur. He would have been impossible in another country; perhaps he would be impossible in the days of the Science and Art Department. Other names will occur to you, the most typical and eminent being that of Joule. It is not my purpose to discuss why distinguished amateurs have been so numerous in this country, but I am anxious to point out that we are in danger of losing one great and necessary factor in the origination of scientific ideas.

One of the distinctive features of an amateur is this, that he carries not the weight of theories, often not the weight of knowledge, and, if I am right, there is a distinct advantage in having one section of scientific men beginning their work untrammelled by preconceived notions, which a systematic training in science is bound to instil. Whatever is taught in early age must necessarily be taught in a more or less dogmatic manner, and in whatever way it is taught, experience shows that it is nearly always received in a dogmatic spirit. It seems important, therefore, to confine the early training to those subjects in which preconceived notions are considered an advantage. It is to me an uncongenial task to sound a note of warning to our old universities, for the chief difficulties in which they are placed at present are due to the fact that they have given way too much to outside advice; but I cannot help expressing a strong conviction that their highly specialised entrance examinations are a curse to all sound school education, and will prove a still more fatal curse to what concerns us most nearly, the progress of scientific knowledge. If school examinations could be more general, if scientific theories could only be taught at an age when a man is able to form an independent judgment, there might be some hope of retaining that originality of ideas which has been a distinctive feature of this country, and enabled our amateurs to hold a prominent position in the history of science. At present a knowledge of scientific theories seems to me to kill all knowledge of scientific facts. It is by no means true that a complete knowledge of everything that has a bearing on a particular subject is always necessary to success in an original investigation. In many cases such knowledge is essential, in others it is a hindrance. Different types of men incline to different types of research, and it is well to preserve the dual struggle. The engine which works out the great problem of Nature may be likened to a thermo-dynamic machine. The amateur supplies the steam and the universities supply the cold water; the former, boiling over often with ill-considered and fanciful ideas, does not like the icy douche, and the professional scientist does not like the latent heat of the condensing steam, but nevertheless the hotter the steam and the colder the water the better works the machine. Sometimes it happens that boiler and cooler are both contained in the same brain, and each country can boast of a few such in a century, but most of us have to remain satisfied with forming only an incomplete part of the engine of research. But while it is necessary to recognise the great work done by the unprofessional scientists, it seems not untimely to draw their attention to the damage done to themselves if they overstep their legitimate boundaries, and especially if they seek popular support for their theories, which have not received the approval of those who are competent to judge. An appeal from Alexander sober to Alexander drunk will not prove successful in the end. The gradual disappearance of the amateur may be a necessary consequence of our increased educational facilities, and we must enquire whether any marked advantages are offered to us in exchange. There is one direction in which it would seem at first sight, at any rate, that a proper course of study could do much to facilitate the progress of research.

On another occasion I pointed out that two parties are necessary for every advance in science—the one that makes it, and the one that believes in it. If the discoverer is born, and cannot be made, would it not be possible at any rate to train the judgment of our students so that they may form a sound opinion on the new theories and ideas which are presented to them? It is too early as yet to judge in how far our generation is better in this respect than the one that has gone before them, but on closer examination it does not seem to me to be obvious that any marked improvement is possible. Every new idea revolutionising our opinions on some important question must necessarily take time before it takes a proper hold on the scientific world. Is it not true that anyone who can at once see the full importance of a new theory, and accept it in place of the one in which he has been brought up, must stand at a height almost equal to that of the originator? The more startling and fresh the new conception, the fewer must be those who are ready to adopt it. But looking back at the history of science during the present century, is there much evidence that great discoveries have been seriously delayed by want of proper appreciation? We may hear of cases where important papers have been rejected by scientific societies, and occasionally a man of novel ideas may have been too much neglected by his contemporaries. I doubt whether such cases of apparent injustice can ever be avoided, and simply looking back on the great changes involved in matters of primary importance, such as the undulatory theory of light, the conservation of energy, and the second law of thermo-dynamics, I cannot admit that there is much reason to be dissatisfied with the rate at which new theories have been received. Those who experience a temporary check, owing to the fact that public opinion is not ripe for their ideas, are often amply rewarded after the lapse of a few years. The disappointment which Joule may have felt during the time his views met with adverse criticism from the official world of science was no doubt amply compensated by the pleasure with which he watched the subsequent progress of research in the new domain which his discoveries have opened out. The point is not one of academic interest only, for the fear of repressing some important new discovery has a detrimental influence in another direction. The judgment of the scientific world seems to me to be tending too much towards leniency to apparently absurd theories, because there is a remote chance that they may contain some germ of real value. A new truth will not be found to suffer ultimately by adverse and even unreasonable criticism, while bad theories and bad reasoning, supported by the benevolent neutrality of those to whose judgment the scientific world looks for guidance, are harmful in many ways. They block the way to an independent advance and encourage hasty and ill-considered generalisations. The conclusion I should draw from the considerations I have placed before you are these. I believe that a reasonable censorship exercised by

* Much of the good work done by this bureau remains unknown, owing to the miserly way in which their publications are circulated. No copies are supplied even to the university libraries. The explanation, of course, is "want of funds." In other words, England, France, and Germany, together with other nations, unite to do a certain kind of work, but cannot afford to distribute a few copies of the publication to the public for whose benefit the work is undertaken.

our scientific societies is good and necessary; that those whose fate it is to be called on to express an opinion on some work or theory should do so fearlessly according to their best judgment. Their opinion may be warped by prejudice, but I think it is better that they should incur the risk of being ultimately found to be wrong than that they should help in the propagation of bad reasoning. There is one matter, however, on which all opinions must agree. Worse than bad theory or logic is bad experimental work. Should we then not rigorously preserve any influence or incentive which encourages the beginner to avoid carelessness and to consider neither time nor trouble to secure accuracy? There is no doubt to my mind that the prospect of admission to the Royal Society has been most beneficial in this respect, and that the honourable ambition to see his paper published in the *Transactions* of that society has preserved many a student from the premature publication of unfinished work.

One of the principal obstacles to the rapid diffusion of a new idea lies in the difficulty of finding suitable expressions to convey its essential point to other minds. Words may have to be strained into a new sense, and scientific controversies constantly resolve themselves into differences about the meaning of words. On the other hand, a happy nomenclature has sometimes been more powerful than rigorous logic in allowing a new train of thought to be quickly and generally accepted. A good example is furnished by the history of the science of energy. The principle of the conservation of energy has undoubtedly gained a more rapid and general acceptance than it would otherwise have had by the introduction of the word potential energy. A great theorem, which in itself seems to me to be an intricate one, has been simplified by calling something energy which, in the first place, is only a deficiency of kinetic energy. The only record I can find on the history of the expression is given in Tait's "Thermodynamics," wherein the term statical energy is ascribed to Lord Kelvin, and that of potential energy to Rankine. It would be of interest to have a more detailed account on the origin of an expression which has undoubtedly had a marked influence not only on the physics, but also on the metaphysics of our time. But while fully recognising the very great advantage we have derived from this term "potential energy," we ought not, at the same time, to lose sight of the fact that it implies something more than can be said to be proved. It is easy to overstep the legitimate use of the word. Thus, when Prof. Lodge* attempts to prove that action at a distance is not consistent with the doctrine of energy, he cannot, in my opinion, justify his opinion except by assuming that all energy is ultimately kinetic. That is a plausible but by no means a necessary theory. Efforts have been made to look on energy as on something which can be labelled and identified through its various transformations. Thus we may feel a certain bit of energy radiating from a coal fire, and if our knowledge was complete we ought to be able to fix the time at which that identical bit of energy left the sun and arrived on the surface of the earth, setting up a chemical action in the leaves of the plant from which the coal has been derived. If we push this view to a logical conclusion, it seems to me that we must finally arrive at an atomic conception of energy which some may consider an absurdity. Let, for instance, a number of articles, P_1, P_2, etc., in succession, strike another particle, Q. How can we in the translatory energy of the latter identify the parts which P_1, P_2, etc., have contributed? According to Prof. Lodge's view, we should be able to do so, for if the particle, Q, in its turn gives up its energy to others—say, R_1, R_2, R_3, etc.—we ought to be able to say whether the energy of P_1 has ultimately gone into R_1 or into R_2, or is divided between them. It is only by imagining that all energy is made up of a finite number of bits, which pass from one body to another, that we can defend the idea of considering energy as being capable of being "labelled."

In the expressions we adopt to describe physical phenomena we necessarily hover between two extremes. We either have to choose a word which implies more than we can prove, or we have to use vague and general terms which hide the essential point, instead of bringing it out. The history of electrical theories furnishes a good example. The terms positive and negative electricity committed us to something definite; we could reckon about quantities of electricity, and form some definite notion of electrical currents as a motion of the two kinds of electricity in opposite directions. Now we have changed all that; we speak of electric displacements, but safeguard ourselves by saying that a displacement only means a vector quantity, and not necessarily an actual displacement. We speak of lines and tubes of force not only as a help to realise more clearly certain analytical results, but as implying a physical theory to which, at the same time, we do not wish to commit ourselves. I do not find any fault with this, for it is a perfectly legitimate and necessary process to state the known connection between physical phenomena in some form which introduces the smallest number of assumptions. But the great question, "What is electricity?" is not touched by these general considerations. The brilliant success with which Maxwell's investigations have been crowned is apt to make us overrate the progress made in the solution of that question. Maxwell and his followers have proved the important fact that optical and electrical actions are transmitted through the same medium. We may be said to have arrived in the subject of electricity at the stage in which optics was placed before Young and Fresnel hit on the idea of transverse vibrations, but there is no theory of electricity in the sense in which there is an elastic solid theory of light. If the term electrical displacement was taken in its literal sense, it would mean that the electric current consists of the motion of the ether through the conductor. This is a plausible hypothesis, and one respecting which we may obtain experimental evidence. The experiments of Rayleigh and others have shown that the velocity of light in an electrolyte through which an electric current is passing, is, within experimental limits, the same with and against the current. This result shows that if an electrical current means a motion of the ether the velocity of the medium cannot exceed 10 metres a second for a current density of one ampere per square centimetre. This, then, is the upper limit for a possible velocity of the medium. Can we find a lower limit? The answer to that question depends on the interpretation of a well-known experiment of Fizeau, who found that the speed of light is increased if it travels through water which moves in the same direction as the light. If this experiment implies that the water carries the ether with it, and if a motion of the ether means an electric current, we should be led to the conclusion that a current of water should deflect a magnet in its neighbourhood. An experiment made to that effect would almost certainly give a negative result, and would give us a lower limit for the velocity of the medium corresponding to a given current. Such an experiment, together with that of Rayleigh, would probably dispose of the theory that an electric current is due to a translatory velocity of the medium. This would be an important step, and it would be worth while to arrive at a final settlement of the question.* The whole question of the relation between the motion of matter and motion of the medium is a vital one, and we shall probably not make any serious advances until experiment has found a new opening. But we must expect many negative results before some clue is discovered. Nor can we attach much importance to negative results unless they are made by someone in whose care and judgment we place full [illegible]. We should all the more, therefore, recognise the courage and perseverance of those who spend their valuable time in such investigations as Prof. Lodge has recently undertaken. That ultimately some relation will be found between moving matter and [illegible] action there is no reasonable doubt.

One of the most hopeful openings for new investigations [illegible] always been found in the pursuing of a theory to its logical conclusions, and there is one result of the electromagnetic [illegible] light, which has not, in my opinion, received the share of [illegible] which it deserves. When sound passes through air it [illegible] gated more quickly with the wind than against it, and we [illegible] easily find the velocity relative to the earth by combining the ordinary sound velocity with the velocity of the wind. [illegible] when any waves pass through a medium moving with [illegible] velocity, the waves being due to internal stresses in the medium, we may treat of the velocity of the waves [illegible] dently of that of the medium, and say that the wave [illegible] in the direction of motion of the medium, and relative [illegible] fixed body, is the sum of the wave velocity calculated [illegible] supposition that the medium is at rest and the velocity of the medium. Prof. J. J. Thomson,† applying Maxwell's equations, [illegible] arrived at a different result for electromagnetic waves, and [illegible] come to the conclusion that in order to get the velocity of [illegible] along a stream of flowing water we have to add to the velocity of light only half the velocity of water. The following considerations suggest themselves to me with respect to this result. Maxwell's theory is founded on certain observed effects, which all depend [illegible] the relative motion of matter. A result such as the one [illegible] to implies actions depending on absolute motion, and [illegible] therefore to point to something which has been introduced [illegible] the equations for which there is no experimental evidence. The only assumption clearly put down by Maxwell is that [illegible] magnetic actions are transmitted through the medium, [illegible] is possible that that assumption necessarily carries [illegible] J. J. Thomson's result with it. If a careful examination [illegible] the subject should show that this is the case, we are [illegible] face to face with a serious difficulty. It is said with [illegible] to be one of the great advantages of Maxwell's theory [illegible] does away with action at a distance; but what do we [illegible] replace action at a distance by something infinitely more [illegible] to conceive—namely, internal stresses of a medium depending [illegible] the velocity of the medium through space? I can only [illegible] loophole through which to escape—namely, that Maxwell's [illegible] is not homogeneous, but consists of two parts, and that if we [illegible] of the medium as moving, we mean the motion of one of these parts relative to the other.

While we may hope to obtain important results from an investigation of the relation between what we call electricity and the medium, we must not lose sight of another avenue [illegible] relation between electricity and chemical effects. The passage of electricity through gases presents us with a complicated [illegible] to which a number of physicists have given their attention [illegible] years. There seems no reasonable doubt that electricity in a gas is conveyed by the diffusion of particles conveying high charges, probably identical with those carried by the electrolytic [illegible]. The fact that this convection is a process of diffusion with [illegible] tively small velocity is shown by the experimental result [illegible] path of the discharge is affected by any bodily motion of [illegible] which conveys the current. Even the convection currents [illegible] the heat produced by the discharge itself are sufficient to [illegible]

* *Phil. Mag.*, vol. xl., p. 38 (1881).

* Fizeau's result must either be due to the motion of [illegible] through the medium or to the fact that moving matter [illegible] ether with it. If it is due to the former cause, and [illegible] not carry the ether with it, may we not consider that matter [illegible] through the ether, that is a relative motion of matter and [illegible] must produce effects equal and opposite to those of ether [illegible] through matter? In that case the reasoning in the [illegible] *mutatis mutandis*, hold good.

† *Phil. Mag.*, vol. ix, p. 284 (1880).

the luminous column which marks the passage of the current. The most puzzling fact, however, connected with the discharge of electricity through gases consists in the absence of symmetry at the positive and negative poles. There must be some difference between a positively and negatively charged atom which seems of fundamental importance in the relation between matter and what we call electricity. A discussion of the various phenomena attending the discharge of electricity through gases seems to me to point to a conclusion which may possibly prove a step in the right direction. A surface of separation between bodies having different conductivities becomes electrified by the passage of a current, while at the surface between two chemically distinct bodies we have, according to Helmholtz, a sheet covered at the two sides with opposite electricities. These surface electrifications are not merely imaginary layers invented to satisfy mathematical surface conditions. They can be proved to be realities. Thus, when one electrolyte floats on another, the specific resistances being different, we often observe secondary chemical effects due to the action of the ions which carry the surface electrification. If the passage of electricity from the solid to the gas involves some work done, we must expect a double sheet of electricity at the boundary, the gas in contact with the cathode becoming positively, and that in contact with the anode negatively, electrified. *A priori* we can form no idea how a layer of gas, the atoms of which carry charges, will behave. The ordinary proof that all electrification must be confined to the surface implies that all forces act according to the law of the inverse square, but where we have also to consider molecular forces, I see no reason why the electrification at a surface may not stretch across a layer having a thickness comparable with the mean free path of the molecule. It is here that there seems to be the fundamental difference between positive and negative electricity. A negative electrification of the gas, like that of a solid or a liquid, seems always confined to the surface, and no one has ever observed a volume electrification of negative electricity. The case is different for the positively electrified part of the gas. Wherever from other considerations we should expect a positively electrified surface sheet, we always get a layer of finite thickness. The result implies a different law of impact between positively and negatively electrified ions, but I see no inherent improbability in this. That the cathode let into a gas is surrounded by a positively electrified layer of finite thickness extending outwards must be considered as an established fact, and several of the characteristic features of the discharge are explained by it. The large fall of potential at the cathode can also be explained on the view which I have put forward, for in order to keep up the discharge there must be a sufficient normal force at the surface, and if this force is not confined to the surface, but necessarily stretches across a finite layer, the fall of potential must be multiplied a great number of times. Similarly Goldstein has shown that some of the phenomena of the cathode are observed at every place at which the positive current flows from a wide to a narrow part of a column of gas. At such places we should expect a positive surface electrification, and here, again, the whole appearance tends to show that we are dealing with a positive volume electrification. No corresponding phenomena are observed when the current passes from the narrow to the wide part. The fact that in all cases experimented upon positive volume electrifications are observed, but never similar negative electrifications, is surely of significance.

Some of the results recently brought to light by investigations on the discharge of electricity have interesting cosmical applications. Thus it is found that such a discharge through any part of a vessel containing a gas converts the whole gas into a conductor.* The dissociation which we imagine to take place in a liquid before electrolytic conduction takes place must be artificially produced in a gas by the discharge itself. We may imitate in gases which have thus been rendered conductive many of the phenomena hitherto restricted to liquids; thus I hope to bring to the notice of this meeting cases of primary and secondary cells in which the electrolyte is a gas. There are other ways in which a gas can be put into that sensitive state in which we may treat it as a conductor, and we have every reason to suppose that the upper regions of our atmosphere are in this state. The principal part of the daily variation of the magnetic needle is due to causes lying outside the surface of the earth, and is in all probability only an electromagnetic effect due to that bodily motion in our atmosphere which shows itself in the diurnal changes of the barometer. A favourite idea of the late Prof. Balfour Stewart will thus probably be confirmed. The difference in the diurnal range between times of maximum and times of minimum sun-spots is accounted for by the fact that the atmosphere is a better conductor at times of maximum sun-spots. The mention of sun-spots raises a point not altogether new to this section. Careful observations of celestial phenomena may suggest to us the solution of many mysteries which are now puzzling us. Consider, for instance, how long it would have taken to prove the universal property of gravitational attraction if the record of planetary motion had not come to the philosopher's help. And surely the most casual observation of cosmical effects teaches us how much we have yet to learn.

The statement of a problem occasionally helps to clear it up, and I may be allowed, therefore, to put before you some questions, the solution of which seems not beyond the reach of our powers.

1. Is every large rotating mass a magnet? If it is, the sun must be a powerful magnet. The comets' tails, which eclipse observations show stretching out from our sun in all directions, probably consist of electric discharges. The effect of a magnet on the discharge is known, and careful investigations of the streamers of the solar corona ought to give an answer to the question which I have put.*

2. Is there sufficient matter in interplanetary space to make it a conductor of electricity? I believe the evidence to be in favour of that view. But the conductivity can only be small, for otherwise the earth would gradually set itself to revolve about its magnetic pole. Suppose the electric resistance of interplanetary space to be so great that no appreciable change in the earth's axis of rotation could have taken place within historical times, is it not possible that the currents induced in planetary space by the earth's revolution may, by their electromagnetic action, cause the secular variation of terrestrial magnetism? There seems to me to be here a definite question capable of a definite answer, and as far as I can judge without a strict mathematical investigation the answer is in the affirmative.

3. What is a sun spot? It is, I believe, generally assumed that it is analogous to one of our cyclones. The general appearance of a sun spot does not show any marked cyclonic motion, though what we see is really determined by the distribution of temperature and not by the lines of flow. But a number of cyclones clustering together like the sun-spots in a group should move round each other in a definite way, and it seems to me that the close study of the relative positions of a group of spots should give decisive evidence for or against the cyclone theory.

4. If the spot is not due to cyclonic motion, is it not possible that electric discharges setting out from the sun, and accelerating artificially evaporation at the sun's surface, might cool those parts from which the discharge starts, and thus produce a sun spot? The effects of electric discharges on matters of solar physics have already been discussed by Dr. Huggins.

5. May not the periodicity of sun-spots, and the connection between two such dissimilar phenomena as spots on the sun and magnetic disturbances on the earth, be due to a periodically recurring increase in the electric conductivity of the parts of space surrounding the sun? Such an increase of conductivity might be produced by meteoric matter circulating round the sun.

6. What causes the anomalous law of rotation of the solar photosphere? It has long been known that groups of spots at the solar equator perform their revolution in a shorter time than those in a higher latitude; but spots are disturbances which may have their own proper motions. Dunér has shown, however, from the displacement of the Fraunhofer lines, that the whole of the layer which produces these lines follows the same anomalous law, the angular velocity at a latitude of 75deg. being 30 per cent. less than near the equator.‡ As all causes acting within the sun might cause the angular velocity of the sun to be smaller at the equator than at other latitudes, but could not make it greater, the only explanation open to us is an outside effect either by an influx of meteoric matter, as suggested by Lord Kelvin, or in some other way. If we are to trust Dr. Welsing's result that faculæ which have their seat below the photosphere revolve in all latitudes with the same velocity, which is that of the spot velocity in the equatorial region, we should have to find a cause for a retardation in higher latitudes rather than for an acceleration at the equator. The exceptional behaviour of the solar surface seems to me to deserve very careful attention from solar physicists. Its explanation will probably carry with it that of many other phenomena.

In conclusion, I should like to return for an instant to the question whether it is possible by any means to render the progress of science more smooth and swift. If there is any truth in the idea that two types of mind are necessary, the one corresponding to the boiler and the other to the cooler of a steam engine, it must also be true that some place must be found where the two may bring their influence to bear on each other. I venture to think that no better ground can be chosen than that supplied by our meetings. We hear it said that the British Association has fulfilled its object: we are told that it was originally founded to create a general interest in scientific problems in the towns in which it meets, and now that popular lectures and popular literature are supposed to perform that work more satisfactorily, we are politely asked to commit the happy despatch. There is no need to go back to the original intention of those who have founded this institution, which has at any rate adapted itself sufficiently well to the altered circumstances to maintain a beneficial influence in scientific research. The free discussion which takes place in our sections, the interchange of ideas between men who during the rest of the year have occupied their minds, perhaps too much, with some special problem, the personal intercourse between those who are beginning their work with sanguine expectations, and those who have lost the first freshness of their enthusiasm, should surely one and all ensure a long prosperity to our meetings. If we cannot claim any longer to sow the seeds of scientific interest in the towns we visit, because the interest is established, we can at any rate assure those who so kindly offer us hospitality that they are helping powerfully in the promotion of the great object which we all have at heart.

* An experiment by Hittorf (*Wied. Ann.*, VII., p. 614) suggested the probability of this fact, which was proved independently by Arrhenius and myself.

* The efforts of Mr. Bigelow have a bearing on this point, also some remarks which I have made in a lecture before the Royal Institution (*Proc.* Roy. Inst., 1891), but nothing decisive can be asserted at present.

† "Oefvers af Kongl. Vetensk. Ak. Forhandl.," 47 (1890).

‡ Although the importance of M. Dunér's results would make an independent investigation desirable, the measurements of Mr. Crew, who by a much inferior method arrived at other results, cannot have much weight as compared with those of Dunér.

Address to the Mechanical Science Section.

BY W. CAWTHORNE UNWIN, F.R.S., M.I.C.E., PRESIDENT OF THE SECTION

By what process selection is made of a sectional president of the British Association is to me unknown. I may confess that it was pleasant to receive the request of the council to preside at the meetings of Section G, even though much of the pleasure was due to its unexpectedness. I ventured to believe I might accept the honour gratefully, trusting to your kindness to assist me in fulfilling its obligations. Amongst engineers there are many with greater claims than I have to such a position, and who could speak to you from a wider practical experience. Here, in Section G, I think it may be claimed that the profession of engineering owes much to some who from circumstances or natural bias have concerned themselves more with those scientific studies and experimental researches which are useful to the engineer, than with the actual carrying on of engineering operations. Here, at so short a distance from the university where Rankine and James Thomson laboured, I may venture to feel proud of being amongst those whose business it has been rather to investigate problems than to execute works.

The year just passed is not one unmemorable in the annals of engineering. By an effort remarkable for its rapidity, and as an example of organisation of labour, the broad gauge system has been extinguished. It has disappeared like some prehistoric mammoth, a large limbed organism, perfect for its purpose and created in a generous mood, but conquered in the struggle for existence by smaller but more active rivals. If we recognise that the great controversy of 50 years ago has at last been decided against Brunel, at least we ought to remember that the broad gauge system was one only of many original experiments, due to his genius and courage, experiments in every field of engineering, in bridge building, in locomotive design, in ship construction, the successes and failures of which have alike enlarged the knowledge of engineers and helped the progress of engineering. The past year has seen the completion of the magnificent scheme of water supply for Liverpool from the Vyrnwy, carried out from 1879 to 1885 by Mr. Hawksley and Mr. Deacon, and since then completed under the direction of the latter engineer. This is one of the largest and most striking of those works of municipal engineering rendered necessary by the growth of great city communities and made possible by their wealth and public spirit. For the supply of water to Liverpool, the largest artificial lake in Europe has been created in mid Wales by the construction across a mountain valley of a dam of cyclopean masonry, itself one of the most remarkable masonry works in the world. The lake contains an available supply of over 12,000 million gallons, its size having been determined not only to supply 40 million gallons daily for the increasing demand of Liverpool, but also to meet the necessity imposed by Parliament that an unprecedentedly large compensation, amounting to 10 million gallons daily and 50 million gallons additional on 32 days yearly, should be afforded to the Severn. The masonry dam, though a little less in height than some of the French dams, is of greater length. It is nearly double the length of the great dam at Verviers.* Although masonry dams were an old expedient of engineers, it is in quite recent times, and chiefly in consequence of the scientific investigations of French engineers, that they have been revived in engineering practice. Since the construction of the Vyrnwy dam, another very large dam, the Tansa dam, has been completed in Bombay. This dam has a length of two miles and a height of 118ft., and it is 100ft. thick at the base. The reservoir will supply 100 million gallons per day. In the United States a still greater work of the same kind has been commenced on the Croton river, in connection with the water supply of New York. This dam will have a length of 2,000ft., and a height of 285ft. Its greatest thickness will be 215ft. It will be very much the boldest work of its kind. Returning to the Liverpool supply, the water taken from the lake at the most suitable level into a straining tower provided with very complete hydraulic machinery, passes through the Hirnant tunnel, and thence by an aqueduct, partly consisting of rock tunnels, partly of pipes 39in. to 42in. in diameter, 68 miles in length, being the longest aqueduct yet constructed. The crossing of the Mersey by an aqueduct tunnel has proved the greatest engineering difficulty to be surmounted. The tunnel has been carried through layers of running sand, gravel and silt. At first slow progress was made, but later, by the adoption of the Greathead system of shield with air locks and air compressing machinery, as much as 57ft. of tunnel were driven and lined in one week. The whole work is now complete, and Liverpool has available an extra supply of very pure water, amounting to 40 million gallons daily. A scheme of water supply for Manchester from Lake Thirlmere in Westmoreland, on an equally large scale, is approaching completion. Birmingham is likely to carry out another work of the same kind, and London, at a greater distance from pure water sources, and under greater difficulties from the complexity of existing interests, has come to realise that, within 50 years, a population of 12½ millions will probably have to be provided for. To supply such a population, a volume of water is required ten times as great as the whole available supply from Lake Vyrnwy.

Here in Edinburgh one remembers that the birthplace of the steam engine is near at hand. A century and a quarter ago, James Watt made an invention which has profoundly influenced all the conditions of social, national, commercial, and industrial life. It is due to the steam engine more than to any other single cause that the population in this country has tripled since the beginning of the century, and that we have become dependent on steam power for fuel, for transport, for manufactures, in many cases for water supply, for sanitation, and for artificial light. From some German statistics it appears that there are probably now in the world, employed in industry, steam engines exerting 49 million horse power, besides locomotives exerting six million horse power. Engines in steamships are not included. The steam engine has become a potent factor in civilisation, because it places at our disposal mechanical energy at a sufficiently low cost, and the efforts of engineers have been steadily directed to diminishing the cost at which steam power is produced. Members of one great branch of our profession are much concerned in the production of mechanical energy at a sufficiently cheap rate. They require it in very large quantity for transformation into light and for retransformation into mechanical energy under conditions more convenient than the direct use of steam power. Perhaps it will not be inappropriate if in Section G, I first discuss briefly some of the causes which have made the steam engine inefficient and the extent to which we are getting to a scientific knowledge of the methods of evading them. I propose then to consider some of the methods of economising the cost and increasing the convenience of mechanical power by generating it at central stations and distributing it, and, lastly, how far means of transporting energy are likely to make available cheaper sources of energy than steam power. Let us go back for a moment to James Watt. The most distinct feature about the invention of the steam engine is that it arose out of studies of such questions as the relation of pressure and temperature of steam, the heat absorbed in producing it, and its volume at different pressures. Armed with this knowledge Watt was able to determine that the quantity of steam used in a model atmospheric engine was enormously greater than that due to the volume described by the piston. There was waste of steam. To discover the loss was to get on the path of finding a remedy. The separate condenser, by diminishing cylinder condensation, annulled a great part of the loss. So great was Watt's insight into the action of the engine that he was able to leave it so perfect that, except in one respect, little remained for succeeding engine builders, except to perfect the machines for its manufacture, to improve its details and to adapt it to new purposes. Now it very early became clear that there were two directions of advance which ought to secure greater economy. Simple mechanical indications showed that increased expansion ought to ensure increased economy. Thermo-dynamic considerations indicated that higher pressures, involving a greater temperature range of working, ought to secure greater economy. But in attempting to advance in either of these directions, engineers were more or less disappointed. Some of Watt's engines worked with 8lb. of coal per indicated horse power per hour. Many engines with greater pressures and longer expansions have done but little better. The history of steam engine improvement for a quarter of a century has been an attempt to secure the advantages of high pressures and high ratios of expansion. The difficulty to be overcome has proved to be due to the same cause as the inefficiency of Watt's model engine. The separate condenser diminished, but did not annul the action of the cylinder wall. The first experiments which really startled thoughtful steam engineers were those made by Mr. Isherwood between 1860 and 1865. Mr. Isherwood showed that in engines such as those then in use in the United States Navy, with the large cylinders and low speeds then prevalent, any expansion of the steam beyond three times led, not to an increased economy, but to an increased consumption of steam. Very little later than this M. Hirn undertook, in 1873-5, his classical researches on the action of the steam in an engine of about 150 i.h.p. Experiments of greater accuracy or completeness, or of greater insight into the conditions which were important, have never since been made, and Hirn with his assistants, MM. Hallauer and Dwelshauvers Dery, has determined, once for all, the whole method of a perfect steam engine trial. M. Hirn was the first to clearly realise that the indicator gives the means of determining the steam present in the cylinder during every period of the cycle of the engine. Consequently, superheating in ordinary cases being out of the question, we have the means of determining the heat present and the heat already converted into work. The heat delivered into the engine is known from boiler measurements, combined with calorimetric tests of the quality of the steam, tests which Hirn was the first to undertake. The balance of heat unaccounted for is, then, a waste or loss due to causes which have to be investigated. Hirn originated a complete method of analysing an engine test, showing at every stage of the operation the heat accounted for and a balance of heat unaccounted for, and the latter proved to be a very considerable quantity. Meanwhile theoretical writers, especially Rankine and Clausius, had been perfecting a thermo-dynamic theory of the steam engine based primarily on the remarkable and irrefragable principles of Carnot. The result of Hirn's analysis was to show that these theories applied to the actual steam engine, were liable to lead to errors of 50 or 60 per cent., the single false assumption being made that the interaction between the walls of the cylinder and the steam was an action small enough to be negligible.

In this country Mr. Mair Rumley, following Hirn's method, made a series of experiments on actual engines with great care and accuracy and completeness. All these experiments demonstrated the fact of a large initial condensation of steam on the walls of the cylinder, alike in jacketed and unjacketed engines. The condensed steam is re-evaporated partially during expansion, be-

* The length of the dam from rock to rock is 1,172ft. Height from lowest part of foundation to parapet of carriageway, 161ft. Height from bed of river to overflow sill, 84ft. Thickness of masonry at base, 120ft.

mainly during exhaust, and serves as a mere carrier of heat from boiler to condenser, in conditions not permitting its utilisation in producing work. It became clear from Hirn's experiments, if not from the earlier experiments of Isherwood, that for each engine there is a particular ratio of expansion for which the steam expenditure per horse-power is least. Prof. Dery has since deduced from them that the practical condition of securing the greatest efficiency is that the steam at release should be nearly dry. In producing that dryness the jacket has an important influence. In spite of much controversy amongst practical engineers about the use of the jacket, it does not appear that any trustworthy experiment has yet been adduced in which there was an actual loss of efficiency due to the jacket. In the older type of comparatively slow engines it is a rule that the greater the jacket condensation the greater the economy of steam, even when the jacket condensation approaches 20 per cent. of all the steam used. It appears, however, that as the speed of the engine increases, the influence of the jacket diminishes, so that for any engine there is a limit of speed at which the value of the jacket becomes insignificant.

Among steam engine experiments directed specifically to determine the action of the cylinder walls, those of the late Mr. Willans should be specially mentioned. Mr. Willans's death is to be deplored as a serious loss to the engineering profession. His steam engine experiments, some of them not yet published, are models of what careful experiments should be. They are graduated experiments designed to indicate the effect of changes in each of the practically variable conditions of working. They showed a much greater variation of steam consumption (from 40lb. to 18lb. per indicated horse-power hour) in different conditions of working than, I think, most practical engineers suspected, and this has been made more significant in later experiments on engines working with less than full load. The first series showed that in full load trials the compound was superior to the single engine in practically all the conditions tried, but that the triple was superior to the compound only when certain limits of pressure and speed were passed.

As early as 1878 Prof. Cotterill had shown that the action of a cylinder wall was essentially equivalent to that of a very thin metallic plate, following the temperature of the steam. The exceedingly rapid dissipation of heat from the surface during exhaust especially being due to the evaporation of a film of water initially condensed on its surface. In permanent *regime* the heat received in admission must be equal to that lost after cut off. In certain conditions it appeared that a tendency would arise to accumulate water on the cylinder surfaces, with the effect of increasing in certain cases the energy of heat dissipation. Recently Prof. Cotterill has been able to carry much further the analysis of the complex action of condensation and re-evaporation in the cylinder and to discriminate in some degree between the action of the metal and the more ambiguous action of the water film. By discarding the less important actions, Prof. Cotterill has found it possible to state a semi-empirical formula for cylinder condensation in certain restricted cases which very closely agree with experiments on a wide variety of engines. It is to be hoped that, with the data now accumulating, a considerable practical advance may be made in the clearing up of this complex subject. There are, no doubt, some people who are in the habit of depreciating quantitative investigations of this kind. They are as wise as if they recommended a manufacturer to carry on his business without attending to his account books. Further, the attempt to obtain any clear guidance from experiments on steam engines has proved a hopeless failure without help from the most careful scientific analysis. There is not a fundamental practical question about the thermal action of the steam engine, neither the action of jackets or of expansion or of multiple cylinders, as to which contradictory results have not been arrived at, by persons attempting to deduce results from the mass of engine tests without any clear scientific knowledge of the conditions which have affected particular results. In complex questions fundamental principles are essential in disentangling the results. Interpreted by what is already known of thermo-dynamic actions, there are very few trustworthy engine tests which do not fall into a perfectly intelligible order. There is only one known method, not now much used, by which the cylinder condensation can be directly combated. Thirty years ago superheating the steam was adopted with very considerable increase of economy. It is likely that it was thought by the inventor of superheating that an advantage would be gained by increasing the temperature range. If so, his theory was probably a mistaken one. For the cooling action of the cylinder is so great that the steam is reduced to saturation temperature before it has time to do work, but the economy due to superheating was unquestionable, and was very remarkable considering how small a quantity of heat is involved in superheating. The heat appears to diminish the cylinder wall action so much as almost to render a jacket unnecessary. The plan of superheating was abandoned from purely practical objections, the superheaters then constructed being dangerous. Recently superheating has been tried again at Mulhouse by M. Meunier, and his experiments are interesting because they are at higher pressures than in the older trials and with a compound engine. It appears that even when the superheater was heated by a separate fire there was an economy of steam of 25 to 30 per cent. and an economy of fuel of 20 to 25 per cent., and four boilers with superheating were as efficient as five without it. may be pointed out as a point of some practical importance that a trustworthy method of superheating could be found, the vantage of the triple over the compound engine would be much minished. For marine purposes the triple engine is perfectly apted. But for other purposes it is more costly than the compound engine, and it is less easily arranged to work efficiently with a varying load. There does not seem much prospect of exceeding the efficiency attained already in the best engines, though but few engines are really so efficient as they might be, and there are still plenty of engines so designed that they are exceedingly uneconomical. The very best engines use only from 12lb. to 13lb. of steam per indicated horse-power hour, having an absolute efficiency reckoned on the indicated power of 16 per cent., or reckoned on the effective power, 13 per cent. The efficiency, including the loss in the boiler, is only about 9 per cent. But there are internal furnace engines of the gas-engine or oil-engine type in which the thermal efficiency is double this.

In his interesting address to this section in 1878, Mr. Easton expressed the opinion that the question of water power was one deserving more consideration than it had lately received, and he pointed to the variation of volume of flow of streams as the principal objection to their larger utilisation. Since that time the progress made in systems of transporting and distributing power has given quite a new importance to the question of the utilisation of water power. There seems to be a probability that in many localities water power will, before long, be used on a quite unprecedented scale, and under conditions involving so great convenience and economy that it may involve a quite sensible movement of manufacturers towards districts where water power is available. If we go back to a period not very distant in the history of the world, to the middle of the last century, we reach the time when textile manufactures began to pass from the condition of purely domestic industries to that of a factory system. The fly shuttle was introduced in 1750, the spinning jenny was invented in 1767, and Crompton's machine only began to be generally used in 1787. It was soon found that the new machines were most suitably driven by a rotary motion, and after some attempts to drive them by horses, water power was generally resorted to. In an interesting pamphlet on the "Rise of the Cotton Trade," by John Kennedy of Ardwick Hall, written in 1815, it is pointed out that the necessity of locating the mills where water power was available had the disadvantages of taking them away from the places where skilled workmen were found, and from the markets for the manufactured goods. Nevertheless, Mr. Kennedy states that for some time after Arkwright's first mill was built at Cromford, all the principal mills were erected near river falls, no other power than water power having been found practically useful. "About 1790," says Mr. Kennedy, "Mr. Watt's steam engine began to be understood, and waterfalls became of less value. Instead of carrying the workpeople to the power, it was found preferable to place the power amongst the people." The whole tendency of the conditions created by the use of steam power has been to concentrate the industrial population in large communities, and to restrict manufacturing operations to large factories. Economy in the production of power, economy in superintendence, the convenience of the subdivision of labour, and the costliness of the machines employed, all favoured the growth of large factories. The whole social conditions of manufacturing centres have been profoundly influenced by these two conditions—that coal for raising steam can be easily brought to any place where it is wanted, and that steam power is more cheaply produced on a large scale than on a small scale. It looks rather, just now, as if facilities for distributing power will to some extent reverse this tendency. Let me first point out that water power, where it is available, is so much cheaper and more convenient than steam power that it has never been quite vanquished by steam power.

I find, from a report by Mr. Weissenbach, that, in 1876, 70,000 h.p. derived from waterfalls were used in manufacturing in Switzerland. According to a census in 1880, it appears that the total steam and water power employed in manufacturing operations in the United States was 3,400,000 h.p. Of this, 2,185,000 h.p., or 64 per cent., was derived from steam, and 1,225,000 h.p., or 36 per cent., from water. In the manufacture of cotton and woollen goods, of paper and of flour, 760,000 h.p. were obtained from water, and 515,000 h.p. from steam. If statistics could be obtained from other countries, I believe it would be found that a very large amount of water power is actually made available. The firm of Escher Wyss and Company, of Zurich, have constructed more than 1,800 turbines of an aggregate power of 111,460 h.p. With a very limited exception all the water power at present used is employed in the neighbourhood of the fall where it is generated. If means were available for transporting the power from the site of the fall to localities more convenient for manufactures, there can be no doubt that a much larger amount of water power would be used, and the relative importance of water and steam power in some countries would probably be reversed. It is because recent developments seem to make such a transport of power possible without excessive cost, and without excessive loss, that a most remarkable interest has been excited in the question of the utilisation of water power. Take the case of Switzerland, for instance. At the present time Switzerland is said to pay to other countries £800,000 annually for coal. But the total available water power of Switzerland is estimated at no less than 582,000 h.p., of which probably only 80,000 are at present utilised. I found a year ago that nearly every large industrial concern in Switzerland was preparing to make use of water power, transported a greater or less distance. Besides the great schemes actually carried out at Schaffhausen, Bellegarde, Geneva, and Zurich, where water power is already utilised on a very large scale, there is a project to develop 10,000 h.p. on the Dranse, near Martigny. Hence, it is easy to see that problems of distribution of power—that is, the transformation of energy into forms easily transportable and easily utilisable—have now a great interest for engineers. Besides the power required for manu-

facturing operations, there is a steadily increasing demand for easily available mechanical energy in large towns. For tramways, for lifts, for handling goods, for small industries, for electric lighting, and sometimes for sanitation, power is required. Hitherto steam engines, or more lately gas engines, have been used, placed near the work to be done. But this sporadic generation of power is uneconomical and costly, especially when the work is intermittent; the cost of superintendence is large, and the risk of accident considerable. Hence attention is being directed to systems in which the mechanical energy of fuel or falling water is first generated in large central stations, transformed into some form in which it is conveniently transportable and capable of being rendered available by simpler motors than steam engines.

Just as in great towns it has become necessary to supersede private means of water supply by a municipal supply; just as it has proved convenient to distribute coal gas for lighting and heating, and to provide a common system of sewerage, so it will probably be found convenient to have in all large towns some means of obtaining mechanical power in any desired quantity at a price proportionate to the quantity used, and in a form in which it can be rendered available, either directly or by simple motors requiring but little skilled superintendence.

Teledynamic Transmission.—First, then let me say a few words as to modes of distributing power which it is possible to adopt. In 1850, at Logelbach in Alsace, M. Ferdinand Hirn used a flat steel belt to transmit power directly a distance of 80 metres. Subsequently a wire rope was used on grooved pulleys. This worked so well that a second transmission to a distance of 240 metres was erected. The details of the system were worked out with great care with a view to securing the least cost of construction, the least waste of energy, and the greatest durability of the ropes. So successful did this system of teledynamic transmission prove that within 10 years M. Martin Stein, of Mulhouse, had erected 400 transmissions, conveying 4,200 h.p., and covering a distance of 72,000 metres. Just at this time a very able and far-seeing manufacturer at Schaffhausen, Herr Moser, had formed a project for reviving the failing industries of the town by utilising part of the water power of the Rhine. Hirn's system of wire-rope transmission rendered this project practicable. The works were commenced in 1863. Three turbines of 750 h.p. were erected on a fall which varies from 12ft. to 16ft., created by a weir across the river. From the turbines the power is transmitted by two cables, in one span of 392ft., across the river. Similar cables distribute the power to factories along the river bank. In 1870 the transmission extended to a distance of 3,400ft. Power is sold at rates varying from £5 to £6 per horse-power per annum. In 1887 there were 23 consumers of power paying a rental of £3,500 per annum for power. The project has been financially successful, and is still working. At Zurich, Freiberg, and Bellegarde there are similar installations, and a large scheme of the same kind has recently been carried out at Gokak in India. Wire-rope transmissions are of great mechanical simplicity, and the loss of power in transmission is exceedingly small. They are extremely suitable for certain cases where a moderate amount of power has to be transmitted a moderate distance, to one or to a few factories. On the other hand, they become cumbrous if the amount of power transmitted exceeds 600 h.p. or 1,000 h.p. The wear of the ropes, which only last a year, has proved greater than was expected, and is a source of considerable expense.

The practical introduction of a system of distributing power by pressure water is due to Lord Armstrong. Such a system involves a central pumping station, a series of distributing mains, and suitable working motors. From its first introduction the peculiar advantages of this system for driving intermittently working machines, such as lifts, dock machinery, railway cranes, and hauling gear, became obvious. But, with intermittent working machines, there arose the need of an appliance for storing energy during periods of minimum demand and restoring it in periods of maximum demand. The invention of the accumulator by Lord Armstrong made the system of hydraulic transmission a success, and at the same time fixed its character as a system specially adapted for those cases where intermittent work is required to be done. Lord Armstrong's system of hydraulic distribution by water at a pressure of 700lb. or 800lb. per square inch, with the use of accumulators for equalising the variations of supply and demand, has now been widely adopted. The most extensive scheme of that kind hitherto executed is the important scheme carried out by the Hydraulic Power Company. Over 50 miles of pressure mains have now been laid in the streets of London. The Falcon Wharf pumping station contains four sets of compound pumping engines, each of 200 h.p. Two additional pumping stations have now been erected, and 1,500 lifts are worked from the pressure mains. The minimum charge for water is 2s. per 1,000 gallons. This rate of charge is economical for such machines as lifts, but it would be extravagant for machines working continuously. It would be equivalent to a charge of nearly £50 per horse-power per year of 3,000 working hours, apart from interest and maintenance of machines.

I shall indicate later on that in some cases where local conditions are favourable, where there is cheap water power and the possibility of constructing high-level storage reservoirs, then hydraulic transmission can be adopted with success for distributing power for ordinary manufacturing purposes. But neither teledynamic transmission nor hydraulic transmission have proved suitable as methods for the general distribution of motive power from central stations. Distribution by steam and distribution by heated water have both been tried in the United States, but not with very remarkable success. Only two other methods are available, distribution by compressed air and distribution by electricity. For many years compressed air has been used to distribute power in tunnelling and mining operations to considerable distances. It is only recently that it has been used as a general method of distributing power to many consumers. In many installations the machinery has been rough and unscientific, and the waste of energy very considerable. It is through experience gained and improvements carried out in the remarkable system now at work in Paris, and known as the Popp system, that the great advantages of compressed air distribution have been proved. The Paris system has very gradually developed. About 1870 a small compressing station was erected to actuate public and private clocks by intermittent pulses of air conveyed along pipes chiefly laid in the sewers. In 1889 about 8,000 clocks were thus driven. Meanwhile the compressed air had also been applied to drive motors for small industries. The demand for power thus supplied grew so rapidly that a second compressing station was built in the Rue de Saint Fargeau. In 1889 steam air compressors of 2,000 h.p. were at work, and additional compressors were under construction. The pressure at that time was five atmospheres, and the largest air mains were 12in. in diameter. Ingenious and simple rotary machines were used as air motors for small powers, and for larger powers any ordinary steam engine was converted into an air motor. Prof. Kennedy made tests in 1889, which were communicated to this association. He found that a motor four miles from the compressing station indicated 10 h.p. for 20 i.h.p. expended at the compressing station, an efficiency of 50 per cent. only. There were then 225 motors worked from the air mains. Since 1889 more extended investigations have been made by Prof. Riedler, of Berlin, and the chief part of the waste of work has been traced to inefficiency of the air compressors. Compound air compressors of much higher efficiency have now been constructed. The plant at the St. Fargeau station has been increased to 4,000 h.p. A new station has been erected on the Quai de la Gare, intended ultimately to contain compressors of 24,000 h.p. Compressors of 10,000 h.p. are already under construction. Compressed air transmission, whether or not it is the most economical system, is undoubtedly applicable for the distribution of power on a very large scale and to very considerable distances. There is nothing in any of the appliances which is novel or imperfectly understood. The air is used in the consumer's premises in machinery of well-understood types, and old steam engines can be converted into air motors without difficulty and without alteration of existing transmissive machinery in the factories. Not least important, the air can be measured with accuracy enough for practical purposes by simple meters, and charged for in proportion to the power consumed. Air compressors and air motors are not as efficient as dynamos and electric motors, but in one respect distribution by air and electricity are similar. For distances which are not more than a few miles the loss of energy in transmission is small enough to be insignificant.

There is yet one other mode of power distribution which promises to become the most important of all, and which, in the case of transmission to very great distances, if such transmission becomes necessary, has undoubtedly great advantages over every other method.

About electrical distribution of power I shall not venture to say much, partly because I am not an electrical expert, partly because it has been lately pretty fully discussed. In the United States there has been an enormous development of electric tramways, which are essentially cases of electric power distribution. In this country we have the South London and some other railways worked electrically. There are others also on the Continent. But electrical power distribution to private consumers for industrial purposes has not yet made as much progress as might have been expected. Perhaps electrical engineers have been so busy with problems of electric lighting that they have had no time to settle the corresponding problems of power distribution. No doubt continuous-current distribution presents at the moment the fewest difficulties, or, at any rate, involves the fewest comparatively untried expedients. Some continuous-current plants for distributing power are in operation, of which, perhaps, the most interesting is that at Oyonnax, which was described in Section G last year by Prof. G. Forbes. There 300 h.p., obtained by turbines, is transmitted eight kilometres at 1,800 volts. It is then let down by motor transformers to a voltage suitable for lighting and driving motors. A number of small workshops are driven, the power being supplied at a low rent. At the Calumet and Hecla mines on Lake Superior, at the Dalmatia mines in California, and some other places, energy derived from turbines is transmitted distances of a mile or two by continuous electric currents and used in driving mining machinery, and some cases of the use of electrical distribution in this country were mentioned by my predecessor in his address last year. At Bradford a few electric motors are being worked from the electric lighting mains. The largest of these is of 20 h.p. The price at which the electricity is supplied is not given, but I believe the cost is high when reckoned for continuous working. It would seem that it must be so when the electric current is generated by steam power. At Schaffhausen an electric transmission has now been constructed alongside of the wire-rope transmission. The power is derived from two turbines, and is transmitted across the Rhine, a distance of 750 yards, at 624 volts. The current drives a spinning mill, in which the largest motor is 380 h.p. The power is sold, I believe, at £3 per horse-power of the motors per annum.

Many engineers have now apparently come to the conclusion that alternating currents will be better for power transmission to considerable distances than continuous currents. The interesting alternate-current transmission, partly for power, partly

for lighting purposes, has been for some time in operation at Genoa. On the line of the aqueduct bringing water from the Gorzente rivulet three electric stations are being established. The reservoirs are 2,050ft. above Genoa, and as this is a much greater fall than is required for water supply purposes, part can be used to generate about 1,600 h.p. In the first of the power stations erected there are turbines of 450 h.p. driving two dynamos. A second larger station was completed in November. In this there are eight alternate current dynamos of 70 h.p. each. Six alternators are worked in series, transmitting a current of 6,000 volts. The current is transmitted 16 miles by bare copper wires, 8.5 mm. diameter, placed overhead. The current is used both for lighting and power purposes. Another method of using alternating currents was adopted in the remarkable experiment at Frankfort last year. In that case energy obtained by turbines at Lauffen was transmitted to Frankfort, a distance of 108 miles, and used for lighting and driving a motor. The current was obtained at low tension, transformed up to a tension of 18,000 to 27,000 volts for transmission, and then transformed down again for distribution. The loss in the conducting wires ranged from 5 h.p. when the turbines worked at 100 h.p., to 25 h.p. when the turbines worked at 200 h.p. The efficiency of dynamo, two transformers, and line, ranged from 68 to 75 per cent., a remarkably satisfactory result. There can be little doubt that if efficient and durable transformers can be constructed, they do give a considerable advantage to an alternate-current system. To an ordinary engineer it appears also that the system of producing current at low tension in the dynamo, and using it at low tension in the motors, permits the construction of dynamos and motors more mechanically unexceptionable than those working at high voltage.

I have spoken of the growth of a demand for power distributed in a convenient form in towns. The power distribution in London, Manchester, Birmingham, and Liverpool by pressure water, and that by compressed air in Paris, shows how rapidly, when power is available, a demand for it arises. A striking instance may be found in the small town of Geneva. In 1871, soon after the completion of the earlier system of low pressure water supply, Colonel Turrettini applied to the Municipal Council to place a pressure engine on the town mains for driving the factory of the Society for Manufacturing Physical Instruments. The plan proved so convenient that nine years after, in 1880, there were in Geneva 111 water motors supplied from the low pressure mains, using 34,000,000 cubic feet of water annually, and paying to the municipality nearly £2,000 a year. The cost of the power was not low. It was charged at a rate equivalent to from £36 to £48 per horse-power per year of 3,000 working hours. But even the high price did not prevent the use of power so conveniently obtainable. Since then a high pressure water service has been established, the water being pumped by turbines in the Rhone. From this high-pressure service power is supplied more cheaply. On the high pressure system the cost of the power is about 0.7d. per horse-power hour, or £8 per horse-power for 3,000 working hours. In 1889 the annual income from water sold for power purposes on the low pressure system was £2,083, and on the high pressure system £4,500. On the high pressure system the receipts in 1889 were increasing at the rate of £880 per year. In 1889 the motive power distributed on the high pressure system alone amounted to 1,500,000 horse-power hours, there being 79 motors of an aggregate working power of 1,279 horses. In Zurich there is a quite similar system and power, amounting to 9,000,000 horse-power hours in the year, distributed hydraulically to various consumers who pay a rental of £1,200 per annum. It will be noted that all this power in Geneva and Zurich is obtained from water which has been pumped, and it is the low cost of the water power which does the pumping which makes this possible. But further, in both Geneva and Zurich the whole of the dynamos supplying electric light are also driven by turbines using pumped water. The convenience of this arises in this way. The fall obtainable in the river in both cases is a small one and varies. Large turbines are required, and these cannot work at a constant speed. Further, it is expensive to use these large low pressure turbines to drive directly dynamos which only work with a considerable load for a short portion of the day. The low pressure turbines in the river are therefore used to pump water to a high level reservoir, and they work with a constant load all the 24 hours. From the high level reservoir water is taken as power is required to drive the dynamos, and the turbines driving the dynamos are small high pressure turbines, working always on a constant fall at a regular speed and easily adjusted by a governor to a varying load. The system seems a roundabout one, but it is perfectly rational, effective, and economical.

Few persons can have seen Niagara Falls without reflecting on the enormous energy which is there continuously expended, and for any useful purpose wasted. The exceptional constancy of the volume of flow, the invariability of the levels, the depth of the plunge over the escarpment, the solid character of the rocks, all mark out Niagara as an ideally perfect water power station, while, on the other hand, the remarkable facilities of transport, both by ...eam navigation on the lakes and by four systems of railway, ...ford commercial advantages of the highest importance. From a ...chment basin of 240,000 square miles, an area greater than ...t of France, a volume of water amounting to 265,000 cubic feet ... second descends from Lake Erie to Lake Ontario, a vertical ...ance of 326ft., in 37½ miles. Supposing the whole stream could ...utilised, it would supply 7,000,000 h.p. This is more than ...uble the total steam and water power at present employed in ...nufacturing industry in the United States. Immediately ...ar the Falls the river bends at right angles, and flows ...ugh a narrow gorge. The town of Niagara Falls on the American side occupies the table-land in this angle. The earliest traders who settled near the Falls erected stream mills in the Upper River in 1725 for preparing timber. Later, the Porter family erected factories on the islands in the rapids above the Falls. It was not, however, till about 30 years ago that any systematic attempt was made to utilise part of the water power of the Falls. Then a canal was constructed from Port Day, about three-quarters of a mile above the Falls, to a forebay or head race along the cliff overlooking the lower river. In 1874 the Cataract Mill was established, taking power from this canal, and other mills were gradually erected till about 6,000 h.p. was utilised. These mills have been exceedingly prosperous, but since the growth of a feeling against the disfigurement of the Falls it has become impossible to extend works of the same kind. The idea of a method of utilising the Falls, capable of greater development, and free from the objections to the hydraulic canal with mills discharging tail water on the face of the cliff, is due to the late Mr. Thomas Evershed, division engineer of the New York State canals. He proposed to construct head race canals on unoccupied land some two miles above the Falls. From these the water was to fall through vertical turbine pits into tail race tunnels, converging into a great main tunnel, discharging into the lower river. Apart from an inappreciable diminution of the volume of flow over the Falls, this plan avoids any disfigurement of the scenery near the Falls, and permits a head of nearly 200ft. to be made available. It is, however, essential to such a plan that work should be undertaken on a very large scale. In 1886 the Niagara Falls Company was incorporated, and obtained options over a considerable area of land, extending from Port Day for two miles along the Niagara River. In 1889 the Cataract Construction Company was formed to mature and carry out the constructional works required. The present plans contemplate the utilisation of 100,000 effective horse-power. The principal work of construction is a great tunnel 7,250ft. long, which is to form a tail race to the turbines, starting from land belonging to the company, and discharging into the lower river. The tunnel is 19ft. by 21ft., or 386 square feet in area, inside a brickwork lining 16in. thick. The base of the tunnel is 205ft. below the sill of the head gate, and permits a fall of 140 to be rendered available at the turbines. The brickwork of the tunnel is lined for 200ft. from the mouth with cast-iron plates. The tunnel has been excavated with remarkable rapidity with the aid of drills worked by compressed air. The main head race, about 200ft. wide, will run for about 5,000ft., parallel with the river, having entrances from the river at both ends. Near the lower reach the Soo Paper Company is already arranging to utilise 6,000 h.p., discharging the water from the turbines through a lateral tunnel into the main tunnel. Near this lower reach will also be placed two principal power stations, from which power will be distributed, either electrically or otherwise in ways not yet fully determined. The first turbines to be erected in these power stations will be twin turbines of the outward flow type of 5,000 effective horse-power. These turbines have a vertical shaft for driving dynamos or other machinery placed above ground. According to Mr. Evershed's original plans it was intended to distribute water by surface canals to different power users, each of whom would sink his own turbine pits, connected below by lateral tunnels to the main discharge tunnel. Some of the power at Niagara will undoubtedly be used in this way, and in the case of industries requiring a large amount of power it will be economical to purchase a site and water rights. Such a plan is, however, not adapted to smaller factories. Obviously for them it would be more economical to develop the power in one or more central stations by turbines of large size under common management. Further, once given the means of distributing power instead of water, an important extension of the project becomes possible. Besides supplying power to industries which may locate themselves at Niagara, the power may be transmitted to the existing factories in Buffalo and Tonawanda. Arrangements are already proceeding to transmit 3,000 h.p. to Buffalo, a distance of 18 miles, to work an electric lighting station.

In 1890, Mr. Adams, the president of the Niagara Construction Company, visited Europe to examine systems of power distribution. It was in consequence of this visit that the important modification of the plans of the company involved in the substitution, to a large extent, of a system of power distribution for a system of water distribution came to be adopted. The American engineers were anxious to obtain the best European advice as to the methods best suited to the local conditions. A commission was formed, consisting of Lord Kelvin, Dr. Coleman Sellers, Prof. Mascart, and Colonel Turrettini, and an invitation was given to engineers and engineering firms in Europe and America to send in competitive projects for the utilisation of the power at Niagara and its distribution to different consumers at Niagara and in Buffalo by electrical or other means. Many of the plans sent in were worked out with great care and completeness. As to the hydraulic part of the projects there was some approach to general consent as to the arrangements to be adopted, but as to the methods of distributing the power there was an extraordinary diversity. Generally the commission reported in favour of electrical distribution, with perhaps a partial use of compressed air as an auxiliary method. Generally also they reported in favour of methods of distribution by continuous currents in preference to alternating currents. Since the date at which the commission reported, the Frankfort-Lauffen experiment has been made, and in the opinion of some electrical engineers a distinct advance has been achieved in the use of alternating currents at high potential. The company has not yet decided to adopt any plan for the central stations except in a tentative way. One or more turbines of 5,000 h.p. are to be erected, and probably at first this power will be distributed to Buffalo by an alternating current system. The cost of a steam horse-power at

Buffalo is reckoned at 35dol. per annum. I believe the company will be able to deliver power at from 10dol for large amounts and a greater price for small amounts, this price being reckoned for 24 hour days. The new industry of electric lighting has made necessary the provision of large amounts of motive power. Electric traction similarly depends on the supply of motive power. New chemical and metallurgical processes are being introduced which entirely depend for their commercial success on the supply of motive power at a low price. Niagara is likely to become not only a seat of large manufacturing operations of familiar types, but also the home of important new industries.

TAUNTON.

The following is the report of the Electric Lighting Committee on the purchase of the Taunton electric light works:

Your committee report that they have instructed the town clerk and borough surveyor to obtain the necessary information required to be given in, and in connection with, the memorial advertisement and draft license, which has been done. They present herewith the memorial, which will require the seal of the Council, and the drafts advertisement and license. It is necessary that a cheque for £50 should be paid to the assistant secretary of the Board of Trade, and they present cheque for signature. The town clerk has made arrangements with Messrs. Sharpe, Parker, Pritchard, and Barham, of 9, Bridge-street, Westminster, to act as his agents, and upon agency terms in obtaining the license, and he has informed the committee that he hopes he will be able to obtain the same at a less sum than was originally contemplated. Your committee have adopted the recommendation of the Lighting Committee as to the distribution of the seven additional lamps for street lighting. Your committee present herewith the report of the borough surveyor as to the alleged vibration from the electric lighting works, and as to the measures which have been taken to remedy the smoke nuisance, as to which complaints have been made. Your committee recommend that the amount necessary for the purchase of the electric lighting works, plant, machinery, and undertaking for the obtaining of the license and the costs attendant thereon, and for the improvement and extension of the works, machinery, and wires, be raised by borrowing the same under the powers and provisions of the Taunton Corporation Act, 1889, and that the same be repaid during a period of 30 years, or such other period as the Local Government Board will grant for such purpose. The following is the borough surveyor's estimate for improving and extending the works, plant, and distributing mains:

Purchase of works	£9,300
Substitution of underground for overhead wires by the Fowler Waring system	1,290
Extra wires in Corporation-street and Hammet-street	80
Taking up and laying pavement in present area	155
Extension of lighting (including taking up and laying pavement)	432
Wiring from mains to houses and transformers	300
Alteration of arc lamps	50
Extra wires for crossing roads	15
Alterations at depot	506
Legal expenses	350
Working capital	1,000
Meters	300
Sundries	222
Total	£14,000

The borough surveyor reported as follows:

I have very carefully investigated the complaints made regarding the electric light works in St. James's-street and Middle-street. I have visited the works many times and the above-named streets at all hours up to midnight, and have tried several experiments without finding a trace of vibration in either street; upon one occasion I was permitted to have the windows opened and closed at Mr Ravenhill's, i.e., Mr Showers's house, which is directly opposite the gates of the works—and it required a strain to catch the least sound of the works with all the upper windows open (I standing in the hall), and when the windows were afterwards closed not a sound could be heard, or the least vibration felt; both Mr. and Mrs Ravenhill were present with me, and neither of them could detect a sound from the works, and they also stated that they have not had to complain of any nuisance from the works the three months they have occupied the house, nor have they felt any vibration whatever. I have had the doors of the works open and shut, and have tried with a tuning fork against the glass of my watch, but have failed to detect vibration or the faintest tremor. The house adjoining the works belonging to Mr. Durham is the one exception; there a grinding noise can be heard in the rooms nearest the wall of the works, and also at the cottage in St. James's-street there is a little sound, but Mr. Yea and his wife both assured me that there was nothing to complain of, and that they had lived there some time. Therefore the question of vibration I consider has been somewhat exaggerated, but if the engines and dynamos were bedded properly on felt or rubber the sound would be considerably less; some of the timbers are also shrunk with the heat, and these assist in making a noise, but taking the works as a whole I consider the engines and machinery are running smoothly, and that there is little to complain of, especially when the doors of the works are closed. Regarding the complaint about smoke and the deposit of soot, certain alterations have been made which appears to have had the desired effect upon the latter, and the using of better coal has prevented the smoke nuisance. A steam jet has been carried up outside and through the chimney shaft about 30ft. from the base, and is connected with the boiler, so that a pressure of steam is brought to bear upon the dust when the tubes are being blown out, and which causes it to deposit at the bottom of the shaft, and here an iron door has been placed, so that the deposit can be at once removed instead of as formerly, when it would lie there until blown up the chimney by the great draught when the dampers were being manipulated. I have frequently watched the stack since the new coal has been in use, and I have seen a little brown smoke (for less than two minutes) when the lights were being put on in the town, and at other times nothing which could be called a nuisance could be seen issuing from the stack. The exhaust which is connected with the water heater should be carried in another direction; this would prevent the steam being blown into Middle-street; this is caused by the heat not doing its work properly. I have pointed this out to the manager, who has promised to get it rectified. Therefore the summary of my report is that I have not been able to detect vibration in the streets or premises near the works, neither is there a nuisance from smoke, and if the small matters suggested are attended to and the works carefully conducted, there should not be any reasonable cause of complaint.

At the last meeting of the Council, the MAYOR, in moving the adoption of the report, observed that he thought the sum of £14,000 for the purchase of the works, the providing of a working capital, etc., was an exceedingly satisfactory one. They would remember that the estimate suggested by Mr. Kapp for a similar installation with [illegible] tension came to £17,000, but now, for £14,000, by pursuing the course they had initiated, they got an installation in full working order, with all its improvements, with [illegible] dynamos, against three suggested by Mr. Kapp, and they also obtained all the plant and works.

During the discussion the following letter was read from Mr Kapp, dated July 13, accompanying a supplementary report on the lighting of Taunton by electricity:

The difference of £702 between the figures given in my unofficial letter of May 6, and the figures given in the present supplementary report, is due to the fact that, as I informed you at the time, the estimate on which my unofficial letter was based was merely an approximate estimate, and that I had not taken [illegible] on the price of the superfluous plant into account. I give this explanation now to avoid further delay in correspondence.

The following is the supplementary report alluded to:

31, Parliament-street, Westminster.

Gentlemen,—Supplementary Report on the Lighting of Taunton by Electricity.—In my report on the above subject, dated April 26, 1892, I advised you not to buy up the whole of the existing electric light undertaking in any such manner as would compel you to carry on the present system of working, but to buy only such portions of it as can be utilised when the present system of working has been changed to what is known as the three-wire system of direct supply, with auxiliary storage batteries. If, nevertheless, you determine to buy up the whole undertaking as a going concern, you can do this on the following basis: 1. You pay for those parts of the plant which I advised you to buy for the sum stated in my original report, viz., £5,250. 2. You pay for the remainder of the plant which will have to be discarded when you adopt the improved system of supply, and which hereafter I call the superfluous plant, such a sum as you are likely to realise by selling the then superfluous plant in the open market, less the amount you will lose in working the present undertaking, and less the interest on the selling price of the superfluous plant. In order to arrive at the total purchase price it is therefore necessary to make a valuation of the price which the different parts of the superfluous plant will fetch if sold in the open market, and to estimate what length of time will be required to change over from the present uneconomical system of supply to the economical system I advised you to adopt. As regards the time required for the reconstruction of the work, I consider that one year will be sufficient for this purpose, and if you commence the reconstruction immediately after completing the purchase the loss suffered during one year's working of the present plant will have to be taken into account. This loss I estimate at £350. The prices which the superfluous plant may, at the end of a year from now, be expected to realise if sold in the open market, are as follows: Countershaft and belts, £220; four arc machines, [illegible]; two alternators and accessories, £900; 70 arc lamps, [illegible]; [illegible] posts, £308; 830 insulators, £41; Elwell Parker dynamo, [illegible] dynamo, batteries, motor, switchboards, incandescent lamps and accessories, £425; total, £3,400; deduct loss on one year's working, £350, and 3½ per cent. on £3,400, £102, would make a total of £2,948; add price of useful plant as per my original report, [illegible], leaving total purchase price at £8,198.

GISBERT KAPP, M.I.C.E.

Ultimately the report of the committee was adopted by 11 votes in favour and three against.

NEW COMPANIES REGISTERED.

American Insulated Wire Company, Limited -Registered by T. T Hull, 22, Chancery lane, W C , with a capital of £75,000 in £5 shares. Object to acquire certain letters patent, patent rights, and inventions relating to improvements in the manufacture of wire, wire ropes, and cables for electric purposes and to develop and turn the same to account: as dealers in wire, wire ropes, and cables of all kinds, and as mechanical and electrical engineers, electricians, founders, machine makers, suppliers of electricity, and manufacturers of electrical apparatus. The first subscribers are:

	Shares
C. G. T. Neuman, Forster-square, Bradford	1
J. B. Atherton, Rainhill	1
W. Brigg, Hawkstone, Keighley	1
H. Neumann, 13, Claremont, Bradford	1

H. M. Brigg, Hawkstone, Keighley	1
F. J. Leslie, 15, Union court, Liverpool	1

There shall not be less than three not more than seven Directors; the first are to be elected by the signatories to the memorandum of association. Qualification not specified Remuneration to be determined by the Company in general meeting.

PROVISIONAL PATENTS, 1892.

JULY 25.

7404A. **Improvements in or relating to dynamo-electric machines and electric motors.** Sidney Howe Short, 18, Buckingham street, Strand, London (Date claimed under Patents Rule 19, April 19, 1892.)

13507. **Conduits with insulators for underground conductors for the distribution of electricity.** William Harding Scott, Gothic Works, King street, Norwich.

13541. **Improvements in the manufacture of continuous lengths of tube by electrolysis** Francis Edward Elmore, 28, Southampton buildings, Chancery lane, London

13542. **An improvement in tanks or cells for electrolysis and like purposes.** Francis Edward Elmore and Alexander Stanley Elmore, 28, Southampton buildings, Chancery-lane, London.

13543. **Improvements in electrical installations for producing alternating currents.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Siemens and Halske, Germany)

13549. **Improvements in dynamo electric machines.** Frederik Vilhelm Andersen, 40, Chancery lane, London (Complete specification.)

13557. **Improved system of electric traction for railway trains, tramways, and the like, and apparatus in connection therewith** William Phillips Thompson, 6, Lord street, Liverpool. (La Societe Anonyme pour le travail electrique des metaux, France)

13559. **An improved telephonic plant for private and domestic use** Jules Carpaux, 323, High Holborn, London. (Complete specification.)

JULY 26.

13592. **Improvements in and relating to electrical accumulators for secondary batteries.** David Young, 11 Southampton buildings, Chancery lane, London (Arthur Eastman Colgate, United States.) Complete specification)

13595. **Improvements in apparatus for varying the strength and direction of electric currents.** James Alfred Ewing and Charles George Lamb, Langdale Lodge, Cambridge

13619. **Improvements relating to electrical fire alarms and the like.** William Henry Munns, 106, Victoria chambers, Chancery lane, London. (Archibald H. Brintnell, Canada)

13639. **Improvements in acoustic telephones.** Alfred Lussack Simpson, 53, Chancery lane, London. (Complete specification.)

13648. **Improvements in electric railways.** Mark Wesley Dewey, 45, Southampton buildings, Chancery lane, London. (Complete specification)

JULY 27.

13678. **An electric combination contact bell push and pull.** William Robert Webb, 12, Shaftesbury road, Hornsey rise, London.

13683. **Improvements in the method of and apparatus for starting electric motors.** Thomas Reginald Andrews and Thomas Preece, 20, Charles street, Bradford.

13685. **Improvements relating to the saturation or impregnation of organic fibrous and cellular matter with liquids by the aid of electricity and to apparatus therefor.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Gustav Adolph Oncken, United States)

13694. **Improvements in alternate-current transformers.** Walter Claude Johnson and Thomas Boydon, 28, Southampton buildings, Chancery lane, London

13698. **Improvements in the treatment of mandrels for electrolytic deposit of metallic tubes** Francis Edward Elmore and Alexander Stanley Elmore, 28, Southampton buildings, Chancery lane, London.

13702. **Organisation and arrangement of a telephonic news transmitter.** Theodor Puskas, 19, Southampton buildings, Chancery lane, London

13718. **Improvements in conduits for electric mains and in laying the same** Henry Lewis Doulton and Charles Edward Morris, 24, Southampton buildings, Chancery-lane, London.

JULY 28.

13763. **Improvements in incandescent electric lamps.** John Bridges Lee, 3, Brick court, Temple, London.

13764. **Improvements in the construction of secondary batteries.** John Bridges Lee, 3, Brick court, Temple, London

13785. **Improvements in alternate-current electro-dynamic machines** Maurice Hutin and Maurice Leblanc, 28 Southampton buildings, Chancery-lane, London.

JULY 29.

13850. **Improvements in incandescent electric lamps and in apparatus connected therewith** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London.

13854. **Improvements relating to the application of electricity in connection with chairs, known as "dental chairs," for carrying out dental and other surgical operations** Charles Frederick Rowley, 20, High Holborn, London

JULY 30.

13856. **Improvements in electric bells** Gustav Binswanger and Herbert John Coates, 71, Queen Victoria street, London

13879. **Improvements in telephone receivers** Ernest Walter Lawson Harrison and Sydney Murray, 53, Arcade chambers, St. Mary's Gate, Manchester

13894. **Improvements in submarine telegraph cables.** William Henry Preece 28, Southampton buildings, Chancery lane, London

13919. **Improvement in incandescent electric lamps** Elihu Thomson, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

13920. **Improvements in methods of regulating electrically-driven mechanism and apparatus for putting the same into operation.** Walter H Knight and W. [illegible] Potter, 45, Southampton buildings, Chancery lane, London (Complete specification)

SPECIFICATIONS PUBLISHED.

1891.

5790. **Incandescent electric lamps** Boehm and Bailey

11447. **Electric arc lamps.** Norman and Payne.

11891. **Telephone switch devices.** Thompson. (Dietz.)

NOTES.

Salford.—Tenders may be invited shortly for Salford central installation.

Personal.—Mr. H. D. Cheever, of the Okonite Company, is in England on business.

West Hartlepool.—The tenders for Hartlepool co-operative stores must be in by to-night (Friday).

Wigan.—The Wigan Town Council have resolved to ask for extension of their provisional order for two years.

Burnley.—Tenders will soon be required for machinery at Burnley; the tenders for the buildings are required by the 30th inst.

Book Received.—"Chemical Theory for Beginners," by Leonard Dobbin, Ph.D., and James Walker, Ph.D., D.Sc. Published by Macmillan and Co.; price 2s. 6d.

Belt Slipping.—To prevent slipping, an American company now produces belts faced with corrugated rubber on the inside, which runs over a pulley of the same nature.

Electric Traction.—A scheme, it is stated, is being brought forward in America for the establishment of an electric power and traction system involving the erection of engines for a total of 100,000 h.p.

East Sussex.—A committee has been appointed to go into the question of electric light for the East Sussex County Hall. The committee consists of Mr. Curry, Major Edwardes, and Mr. Farncombe.

American Stock.—Anyone interested in stocks and shares would be pleased to receive a copy of the circular of Whittaker and Hodgman, of St. Louis, showing a classified list of securities with information.

Fireman's Exhibition.—A fireman's exhibition was opened on Tuesday at the Royal Aquarium, Westminster, and will remain open until the end of the month. Some interesting alarm arrangements are shown.

Bournemouth.—The General Purposes Committee of the Bournemouth Town Council have referred to the Lighting Committee the report of Prof. Kennedy as to the lighting of the pier and pleasure grounds by electricity.

Electric Crane. — Tenders are required by the Manchester Gas Committee for an electric crane at their electric light station. The tenders are to be sent, in by August 19, to Mr. C. Nickson at the Manchester Town Hall.

Hat Brushers.—The Crocker-Wheeler motors are now used for hat polishing. The hat is mounted on a block on a spindle and, whizz! the polishing is done in an instant. The ironing can be done by electricity also, and what more could you want—except a new hat!

Chicago.—Sir H. Trueman Wood presents his report on the Chicago Exhibition in the *Journal* of the Society of Arts this week. They have not yet all the power they want for the dynamos, and would like one or two 500-h.p. engines. Combined plants would also be acceptable.

Electrical Works.—If anyone knows of a good and convenient site (with or without shops) for establishment of heavy electrical engineering works in or near London, it would be interesting to hear of such, as the progress of the trade has caused one or two such enquiries to reach our office.

Durham College, Newcastle.—Complete courses in mechanical, marine, and electrical engineering are now organised in the Durham School of Science, Newcastle-on-Tyne, and in order that real practical experience can be obtained, arrangements are made for pupils to work part of the time during vacation in some of the large engineering works in the neighbourhood.

Pontypool.—Application has been made to the Board of Trade by the Pontypool Electric Light and Power Company, Club-chambers, Pontypool, for a license to supply electricity within the district of the Local Board. Messrs. Sherwood and Co., 7, Great George-street, are the London agents.

Wigan Tramways.—We hope that the reconstruction of the Wigan tramways, as at one time proposed, will embody the introduction of electric traction. It is a good chance, and if possible financially, should be taken. Mr. Heaton has just been engaged as engineer for the reconstruction.

Heckmondwike.—Mr. F. W. Reuss, writing to the Dewsbury paper, suggests the use of the continual flow of water in Heckmondwike, power being taken at Dunford Bridge by cables along the land of the Water Works Board. Batley, he says, might also obtain power in the same way.

Waterford.—The Bray Township Commissioners have written to Waterford to say "the light is very satisfactory." The borough treasurer of Kilkenny writes urging Waterford to follow in the footsteps of St. Pancras, Dublin, and other places, keeping the contract for the lighting in their own hands.

Brooks Cables.—We are very pleased to learn that the Brooks oil system of cables is to be used at Chatham for the high-tension alternating underground mains for the Rochester, Chatham, and District Electric Lighting Company. The Brooks system has always given satisfaction and deserves further extension.

Dundee.—At the meeting of the Electric Lighting Committee of the Dundee Gas Commission held last week, the following names were selected for recommendation to the Board for the post of electrical engineer: Mr. W. H. Brownlee, Glasgow; Mr. Charles Yeaman, Liverpool; Mr. A. F. Proctor, Newcastle-on-Tyne; Mr. A. B. Gill, London.

Grimsby.—At the Grimsby Town Council meeting last week it was resolved to authorise the Lighting Committee to take into consideration the desirability of lighting the important thoroughfares, squares, and markets in the borough with the electric light, and to obtain statistics and the probable cost, and to report thereon. It was explained by Mr. Connell that no money would be spent; it was simply a matter of enquiry.

Electric Railway.—It is announced that the New York, New Haven, and Hartford Railroad is constructing a four-track line, of which the two inside tracks are to be equipped for electricity, instead of steam, for both passenger and quick goods traffic. The line is 74 miles long, and the distance is to be covered in 60 minutes. An overhead wire system is to be used. The central track will be fenced in, and no level crossings will be allowed.

Chesterfield.—At the quarterly meeting of the Chesterfield Town Council on Tuesday the Mayor moved the appointment of a committee to consider the cost and advisability of lighting the town with electricity. He said the gas they used was not only high priced, but bad in quality. He thought the Corporation should obtain a provisional order, and carry out the lighting to prevent another monopoly. The motion was carried.

Alternating Currents.—By the courtesy of the editor of the N.Y. *Electrical Review* we have received advanced proofs of an article entitled "Note on Some Experiments with Alternating Currents," read at the American Institute of Electrical Engineers at Chicago by Dr. Louis Duncan.

assisted by Mr. E. R. Carichoff and Messrs. R. H. and G. E. Hutton. Although very interesting, it is impossible, by reason of pressure on our space, to give it this week.

Glasgow.—The Sub-Committee on Contracts of the Gas and Electric Lighting Committee of Glasgow Town Council recommended the Town Council, at their meeting on Thursday, to accept the offer of Messrs. Easton and Anderson, for the engines for the new electric lighting station, at a price of £1,108; and the offers of the Brush Electric Lighting Plant Company for the dynamos and the arc lamps, the contract price for the former being £1,510, and for the latter, £7. 13s. 8d. per lamp.

Barking Cars.—On the eve of renewal of the contract for the Barking road cars the North Metropolitan suddenly threw up the contract, and this just after putting the line into repair, a matter the traction company have been urging for months as causing breakdowns; and in proof, no stoppages have occurred during the last fortnight since the repairs. The affair affects both the traction company and the Electrical Power Storage Company, and will, we fear, form the subject of a lawsuit.

Cardiff.—A lengthy report, which had previously been presented to the Cardiff Lighting and Electric Committee by the sub-committee and accepted, was submitted to the Council on Tuesday as incorporated in the minutes of the meetings of the committee. The report stated in detail the result of the investigations of the sub-committee into the question of the electric lighting of the borough, the approximate cost of which to commence was estimated at between £25,000 and £30,000. The minutes were passed.

South African Journal.—We have received the first number of the *British and South African Export Journal* (53, Carter-lane, Doctor's-commons). It is a bright, well-written, practical journal, and now that Africa is growing in importance, and more particularly at this moment when Kimberley Exhibition is about to be opened, this journal should receive a warm welcome from British manufacturers. The price is sixpence, and it is illustrated, the first number containing a photogravure of the celebrated Royal Mail Cape steamer "Scot."

Liege.—The determination has been taken by the College Echevinal of Liége to establish a central electric station, and M. Mahiels, engineer-in-chief to the town, has been instructed to draw up a scheme. The project is expected to be drawn up by October, and the tenders may be accepted, if nothing interferes, before the end of the year. It is thought that a concession will be given with power of repurchase on reduced tariff year by year. The scheme is being the more forced forward as several private persons are thinking of putting up small stations for the supply of separate blocks of buildings.

City of London Lighting.—The annual meeting of the City of London Electric Light Company will be held early next month, and we believe the chairman's speech will contain some extremely interesting and inspiriting reading. Electrical engineers will await this event with much interest, although no doubt the account of solid results financially will be better next year. The company has been doing very good work lately, and credit is due to the directors, the contractors, and to the energetic manager, Mr. David Cook, who have all had an immense amount of hard work to do during the past year.

Bilston Market Hall.—This new market hall, which was formally opened on the 9th inst. by Sir Alfred Hickman, M.P., is noteworthy in being entirely dependent upon electricity for lighting. The interior is lighted by three 2,000-c.p. arc lights and by 74 incandescent lamps of 16 c.p. in the closed stalls, offices, etc., and the exterior by two 2,000-c.p. arc lamps. The whole of the plant, including loco. boiler, engine, and dynamo, has been supplied and erected by the Brush Electrical Engineering Company, Limited, through their Manchester branch, to the requirements of the township surveyor, Mr. C. L. N. Wilson.

Cheltenham.—The arrangement of the electric lighting does not seem to be going on very fast at Cheltenham. At the last Town Council meeting the Electric Lighting Committee reported that they had requested the town clerk to write to the Board of Trade, forwarding copies of the borough surveyor's and Prof. Ayrton's reports on electric lighting in the borough, explaining the present position of the matter, and giving the reason why greater progress in it had not been made. The question of another interview with Prof. Ayrton was adjourned for further consideration. These minutes were adopted without discussion.

Croydon.—As we mentioned last week, the Croydon Corporation have decided to keep the option of ownership of the electric lighting. They now invite offers for transfer of the powers with option of repurchase. Tenders must state the terms and the system proposed. Tenders must be sent in to Mr. C. M. Elborough, town clerk, Town Hall, Croydon, by the 15th of September. The town is a large one—much larger than many of the other towns now going in for the light—and is worth careful attention from our representative engineers. Finance, we suppose, will have to step in and have its way before the station becomes an accomplished fact.

Blackpool.—The Blackpool Corporation have decided to adopt the high-tension alternating-current system of electric lighting, and active preparations are being made for an early commencement of the works. The appointment of Mr. John Hesketh, formerly with the Newcastle Electric Supply Company, as resident electrical engineer, has been confirmed by the Council, and the committee authorised to make application to the Local Government Board for sanction to borrow £26,000 for electric lighting purposes. The contract for the necessary machinery has been let provisionally to Messrs. Hammond and Co., of London.

Nelson.—The arrangements for electric light at Nelson (Lancs.) have come to a practical point. Tenders have been received and reduced by consideration of the Gas Committee to one—that of Mr. Barton being recommended for acceptance. The Local Government Board have sent in their approval of the Corporation's request for power to borrow £3,920. The committee have been given full authority to deal with the tenders and put the work in hand immediately. It is a small and useful installation, and care should be taken by the engineer in charge of it that it turn out thoroughly efficient, as its success may lead to a number of other small stations in the populous districts of the North.

Owens College.—A special course has been arranged at Owens College, Manchester, on the technical applications of electricity. A dynamo-house has recently been built in connection with the physical laboratory, containing a 7-h.p. Otto gas engine, two direct and two alternate current dynamo machines, specially constructed for purposes of instruction. In the laboratory full instruction is given in electric and magnetic measurements, testing of dynamos. If a student goes practically through this course he ought to be able to calibrate instruments and test dynamos or aid in this work, and if he can do this he can usually find a place of some kind in an electrical works at once. If he could further make a decent working drawing (how many

students can ?) he would really be worth paying on entering the shop, which is more than can be said for many technical students for a year or two after leaving the electrical "lab."

Blackburn.—At the quarterly meeting of the Blackburn Town Council last week it was resolved, on the motion of Councillor Thompson, that application be made to the Local Government Board, in pursuance of the provisions of the Electric Lighting Acts, and of the Blackburn Electric Lighting Order, 1890, for the sanction to the borrowing by the Corporation of the sum of £50,000 for the purpose of laying down an electric lighting installation in the borough, and for all necessary works in connection therewith. The Council also ordered that Mr. Barton, of Blackburn, in conjunction with the borough engineer, be instructed to prepare estimates, plans, and specifications of proposed electric lighting plant and works. Also that it be referred to the Gas Sub-Committee to select a suitable site for the electric lighting works, and to ascertain upon what terms Mr. Barton would act as engineer to the Corporation in fixing the electric lighting plant.

St. Pancras.—Tenders are required by the Vestry of St. Pancras for the following: (1) Supplying about 50 cast-iron columns for arc lamps; (2) supplying, fixing, and setting to work about 50 arc lamps, to be worked 11 in series by existing high-tension machines, drawing cables through pipes, providing switches, and making all connections; (3) supplying high-tension cables; (4) supplying cast-iron pipes for cables; (5) erecting the cast-iron columns, laying cast-iron pipes, constructing manholes with cast-iron covers. Drawings, showing the positions of the arc lamps and the constructing of the manholes, covers, pipes, etc., can be seen at the offices of Prof. Henry Robinson, C.E., 13, Victoria-street, Westminster, where copies of the several specifications can be obtained on payment of 2s. each. Tenders to be sent to Mr. A. E. Pycraft, chief clerk, Electricity Department, Vestry Hall, Pancras-road, N.W., by 22nd inst.

Accrington.—The electric light question is not dropped at Accrington, as it looked a while ago. Councillor Riley at the meeting last week moved that the Legal and Parliamentary Committee submit a full report with respect to the establishment of a central station. The provisional order expires during this month, and it seemed that a private company intended to apply for powers to supply the electric light not only for Accrington, but for the whole of the surrounding district. The ratepayers, he said, might find that their £500 had been spent to no purpose, and at some future time they might be called upon to buy out another gigantic monopoly. If the Corporation intended to adopt the electric light they should do it at once, or make way for someone else. Councillor Hardacre said he was informed that a number of local gentlemen had the matter before them, and intended, if the Corporation did not move, to take the matter up. The Mayor mentioned that they had some idea of utilising 200 h.p. from the destructors. The motion was carried.

Whitehaven.— The chairman of the Whitehaven Trustee Board referred at the last meeting to the proposed adoption of the electric light, and said that a letter had been received asking for certain information which it would be necessary for the Local Government Board to have before they could sanction the borrowing of the money. That information would be sent at once, and everything possible was being done to push the scheme forward. Mr. Robinson enquired whether any estimate had been made as to the number of people who would use the electric light when it was obtained. The chairman replied that there was an estimate in Dr. Hopkinson's report, but this was merely a guess, founded upon similar places where the electric light had been put down. As soon as certain information had been received from Dr. Hopkinson in regard to the probable price the electric light would be supplied at, efforts would be made to ascertain how many tradesmen and others would adopt it. Mr. Bowman thought this should have been done before the resolution was passed. A good feeling, however, is evidently present in the town.

Bedford.—The Corporation of Bedford, having resolved not to proceed themselves with the introduction of electric lighting into the borough, have had a special meeting to consider an application from the Bedford Electric Light Company for a transfer to them of the Board of Trade's provisional order, with a view to their undertaking the task. After a lengthy discussion, it was resolved to ask the Board of Trade's sanction to the transfer. In the meantime Alderman Hurst has withdrawn his name from the Gas and Electric Light Committee. During the recent discussions several allusions have been made to handsome profits accruing to the shareholders in the gas company, and the members of the Council who are also connected with the latter company are accused of opposing the introduction of the electric light from personal motives. The transfer to the Bedford Company certainly seems the best way of dealing with the matter, and we hope the project will not again fall through. There is, in Waterloo-place, an Electric Association—more or less moribund, we are afraid. But it is exactly in such crises that Bedford and Waterford are passing through that an association such as this might reasonably be expected to throw its weight against the machinations of the gas interest.

Hastings.—At the meeting of the Hastings Town Council last Friday the Public Lighting Committee reported that they have had under consideration the matter of the desirability of extending the electric light on the sea front. They had been in communication with the Hastings and St. Leonards-on Sea Electric Light Company on the subject, and had ascertained that the company were prepared to enter into a contract with the Corporation for a period of three years, by means of 51 arc lamps placed 80 yards apart (instead of 100 yards, the distance between existing electric lamps), the whole of the lamps to be lighted from sunset to 12 midnight, and after that hour each alternate lamp to be extinguished, and the other lamps to be kept alight till sunrise, the company undertaking to maintain a steady light, free from extinctions, at £25 per lamp per annum, the contract to commence as soon as the company had made the necessary additions to their machinery and mains. The committee were informed this machinery would be of the latest and most improved type, and duplicated to prevent any failure in the supply. The committee had fully discussed this offer, and had received from the borough surveyor a report on the subject. They recommended that the offer should be accepted. But it was decided to withdraw the matter for further consideration.

Wolverhampton.—At the quarterly meeting of the Wolverhampton Town Council on Monday, the Mayor moved the adoption of the Lighting Committee's report relative to the supply of electricity within the borough and the appointment of a special committee to advertise for tenders for the construction of the necessary works. He pointed out that the Corporation were compelled to take up the question of supplying the electric light in order to prevent a company securing a monopoly. Unfortunately they had experienced the result of the monopoly enjoyed by the gas company, and it was the duty of the Town Council to prevent another company exercising similar powers in

regard to the electric light. A company had been formed to supply electric light in the town, and unless the Town Council had applied promptly for a provisional order the privilege would have been secured by some other body. The superiority of the electric light over gas was admitted, and as many corporations had installed the light in their boroughs, he hoped Wolverhampton would follow their example. Alderman W. H. Jones, in seconding the resolution, said it was intended to light only a small area at first, and that it was the opinion of experts that in a short time the electric light could be supplied at the same price as gas. After a brief discussion, the resolution was agreed to unanimously.

Kimberley Exhibition.—Those who don't intend to exhibit at Chicago should certainly consider Kimberley. The exhibition at Kimberley is to be opened on September 8 by Sir Henry Brougham Loch, K.C.M.G., governor of the Cape of Good Hope. It is as well to remember that Cape of Good Hope is in Britain—Greater Britain—and is one of the most important of the United British States. It is not so very far away—14 days—and it takes seven days, even now, very often, to go from New York to 'Frisco. Our far west is in the Cape, and the development given to the original Far West must and will be given to the Cape and its upper dependencies, now becoming more and more important. Kimberley will be the starting point for much opening up of new work. The best means, the best methods should be used, and these are now generally electrical. Messrs. Mather and Platt are now undertaking the exhibition installation. The machinery will consist of three arc-light machines of the "Manchester" type, each of 10 amperes at 900 volts, to supply 18 arc lamps in series. Brockie-Pell lamps will be used, 36 in number, in the grounds, on sectional standards The building will be lighted by 700 16 c.p. lamps, supplied by three low-tension "Manchester" dynamos, giving each 130 amperes at 100 volts. A 100-ampere search light will be supplied by Messrs. Crompton. An electric tramcar will be run by Messrs. Gibson Bros. between the exhibition gardens and the Central Hotel at a charge of 3d. Messrs. Woodhouse and Rawson intend to have an exhibit, and there will be a good assortment of mining machinery.

Barnsley.—The electric light is again relegated to the future in Barnsley, for the Town Council has not risen to the occasion, and the amendment to the resolution to go on received most support. The meeting was held on Tuesday evening, the Park and Lighting Committee recommending: (1) That the electric light be installed on a site in Beckett-square, at an estimated cost of £18,382, but that at present only £13,332 be expended; (2) that Mr. A. Bromley Holmes be appointed electrical engineer, and that he be instructed to prepare all plans and specifications, and estimates of the electrical plant; and that the borough surveyor be instructed to prepare the plans, specifications, and estimates of the requisite buildings, and that such plans and estimates be submitted to the committee as early as practicable; and (3) that application be made by the Council to the Local Government Board for their sanction to borrow the said sum of £18,382. The Mayor moved the adoption of the report, and Alderman Wray seconded, saying something should be done to break the neck of the gas monopoly. Gas, which would cost £13 or £14 a year to a tradesman in Wakefield and other towns, would cost £22 or £20 in Barnsley, which was in effect a rate at 2s. in the pound on a tradesman rated at £70 a year; and he suggested that the present rating of the town had been made higher than it ought to have been simply to choke or keep back this scheme. Alderman Marsden, as chairman of the Finance Committee, deprecated this statement, and asked if it were thought they would put upon the poor of the town a rate in order to support a private company against the electric light. Dr. Halton moved that the matter be adjourned 12 months, and this was carried, only the committee voting for the resolution.

Oldham.—A Local Government enquiry was held last Friday before Colonel John Hasted, R.E., at Oldham, with reference to powers for borrowing £40,000 for electric lighting. The town clerk explained that the Corporation had acquired a plot of land in 1887 and a provisional order in 1890. They retained Prof Kennedy in February this year as electrical engineer, and he had drawn up a scheme for simultaneous lighting at first of 2,500 8-c.p. lamps on the two-wire system of bare wire mains. His estimate was £21,000, and the Corporation asked for £40,000 in order to be able to extend. A canvass has been made, and, with the Municipal Buildings, nearly 2,000 lamps will be at once taken up. Prof. Kennedy explained the details and cost. He proposed four 60-h.p. direct-driven sets, and others of 100 h.p. The batteries to be used for electric lighting purposes in the daytime would, he thought, be sufficient for a long time to come. They would keep 200 lamps alight for eight hours. The scheme was so arranged that the two-wire system could be changed to three wire if the demand required it, without interference with the streets, and the same engines and dynamos could be used. The question of laying the mains was one of great importance, and he first advised the modified adoption of the plan he had adopted in London, and which had proved very successful—laying the wires in a concrete trench under the pavement. In one or two places—at several crossings—insulated wires would be enclosed in cast-iron tubes. The cost he estimated as follows: The plant, including everything stationary, £8,800; the mains, £5,600; the buildings, £6,000; the meters, £600. He thought those prices were full. By the advice of the inspector, the cost of site—£4,000—was included in the estimated total cost of £26,000. There was no opposition.

Brussels.—At the discussion upon the adoption of electric lighting at Brussels some explanation was given as to the alleged raising by 40 per cent. of price of charge of Messrs. Crompton's estimate by the committee. M. Janssen stated that the various tenderers had taken different figures as to depreciation, cost of carbons, etc., and these had been all brought to one scale. M. Bede gave a long discourse, dealing with the technical and financial points of the scheme. The city, he said, had offered an installation of 10,000 lamps, with power of extension to 20,000 lamps. Of eight projects presented choice lay between that of the India Rubber Company (closest to the desires of the town) and scheme No. 2 of Schückert and Co. (the lowest) The India Rubber Company's tender was for 3,762,000f., and Schuckert's (No 2) 2,803,000f. The difference, said M. Bede, was still greater on examination, as the first would barely suffice for the 10,000 lamps, while Schückert's would supply over 13,000. So while paying 25 per cent. less, the town would obtain 30 per cent. more light. Schuckert's scheme was therefore only 58 per cent. of the cost of the other. The one company, though honourably connected, had carried out no central scheme, while the other had. The 16-c.p. lamp in Schuckert's installation would cost 1·56 centimes per hour, as against 2·40 centimes with the other. Why had the committee given the preference to the India Rubber Company? For thre emotives: because Schuckert's propose to use accumulators on too large a scale; also the I.R. mains are considered the better, both for material and on account of

facility of changing, so that it would be possible to start at once with a less costly station. M. Bède criticised all these motives. Accumulators were necessary to supply the outlying quarters; indiarubber was good for indoors, as Mr. Preece said in 1887, but not so good for outdoor underground work (though this applies to pure, not vulcanised, indiarubber). The I.R. cable supplied for the Theatre de la Monnaie had already cost in four years 8,700f. for repair. Besides, drawn-out cables lost their value. Suppose it was only half, this would make 2,042,000f. added to 2,447,000f. to-day—*i.e.*, 4,487,000 against 2,803,000; in other words to avoid paying 356,000f. extra now, they would have to pay 1,684,000f. extra later on—to economise 10,000f. a year interest, etc., now, they would pay 144,000f. a year for ever. The question was not one of first cost alone, but of maintenance, and M. Bède ended by demanding that the decision should be adjourned till October. M. Janssen wondered that M. Bède did not propose the adoption of M.M. Schückert's scheme. The discussion was adjourned. At their last meeting, after a long discussion, the Municipal Council decided unanimously (excepting M. Bède) to grant the concession to the India Rubber Company.

Melbourne Boilers.—"One Who Knows" writes to the *Building and Engineering Journal*, of Melbourne, with reference to the boiler tender for the electric light station: "The recent decision of the City Council as regards boilers to be used in connection with the electric lighting of the city has attracted considerable attention, and has been the subject of strongly adverse comment. The facts of the case seem to be as follows: Tenders were called for the supply of four water-tube boilers, each of 250 h.p., and capable of evaporating 7,300 gallons of water per minute. The usual conditions of tender and deposit were present, and amongst these it was directed that tenderers must be in attendance at the time of opening tenders. On enquiry as to when tenders were to be opened, that information could not be obtained; but after some days' delay the assurance was given that written intimation would be forwarded, so that tenderers might be present as directed. It is sufficient to say that the promised intimation was not sent. This and other minor irregularities might have passed unnoticed, had not the final selection of boilers by the Council lent them significance. The boilers accepted by the Council are those known as the 'Babcock and Wilcox,' and from the results of numerous and reliable tests, which have been frequently published, it will be seen that whatever governed the Council in their selection, it was certainly not economy. From these tests it will be seen that the 'Mills patent boiler,' which I understand was offered in this instance, has the following claims over the Babcock and Wilcox boiler: 35½ per cent. in economy, 43 per cent. more duty, and 40 per cent. greater efficiency. The water evaporated per pound of fuel by the former is shown as 9·39lb., by the latter 6·9lb., and it certainly cannot be questioned which is the more economical steam generator of the two. While the Babcock and Wilcox boiler has frequently entailed fines on its users for creating a smoke nuisance, the Mills boiler secures an almost entire absence of this disagreeable adjunct. All the foregoing information, no doubt, accompanied the tenders sent in by the agents for the Mills Patent Boiler Company, and also the published reports of the highest boiler experts in England, showing the superiority of the Mills over the Babcock boiler. The action of the Council, therefore, in rejecting the superior and economical steam generator in favour of its proved inferior is a matter worthy of the consideration of the ratepayers who find the money and look to their representatives on the Council for its proper application." Their correspondent concludes: "This is by no means the first instance in which the result of public competition has been decidedly the unexpected, and unless tenderers are encouraged in the belief that the merits of the article offered will be considered in determining selection, we shall arrive at a point at which it will be considered waste of time and money to compete for municipal work."

Dublin.—Last Friday the official tests of the Dublin electric light installation were commenced, under the direct supervision of Mr. Robert Hammond, of Hammond and Co., who have carried out the contract; Mr. E. Manville, electrical engineer to the Corporation; and Mr. Spencer Harty, city surveyor. The following engineers were also present: Mr. Charles J. Hall, co-patentee of the Lowrie-Hall system in use in Dublin; Mr. J. W. Chisholm and Mr. H. Dickenson, of Messrs. Hammond and Co.; Mr. M. Ruddle, on behalf of the Corporation; and Mr. Porte and Mr. Haslam, of the Electrical Engineering Company of Ireland. The members of the Electric Lighting Committee of the Corporation visited the works during the evening, and evinced the greatest interest in the running of the plant. They were afterwards entertained by Mr. Hammond in the large offices. The *Irish Times* gives the following account of the ceremony: "The magnificent alternating-current dynamos worked splendidly, and it must have been particularly gratifying to Mr. Hammond and Mr. Hall to hear the numerous favourable opinions that were expressed of their work by the engineers present. Messrs. Hammond and Hall were hard at work during the afternoon, evening, and night, attired like ordinary workmen, controlling the entire machinery with marked ability and precision, while Mr. G. W. S. Hawes, the young Dublin secretary of Messrs. Hammond and Co., was assiduously engaged for several hours in explaining the working of the plant to a succession of privileged visitors. There are three compound vertical engines working dynamos to supply the arc lamps in the streets, and three compound horizontal engines for private lighting purposes, these having been manufactured by Messrs. Victor Coates and Co., of the Lagan Foundry, Belfast. The dynamos for the private lighting are alternators, while those supplying the streets are Brush arc light dynamos. The assistants attending them wear india-rubber gloves, which effectually protect them in their dangerous occupation. As early as four o'clock in the evening the lamps on the circuit embracing Sackville-street, Westmoreland-street, Dame-street, and Grafton-street were illuminated, but in the clear daylight its effect was scarcely apparent. At nightfall a fine opportunity for observing the power of the new illuminant was afforded to thousands of the citizens who thronged the streets, and evidently much admired the light. In order to make the test more effective the gas lamps throughout the circuits operated on were left unlighted, and between eight and nine o'clock considerable disappointment was felt at the circumstance that while some of the lamps were giving a brilliant light others in their immediate vicinity were either flickering, or, having shown some signs of life, had gone suddenly out. The public were, of course, unaware of the cause of this, which arose from the circumstance that the engineers in Fleet-street were testing the circuits separately, and it appears that while these circuits are controlled from the central works, each individual lamp is regulated from the box at its base. About nine o'clock a second engine supplying the arc lamps in the streets was set to work, and the effect in the thoroughfares was quickly apparent." The lighting seems to have been a success, save that one of the machines failed to stand the twelve hours' test, the armature having given way. A further test takes place this week.

STEAM AND GAS ENGINES AT THE ELECTRICAL EXHIBITION.

Although the Electrical Exhibition has been closed it is none the less necessary that we should place on record some descriptions, with illustrations, of the steam and gas engines there exhibited, to some of which we referred in the article in our impression of July 1st (p. 31).

We may commence with the very fine triple-expansion engine, of which we have already given a few particulars. The engraving we now publish (Fig 1) is a front view of this engine taken from a position which shows nearly all the motion parts with the exception of the governors. The high-pressure cylinder is 12in. in diameter. This receives steam at 160lb. pressure per square inch, and exhausts into the intermediate cylinder, which is 18¾in. in diameter, and in its turn exhausts into the low-pressure cylinder, which is 30in. in diameter. All the pistons have a stroke of 18in., and when running at its full speed of 140 revolutions per minute the engine indicates 350 h p. The cranks are placed equidistant, the intermediate and low-pressure cranks following the high-pressure in order, and therefore each 120deg after the high pressure and after the intermediate cranks respectively. The high-pressure main valve is operated by one eccentric, and the cut-off valve, on Paxman's system, is operated by a pair of eccentrics through the medium of a slotted link, the position of which is controlled by the governor. The latter is placed behind the high-pressure cylinder, and is not seen in the engraving. One of the expansion valve eccentrics has a longer stroke than the other, and thus, if it be controlling the movement of the valve, cuts off steam earlier than when the link is pulled over, so that the valve is moved by the other eccentric.

The engine is fitted with a flywheel 6ft. in diameter, and the ground space covered is only 10ft. 6in. by 6ft. 9in., this width including that of the platform, which is 2ft. 9in. above the floor. The height of the engine from the floor to the top of the cylinders is 11ft., and above this stand the steam supply valve operated by a hand-wheel and bevel, gear shown in the engraving, and the sight-feed steam lubricators.

The engine is very much of the marine type, with semi A frame and turned wrought-iron columns supporting the cylinders. Every part of the engine is lubricated from fixed oil-boxes, the engine being provided with very ample bearing surfaces of all forms, and in every respect it is designed for running at full power for long periods. It is expected to develop an indicated horse-power for about 16lb. of steam. Of the central station multipolar dynamo connected directly to the crankshaft, and made by Messrs. Johnson and Phillips, we need say nothing here, as we described this machine in our impression for the 15th April last.

We may now turn to one of the smallest engines exhibited at work in the recent exhibition—namely, the Case high speed engine—illustrated in our engravings by Figs. 2 and 3. In this engine the cylinder is within a semi-rotating block, so that it may be called an oscillating cylinder; instead, however, of oscillating upon small trunnions in the manner commonly adopted, the ends of the whole block, with the diameter of the length of the cylinder, form the trunnions. The bearing surfaces are, therefore, so large that wear must necessarily be extremely slow. In this application, moreover, the cylinder is steam balanced, so that the pressure upon these surfaces is exceedingly small. The upper end of the cylinder (see Fig. 2) is closed to the steam only by the circular seat in which the cylinder block oscillates. On the lower end of the cylinder, to which is attached a long guide tube for the piston-rod, the same steam balancing is effected by the use of steam within a chamber between the circular seat and the cylinder block. The steam-ports are arranged in the cylinder block and circular seats, and steam is admitted and exhausted by the oscillation of the cylinder. In Figs. 2 and 3 the engine is shown as controlled by a governor which moves a throttle valve, but the engine is made as shown in Fig. 4, with an automatic cut-off valve operated by an eccentric, the position of which is controlled by a flywheel governor. The cut-off valve is a slightly tapered plug, closing or opening the steam port

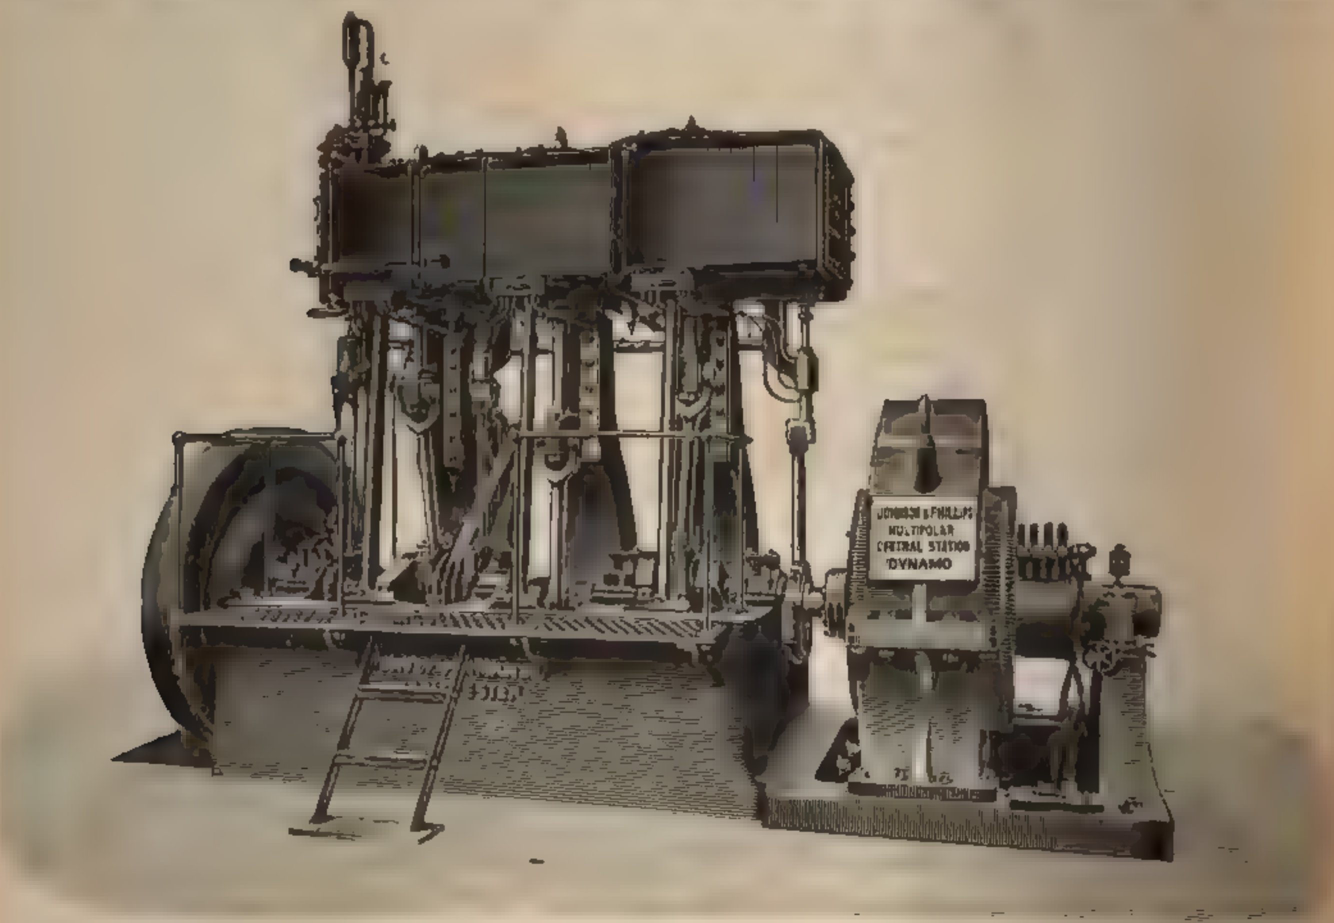

FIG. 1.

The exhaust remains unaffected by the cut-off. The diagrams, Figs. 5 and 6, are taken from one of

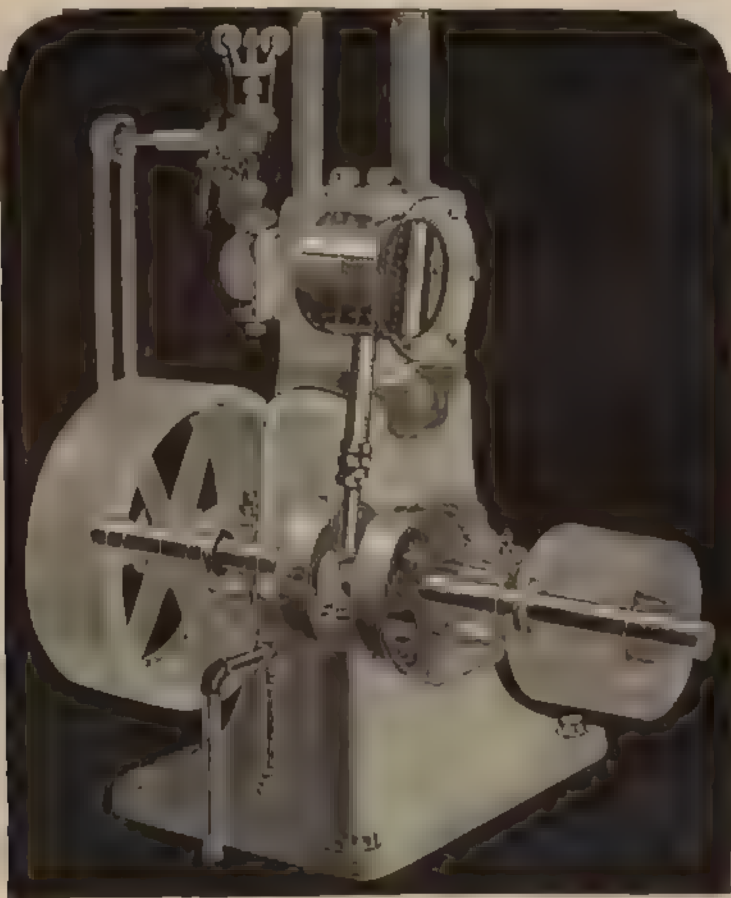

Fig. 2.

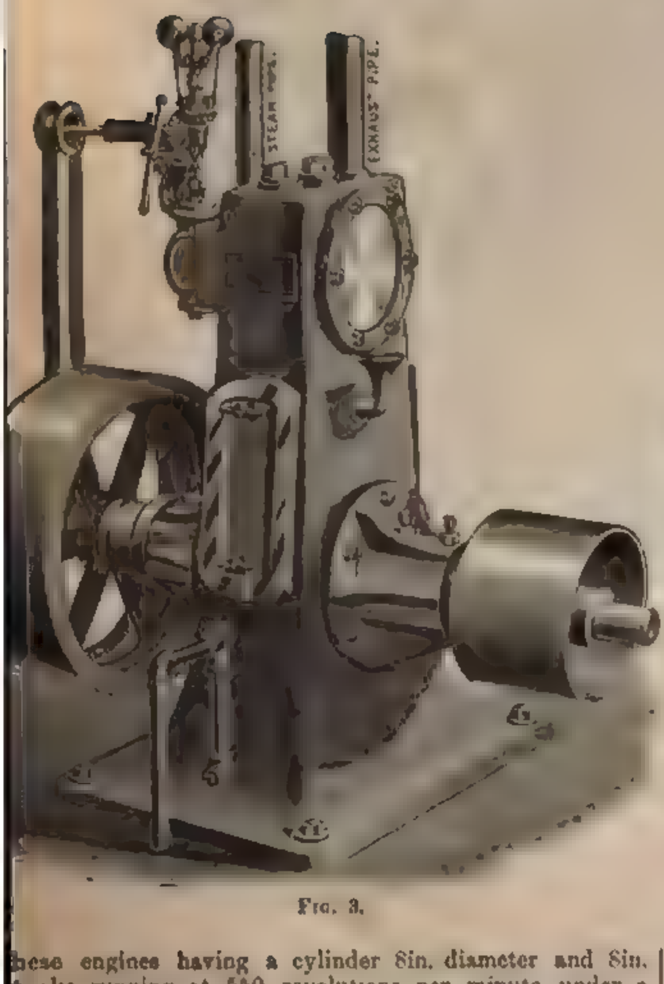

Fig. 3.

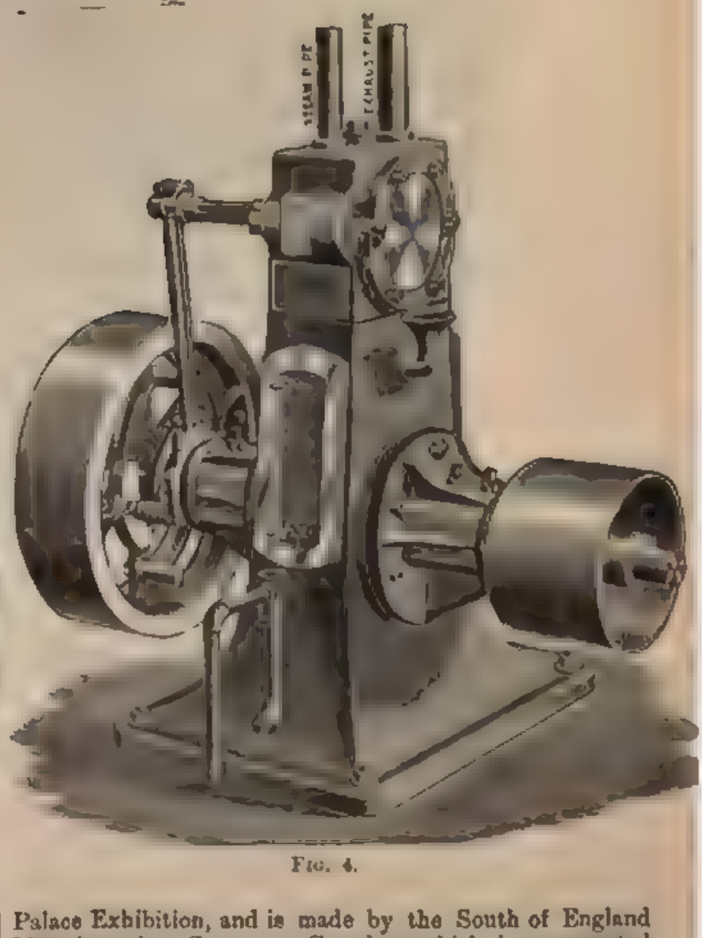

Fig. 4.

these engines having a cylinder 8in. diameter and 8in. stroke running at 550 revolutions per minute under a steam pressure of 120lb. per square inch. This little engine attracted a great deal of attention at the Crystal Palace Exhibition, and is made by the South of England Manufacturing Company, Croydon, which is represented

in London by Messrs. Charles Churchill and Co., of Cross-street, Finsbury. We may mention that the engine is made in several sizes and in several forms—namely, as a

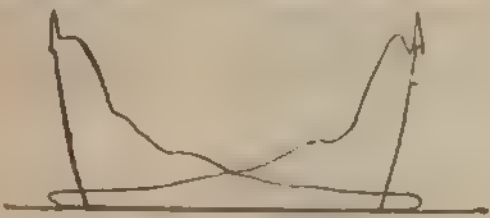

Fig. 5.

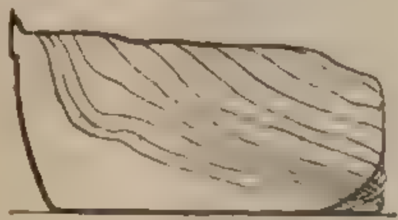

Fig. 6.

wall engine, as a launch or marine engine, as a hanger engine, and as a reversible pedestal engine.

ALTERNATE-CURRENT DYNAMOS.

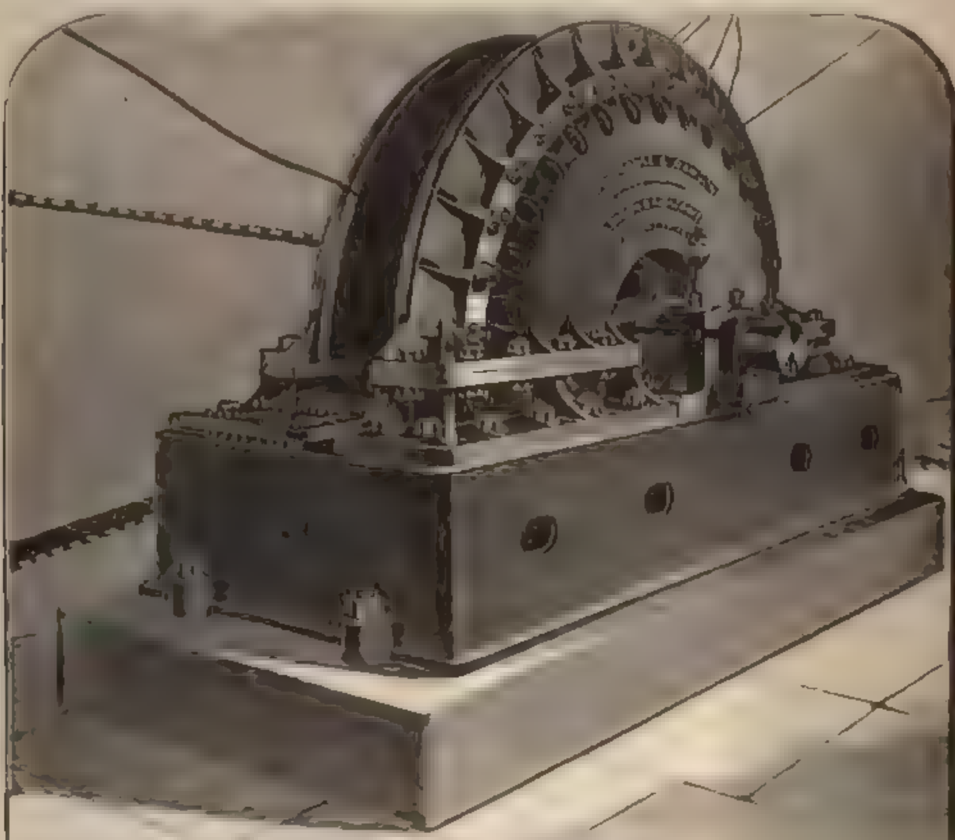
BY R. W. WEEKES, WHIT SCH.

Messrs. Woodhouse and Rawson.—The block of the Kingdon inductor made by this firm does not give much idea of the design and principles of action of this alternator. The machine belongs to the class of alternators

lately at the Crystal Palace. In fact, the design is still being altered, and for that reason the firm do not wish to publish many actual details.

The iron parts are all built up of charcoal-iron plates. The outer ring, which has a number of projections on the inside, forms the core for both the armature and exciting coils, the alternate projections being the armature cores. The exciting coils are placed round the others, and so connected as to give north and south poles alternatively. In the machine exhibited at the Crystal Palace the armature cores were considerably smaller than the magnet cores, and not equal, as shown in the sketches. In building up the segments, which are made of iron ·012in. thick, it is so arranged that the adjacent plates break joint. The revolving masses of iron which complete the magnetic circuit are also laminated, and are clamped in position by bolts passing through two steel discs, Fig. 8. The action of these revolving keepers can best be understood by means of separate sketches, Figs. 9, 10, and 11. In these only one armature core is considered, as the action on all of them is similar.

In Fig. 8 the keeper bridges cross the armature and the south pole of the field magnet, so that the lines of force pass as shown by arrows. Fig 9 shows the condition of the magnetic circuits when the keeper has passed on till it is exactly opposite the armature core. Then the actions of the north and south pole tend to produce equal and opposite magnetic flux in the armature core, and hence neutralise each other, so at that instant no lines of force pass through the armature core, but they will go as indicated. In the next, Fig. 10, the keeper unites the north pole to the armature, so that the flux is again a maximum, and in the opposite direction to that in Fig. 8. The keeper has now been moved through one thirty-second of a revolution, as there are 16 poles, and the E.M.F. induced will have passed through half a complete period. So in this machine the number of complete periods per second is equal



70-Kilowatt Kingdon Inductor.

in which the E.M.F. is produced by changes in the magnetic path. These changes cause a fluctuation of lines of force in certain definite places where the armature coils are situated. The diagrammatic sketch of the armature arrangements will help to show the method used, but unfortunately the sketch is not to scale, and the relative proportions are not the same as in the machine exhibited

to the product of the number of poles into the revolutions per second, and not half this quantity, as in the alternator described above. The action of the keeper in inducing the E.M.F. in the armature coils is not the only one that takes place, and it is doubtless the need of preventing the secondary effects that has induced the pending alterations in the design.

On comparing Figs. 9 and 10, with respect to the magnetic resistance of the iron circuits, it will be seen that in Fig. 10 the resistance offered to the magnetic flux is, roughly, double that in Fig. 9, but also the ampere-turns producing the flux are doubled, as two coils are acting, so that there should be about the same number of lines coming from each pole. But in a position about midway between these two there will be no such relation, and the resistance will have increased without a corresponding increase of magneto-motive force. This will cause a variation of the flux in the magnets and time to produce an alternating current in the exciting coils. This effect, and the large masses of iron exposed to changes of induction, and hence causing a large hysteresis loss, are the objections to this class of machine, but they may be reduced considerably by careful design. The advantages are all based on the fact that neither of the electric circuits are on the rotating parts. Thus no collector is required in either circuit. Also the insulation of the conductor is not so likely to break down, due to the mechanical vibration, as there will be little vibration in the fixed core. The present machine was connected up to give 110 volts when at the Palace, although it was never actually working. The connection-board at which the armature coils were connected would facilitate the rapid change from parallel to series, but the insulation appeared to be more fitted for low-tension working. The power required to excite the magnets is 6·8 per cent. of the total output, which is the highest figure in the adjoining list. The armature reaction will help to make this figure high, as the air spaces are short. The noise made by this alternator when running at full speed is objectionable, but doubtless the makers will remedy this when bringing out their new pattern.

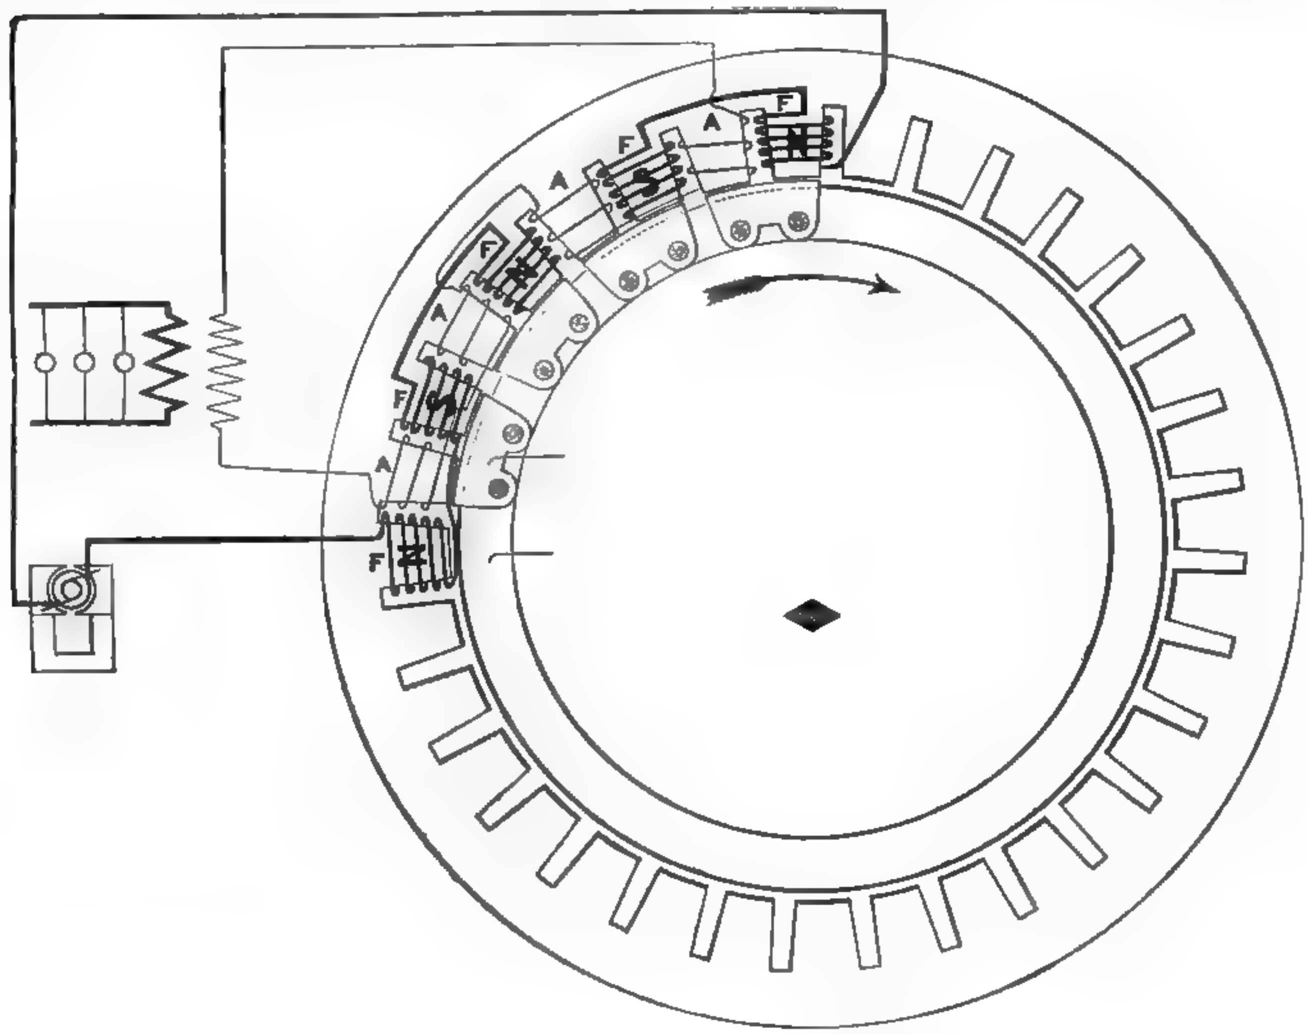


Fig. 8.

Most of the details of this machine can conveniently be taken from the adjoining list, but the following are not included: Diameter of outer ring of laminated iron 5ft. 7½in., width 1ft. 0¾in., the iron plates being ·042in. thick. The magnets are wound with 144 turns of ·200in. by ·063in. strip and connected in parallels of four in series. They are excited by a current of 80 amperes at 60 volts.

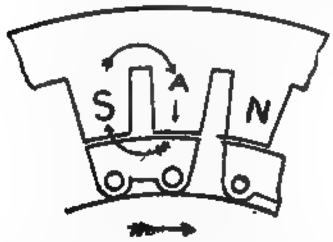

Fig. 9.

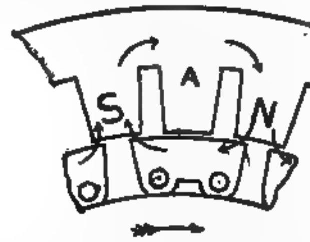

Fig. 10.

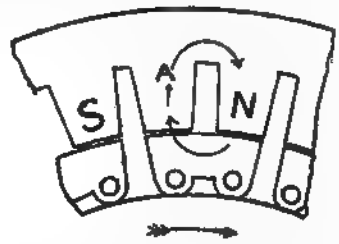

Fig. 11.

The adjoining list of alternators, of which I have already described the construction, will enable some idea to be formed of the relative advantages of the various types. The first few columns need no comment, but it is of interest to note the number of complete periods per second. The larger Kapp alternator, giving 100 periods, must be taken as an exception to the general practice.

* The cores only are of wrought iron fitting into cast-iron frames.

† Cores of wrought iron cast in the frames.

of the English makers of this design, as it was built to a foreign order. Then, out of seven makers two have adopted the use of 100 periods per second, and the other five show an average of about 70. The hysteresis loss in iron-cored armatures increases with the frequency, and this forms a special reason for keeping it low. The great advantage of increasing the frequency is that the weight of the transformer can be reduced in proportion.

The output of the alternators given is that fixed by the makers, and as they may have widely different ideas of what the output should be fixed by, it is not a definite amount. Still, on comparing the outputs per weight and square foot of floor space, it will be seen that the figures do not vary much. It must be remembered that the Brush magnets are made entirely of cast iron, which is likely to make the output per weight quite 40 per cent. lower than if wrought iron was used. In this column three machines give the high figure of about 20 kilowatts per ton—namely, the Gulcher, the Kapp, and the Siemens. In the column showing the output per square foot of floor space, the order commencing at the highest, is Kapp, Kingdon, Fricker, Siemens, Mordey, Ferranti, and Elwell-Parker.

The mean circumferential speed of the armature or moving magnets is in each case much higher than that adopted in direct-current dynamos. The limiting safe speed is, of course, a function of the mechanical strength of the design. Messrs. Johnson and Phillips work at the highest speed, 8,000ft. per minute, and their construction of core is well able to stand this. The Brush Company's magnets have a circumferential speed of 6,300, and the other makers show an average of about 5,000ft. per second. The amount of power used to excite the magnets, and given in that column, is definite in all instances except the first. The Brush Company have not given the exact exciting power for each machine, but state that it averages about 2 per cent. As regards the material used for the core, four of the seven makers use iron, and the others use respectively porcelain, laminated brass, and wood.

The efficiency of each machine would form a most interesting calculation; but to enable the exact efficiency to be determined, a few more details—such as the polar area, the air gap, etc.—would be required, and it is not fair to publish approximations only. The losses due to Foucault current would also have to be determined, as this loss is likely to be a large item. Messrs. Siemens and Co. have adopted the laminated conductor, and Messrs. Johnson and Phillips have subdivided their armature conductor with a view to reducing this loss, but as yet will publish no particulars of what percentage loss they find due to this cause. The comparative hysteresis losses in the various iron-cored armature can be roughly obtained by comparing the quantities of iron used.

In conclusion, I have to thank the various makers for their courteous answers to my enquiries for particulars of their alternators.

EXPERIMENTS ON ELECTRICAL RESISTANCE.*

BY DAWSON TURNER, M.D.

The author had the pleasure when in Paris of seeing some of Mr. E. Branly's experiments on the influence of currents of high potential upon electrical resistance. He has since repeated some of these. It is well known that metallic powders present a very great electrical resistance. This can be lowered to an extraordinary degree by the passage of a spark in their neighbourhood. The author has tried, amongst other substances, powdered aluminium, copper, annealed selenium, iron filings, small shot, mixtures of aluminium and resin fused into a solid stick, etc. The best results were obtained with the first two. A short glass tube is filled with powdered aluminium, and placed, by means of copper wires passing through corks, in circuit with one or two cells and a galvanometer. The resistance of the aluminium is very great, and the needle of the galvanometer will remain at zero. If, however, a spark from an induction coil be passed anywhere in the vicinity, the

* Paper read before the British Association at Edinburgh.

resistance will become at once very much diminished, and the galvanometer needle will be deflected. Thus, though there was at first no appreciable current, there may now be one of 250 milliamperes. The powder will, if undisturbed, remain a conductor for some little time; but if the table be shaken, or the glass tube be moved, the initial resistance at once returns, and the needle passes back to zero. After the resistance has been once lowered in this way, the powder gets into a very sensitive condition—a spark at a great distance lowers the resistance, and the slightest jar restores it. The author was not successful with ordinary iron filings, perhaps because they were not sufficiently finely divided. Mere shaking does not restore the resistance of the solid stick of aluminium and resin, but the application of a little warmth is sufficient.

The experiments would appear to suggest that the molecules of the powders become arranged in such an order as to conduct electricity when an electrical discharge occurs in their neighbourhood, and that the slightest mechanical jarring suffices to destroy this arrangement. It does not appear to matter which way the induction current is passed.

PROF. EWING'S MAGNETIC CURVE-TRACER.

At his evening lecture on "Magnetic Induction," delivered on Monday last, and again on Tuesday, before Section A of the British Association, Prof. Ewing exhibited an apparatus for automatically drawing curves to exhibit completely the relation of magnetism to magnetising force in samples of any iron or steel.

Specimens of Curves obtained with Prof. Ewing's Curve-Tracer.

The apparatus can be arranged so that a complete H B cycle can be gone through in $\frac{1}{10}$th or even $\frac{1}{50}$th of a second, the result being a continuous line of light upon a screen.

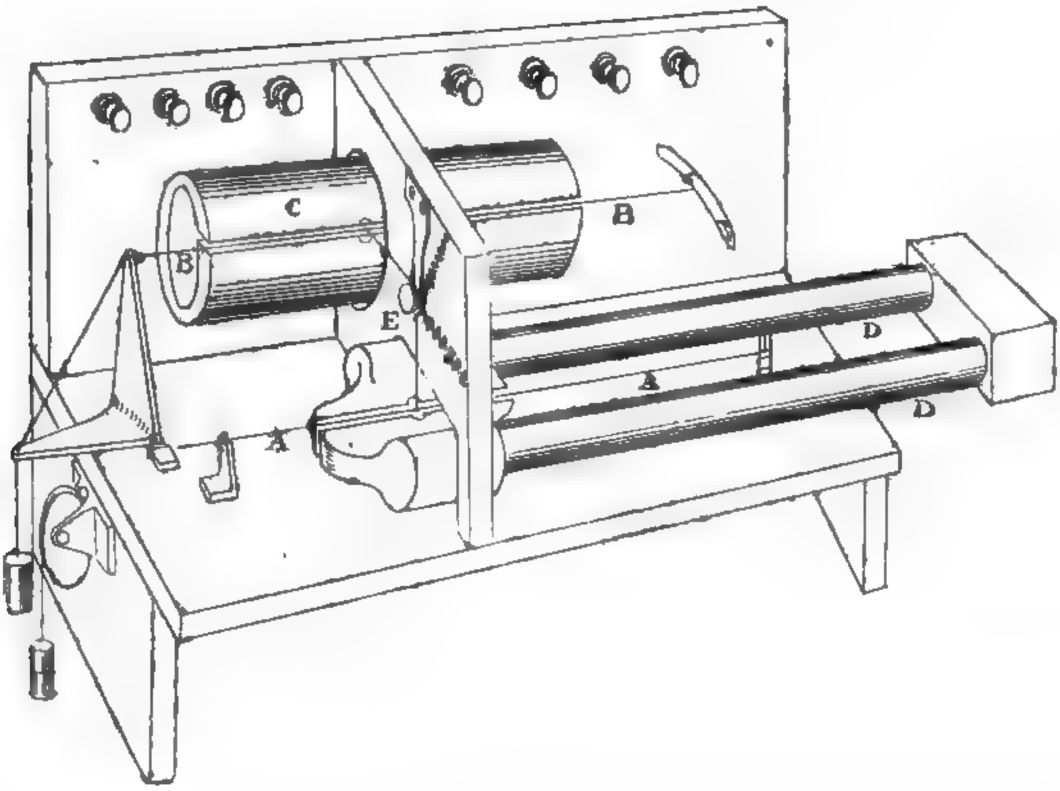

Fig. 1.

The principle of the apparatus will be seen at a glance. E (see Fig. 1) is a mirror, mounted with two degrees of freedom, capable of altitude and azimuth movement. It receives azimuth movement from the wire B B, which is stretched in a narrow gap in an electromagnet, C. It receives altitude movement from a wire, A A, which is stretched in a narrow gap between the pole-pieces of the magnetic circuit, D D, consisting of the rods to be examined. A constant current is passed through the wire A, and it therefore sags, up or down, proportionately to the field across the gap; in other words, proportionately to the magnetism of D D. The variable current which flows in the coils of D D passes also through the wire B. Hence, since the field of C is constant, B sags out or in, giving the mirror azimuth movement proportional to the strength of the magnetising current. B with its magnet, taken alone, thus forms an extraordinarily dead-beat galvanometer, and A forms an equally dead-beat magnetometer.

Small loops on the main curve can equally well be shown. In the form of the instrument suitable for slower use, it will allow of different materials being tested magnetically with the utmost readiness. A cycle can be obtained from an iron bar in a few seconds; then the bar can be taken out, and another bar put in, and its cycle drawn just above the previous one, so that a glance shows the relative hysteresis, relative permeability, and so forth—in fact, all that dynamo makers and transformer builders want to know about iron or steel. The whole process is quick enough and simple enough for workshop use.

Discussion.

Dr. Hopkinson referred to a series of experiments carried out by his son, and Lord Kelvin, Prof. Perry, and others made a few remarks, to which Prof. Ewing briefly replied.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notices of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 month
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Other Places	4s. 10d.	...	9s. 11d.	..	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

SYSTEM.

It is always understood to be the sole object in life of the country squire to put a ring fence round his landed estates. Similarly, the aim of some scientific men seems to be to connect everything in their particular branch of science under some rigid system. Thus the electrical man swears by his system of units, and anything that has not yet been brought into line must at the earliest opportunity be dragged in, no matter how doubtful it be whether another year with its records of progress will not show this particular haste to have been premature. In a progressive and undeveloped branch of science this haste is a nuisance. It is so electrically. We live in a period of constant change. The student of to-day wishes he had a name for some particular phenomenon, and to ease his conscience proceeds at once to coin one. A year hence fuller knowledge tells him the name wanted is for another phenomenon, and not for the one already named. Then to crown the edifice of Tantalus, the electrical student is a hero worshipper. The name of his particular Gamaliel must be handed down to posterity as one of the shining lights of a period which, when compared with the period over which scientific investigation has extended and will extend, is as nothing. His heroes are those immediately in front of his eyes. His allegiance to their infallibility is so great that although the whole theories of the science are changing, he cannot see that they may be wrong. Gilbert was a giant in his day, but how many of the present-time electricians know his work, except as contained in a big book under a glass case at some exhibition. No doubt the hero worshipper of Gilbert's time would have desired to have handed his name down to posterity in some such way as it is proposed to hand present-century names down to posterity. We imagine the better course to pursue it to follow the lead of the philologists, so that the word itself shall contain some indication of its meaning. The Greek, and perhaps the German, would have made a compound word to indicate pressure, current, energy, power. We can give the names volt and ampere, but kick against volt-ampere, a compound word, and favour watt—a term conveying in itself no meaning. Enough, however, of this word-coining, which might be tolerated, perhaps, especially when euphonious; but what is more important, is to insist upon a time of quietude. If changes in nomenclature are to be introduced at Chicago next year, let those changes be final for a quarter of a century. Elsewhere we give Prof. Lodge's suggestions, not as given at the B.A. meeting, but as intended to be given. As a matter of fact, the whole meeting was an example of presidential courtesy in saying time is short, therefore cut your paper or remarks short. Hence Dr. Lodge was hardly given a show. It was clear, however, that a mass of opinion was distinctly against change. If things are not perfect, let them slide. Make shift for a few years till we can see better what exactly is wanted. There may be some anxiety to have a perfect system, but when such men as Dr. Lodge admit that

the terms "watt" and "joule" are hardly necessary, it will be just as well, as Dr. Hopkinson suggested, to wait for further consolidation of the whole subject before introducing new or changing old terms.

LANE FOX AGAIN.

In our issue of April 8th we commented upon one of the points raised in the evidence given in this case. Notification was given us of an appeal, hence any further comments were impossible. The appeal has been tried, and judgment delivered, the original judgment of Mr. Justice Smith being upheld. There is still one more step which infatuated litigants may take—appeal to the House of Lords. Enough money has already been wasted—sufficient indeed to have put up a good-sized central station—and in our opinion needlessly wasted. Our contention all along has been that a clever man has attempted to ram down the throats of the industry, by the light of the knowledge of 1892, a patent that was of the nature of a fishing patent taken out in 1878. Bit by bit has been disclaimed, with the intention of leaving just those sentences which might be construed by a court of law as indicating knowledge and invention. We are glad that the attempt has failed, but it was almost a success. It would indeed have been a disgrace to our legal institutions if a patent which has largely been disclaimed, and the "invention" of which the patentee, when in a position to do so, never carried to success—we say it would have been a disgrace to have had such a patent upheld. In our opinion the best proof of the worthlessness of the "invention" is proved by the patentee's own action. When all-powerful with the old Father Brush Corporation, his efforts were not directed to the perfection of this now-claimed master patent, but to something else. We are speaking strongly because we feel strongly. An attempt has been made to coerce and hamper the whole industry because of the accidental rather than the conscious, intentional language used in the patent specification. As we pointed out at the time when Mr. Justice Smith's judgment was given, so exceedingly able were Mr. Lane Fox's advisers that it was made to appear that certain facts were well known in 1878, ..., for example, the use of the term "earth" for ...tallic returns. It will be seen that the appeal ...dges accept this as correct; also they accept as a ...covery of Mr. Lane Fox that a constant pressure ... or about 100 volts is something essential. Our ...ders, of course, know that there is nothing about ...0 volts to render such a pressure essential. But ...e irrational conclusions are all swept aside in ... finding the apparatus as described "won't ...rk." A simple way in order to save money, ...ld have been for the judge or judges to be able ... order an independent authority to run the Law ...rts installation on the method described by ... Lane Fox. This would have sufficed to prove ... real and true value of the apparatus. For...tely, or unfortunately, our opinions are not in ...rd with those expressed by some of our con...poraries, hence there is always the incentive ...use of such differences of opinion for a litigant to say, "The higher court may also have a different opinion to the lower court." Pity it is so, and that more money may possibly be wasted. We trust in this case Mr. Lane Fox has had enough of law, and will be satisfied with the verdict.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE DAY LOAD.

SIR,—You are continually pointing out in your periodical the necessity for a day load to electric lighting plants.

In a large district there must be several people who would utilise electricity for numerous purposes if they could get it without any original extravagant outlay, especially where their requirements are very irregular.

I suggest that the electric light companies might start a stock of accumulators and suitable transporting carts or waggons. These accumulators could be supplied in any quantity as desired at either regular or irregular intervals, and would form a probable stable support to the lighting industry.

The above may not be practical, but if you deem it to be so it might prove useful to some if inserted in your issue.—Yours, etc., R. S. WALKER.

St. Mary's Barracks, Chatham, Aug. 5, 1892.

[We heartily agree with the ideas expressed by our correspondent.—ED. *E. E.*]

A CONTRIBUTION TO THE THEORY OF THE PERFECT INFLUENCE MACHINE.*

BY J. GRAY, B.SC.

The history of the development of the heat engine appears to have repeated itself very closely in that of the electrical influence machine. The early experimental gropings of Savary and Newcomen, in the case of the steam engine, run parallel with those of Darwin, Nicholson, and others with the influence machine. These efforts resulted in machines certain, it is true, in their action, but, from ignorance of principles, very inefficient in their design. A closer study of the working of the steam engine and the application of higher principles by the genius of James Watt produced a machine of much higher efficiency, and left little for his successors to do except the perfecting of details, till another great advance was made in the theory of the heat engine. The labours of Holtz, extending over a period of 20 years, during which he worked out and perfected in infinite detail almost all the leading types now in use, has earned for him a good claim to be considered the Watt of the electrical influence machine.

The third stage in the development of the heat engine coincides with the rise in the science of thermo-dynamics; and the investigations of Carnot, Thomson, Rankine, and others showed that the heat cycle through which a mass of working fluid must pass in order to give a maximum efficiency must be made up of adiabatic and isothermal lines. An analagous principle to the above has been applied by Clerk Maxwell to the influence machine, for he has shown that the cycle of the perfect influence machine must be made up of what may be called equiquantic and equipotential lines, corresponding respectively to the adiabatic and isothermal lines of the heat-engine cycle.

The object of this paper is to describe some graphic methods which, I think, help to elucidate the action of Maxwell's machine, and to show by what amount the efficiency of the influence machine may be increased by the application of Maxwell's principles.

Maxwell points out that over and above the loss from leakage, there is a loss of energy in the influence machine through the sparking which takes place just before a carrier makes contact with the charging or discharging points in

* Paper read before the British Association at Edinburgh.

its course. The energy lost is $\frac{1}{2}$ Q V where Q is the quantity of electricity transferred and V the difference of potential producing the spark. The object of his invention is to do away with sparking. He effects this by causing the carrier of electricity to make contact with charging and discharging springs when its potential is the same as that of the spring in question, and to remain in contact during the whole time of charge or discharge.

Fig. 1 is a diagram which will serve to show the action of Maxwell's machine. Conductors are drawn in thick dark lines, and insulators left white, a convention in accordance with the electromagnetic theory of light.

The machine consists of six fixed hollow conductors, A, B, C, A^1, B^1, C^1, which may be looked upon as six sections of a hollow anchor ring, separated by insulating air spaces. A conducting carrier, P, is caused to revolve through the centre of the hollow conductors in the direction shown by the arrow. Three of the conductors, A, B, C, are connected to a Leyden jar of large capacity, charged to a positive potential, V. The other three conductors, A^1, B^1, C^1, are connected to another similar Leyden jar charged to a negative potential, V. The conductors taken in order round the ring are thus alternately positive and negative. The dotted line on the diagram is drawn to represent approximately the potential at each point of the circular path through the centre of the conductors along which the carrier, P, travels.

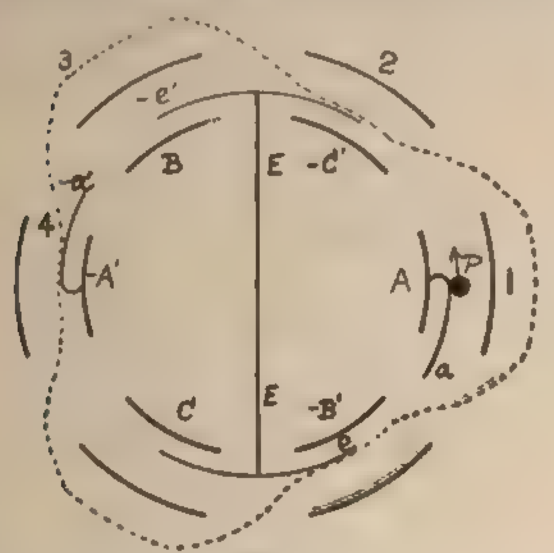

Fig. 1.

The potential at each point is indicated on the diagram by the distance (positive or negative) of the dotted line from the outer circle of the diagram. To the conductors A and A^1 are connected contact springs, a and a^1; and lying partly inside the conductors B and C^1 is a spring, e^1, connected to earth or to a similar spring, e, lying partly within the conductors B^1 and C.

The changes in the energy of the carrier, P, during one complete revolution and the work done upon it are best shown by a Q V diagram—*i.e.*, an energy or work diagram in which the components are the quantity and potential of the carrier.

Let Q O Q, V O V be the axes of co-ordinates: distances along O Q representing quantities of electricity on the carrier, and distances along O V representing potentials of the carrier.

We shall start with the carrier, P, as represented in Fig. 1, just about to break contact with the spring a, which is connected with the conductor A. The potential of the carrier will be equal to that of A, which we will represent by an ordinate, P N. Its quantity, due to its not being completely surrounded by the conductor A, may be represented by O P. As O P = V tan P N O, tan P N O equals (with proper units) the capacity of P with reference to the earth. Let tan P N O = α.

The point, N, on Fig. 2 corresponds, therefore, to the position of P on Fig. 1. In passing from its initial position till it comes in contact with the earth-spring, e^1, inside the conductor C^1, P retains its charge unchanged in quantity. We will suppose that S P represents the potential carrier, P, when about to make contact with the spring, if the conductor C^1 were removed. In o reduce the potential of P to zero, when it makes co the coefficient of induction, say, C^1 of the conduc upon P, must be such as to produce an equal and op quantity to O P on the carrier, P. Therefore

$$C^1 = \frac{\overline{OP}}{V} = \frac{\alpha V}{V} = \alpha$$

is the equation for determining the coefficient of ind which the conductor C^1 must exert upon the carrie the moment of contact.

The state of the carrier is now represented by th P on Fig. 2. The passage of the carrier along the e^1 is represented on Fig. 2 by the line, P T^1, during there is a gradual loss of quantity at zero potential carrier finally leaves the spring with a negative represented by O T^1. From contact with the sprin contact with the spring a^1 the quantity remains co but the potential falls—*i.e.*, we pass from T^1 to Fig. 2. Along the spring a^1 the quantity increases po or decreases negatively at constant potential, – V passes from M^1 to N^1 on Fig. 2. This completes o of a revolution, and the other half is exactly similar opposite—namely, along N^1 P^1 T M N back to the st point.

The work done on the carrier in one revolution is to twice the area of the rectangle, N T. A quantity of positive electricity is imparted to the conductor A equal quantity of negative to A^1; the potentials of quantities being V and – V respectively.

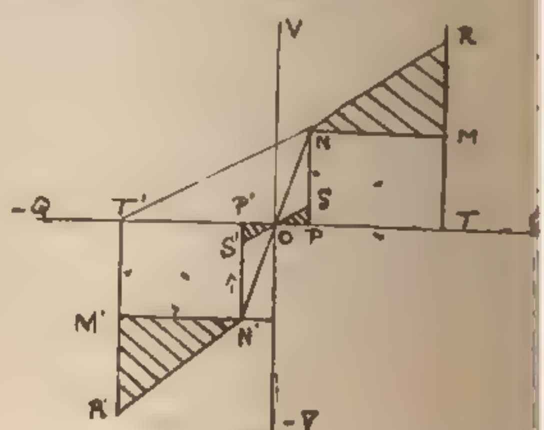

Fig. 2.

The efficiency of the machine in such a cycle is that is to say, there is no loss—friction, leakage, etc. left out of account.

The quantity produced per revolution is less th maximum possible by the amount left on P when it the discharging conductors, A or A^1.

The conductors C and C^1 are called by M regenerators, because their function is similar to that regenerator in a heat engine.

Let us now, in the first place, consider how mu efficiency of this influence machine is reduced b removal of the regenerators. The effect of remov will be to allow the carrier, P, to spark to the sp before making contact, and the energy dissipated spark is equal to the area of the triangle S P O. Th a similar loss in the other half of the revolution efficiency, E, will now be

$$E = \frac{QV}{QV + \frac{1}{2}\alpha V . \overline{SP}};$$

$$= \frac{1}{1 + \frac{1}{2}\frac{\alpha . SP}{Q}}.$$

This efficiency approaches unity as α or $\overline{SP}$ app zero, and in an actual machine α can be made very

Let us now, in the second place, consider the l efficiency due to replacing the long contact springs, a^1, by contact points inside the conductors A and A

approaching and entering the conductor A, the potential of P will not stop at M, but will rise to R before discharge.

If the capacity, a, is very small, and the conductors B^1 and A have equal coefficients of induction on the carrier, M R will be very nearly equal to M T. The energy dissipated in the spark is equal to the area of the triangle R M N. The efficiency would now be—

$$E = \frac{1}{1\frac{1}{2}} = \frac{2}{3}.$$

The absence of long contacts in the receivers thus leads to a much greater loss of efficiency than the absence of the regenerators.

CONTACTS		REGENERATOR	EFFICIENCY
CHARGING	DISCHARGING		
LONG	LONG	PRESENT	1
		ABSENT	$\frac{1}{1+\frac{aV}{Q}} = 1$
	POINT	PRESENT	$\frac{2}{3}$
POINT	LONG	ABSENT	$\frac{1}{1\frac{1}{2}+\frac{aV}{Q}} > \frac{2}{3}$
	POINT		$\frac{1}{2+\frac{aV}{Q}} > \frac{1}{2}$

If points are substituted for long contacts in the charging conductors, B and B^1, a moment's inspection will show that the loss by each spark is the area of the triangle P N T^1.

Then
$$E = \frac{QV}{\frac{1}{2}(Q+2aV)V};$$
$$= \frac{1}{1\frac{1}{2} + \frac{aV}{Q}} < \tfrac{2}{3}.$$

Finally, when all the contacts are points, as in the ordinary influence machine, the efficiency

$$E = \frac{1}{2 + \frac{aV}{Q}} < \tfrac{1}{2}.$$

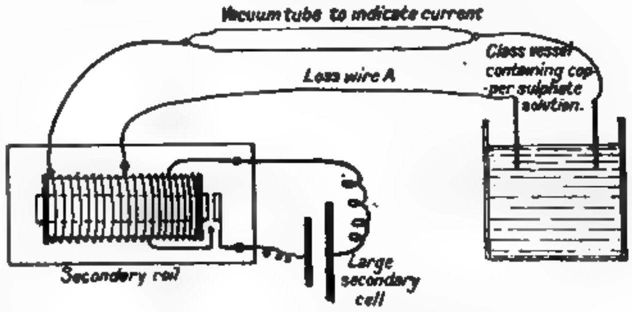
I have made a machine with long contacts, but without regenerators, which is self-exciting, and gives considerable quantity; but owing to difficulties of insulation, which I hope soon to overcome, I have not been able to get long sparks. These graphic methods may be applied to any influence machine for investigating their efficiency.

SOME EXPERIMENTS WITH A RUHMKORFF COIL.*

BY MAGNUS MACLEAN, M.A., F.R.S.E., AND ALEX. GALT, B.SC., F.R.S.E.

The quantity of electricity induced in a secondary circuit by a *make* in a primary circuit is equal to the quantity of electricity induced in the same secondary by a *break* in the primary. This fact was first experimentally proved by Faraday, and subsequent experiments and theory corroborate the statement. If, however, there is a non-metallic gap in the circuit, whether of air at ordinary pressure, or at much reduced pressure, as in vacuum tubes, the *break* impulse causes a flow in one direction, and the *make* causes either no flow or a much less flow in the opposite direction; because the short intense impulse of the former breaks down the resistance, while the comparatively long and less intense impulse of the make either does not break down the resistance at all, or only does so to a much less degree, so that the effective resistance is much greater in one direction than in the other. To obtain the average difference of quantity of electricity set in motion in one direction above that in the other, a copper electrolytic cell was put in circuit with a vacuum tube and the secondary coil of a small Ruhmkorff coil. The solution in the cell is sulphate of copper of density 1·17 with one-half per cent. of commercial sulphuric acid added. The electrodes were No. 36 B.W.G. copper wire (0·012 centimetre diameter), and they were immersed in the solution as little as possible, so as to get the best current density for the deposit. The mean of seven experiments lasting from two to four hours gives the average electrolytic current, calculated from the gain of the cathode electrode, as one-sixth of a milliampere. The gain of the cathode electrode was, in six of the seven experiments, greater than the loss of the anode electrode. An electrolytic cell was also put into the primary, and the mean ratio, in three experiments, between the gain of the cathode in the primary and the gain of the cathode in the secondary was 6,000. The mean current in the secondary was still about one-sixth of a milliampere.

One or two experiments were also tried without a vacuum tube in the secondary circuit, simply the electrolytic cell. Both electrodes showed loss. Again, a long thermometer



tube full of sulphate of copper solution was substituted for the vacuum tube. The resistance of this tube would be comparable to that of the vacuum tube. (A Thomson multicellular was put at the terminals of the vacuum tube, which showed 165 volts. This would give the effective resistance of the vacuum tube to disruptive discharges as $165 \div \frac{1}{6000}$ = one megohm.)

The few experiments done with this thermometer tube in the circuit are inconclusive, as sometimes both electrodes showed loss, and in an experiment lasting hours neither electrode showed either gain or loss. These last experiments are to be continued with slight modifications. It is also intended to attach a tube to an exhaust pump, and try these electrolytic experiments at different pressures, from atmospheric pressure down to very low pressures or very high vacuums.

* Paper read before the British Association at Edinburgh.

ON THE DIELECTRIC OF CONDENSERS.* †

BY W. H. PREECE, F.R.S.

Artificial cables are very useful adjuncts to the laboratory of the telegraph engineer. They not only enable him to experiment at his leisure, but they form very useful means to test and compare high-speed and delicate telegraph apparatus, and especially telephones. I have one, made some years ago, which has been in incessant use, composed of 54 inductionless coils of insulated copper wire, each giving 33 ohms resistance, and having a condenser of one microfarad capacity at the juncture of each pair of coils. This represented a circuit of a total capacity, K, of 54 microfarads, and of a total resistance, R, of 1,782 ohms—the K R being 96,228; this was equivalent to an ordinary submarine cable of 162 nauts length. It was not sufficient for our growing wants, and another similar set was recently made; but it did not give the same results. The resistances were exactly the same, but the individual capacities differed. This difference of about 5 per cent. was of itself of no practical consequence for the particular purpose for which the cable was constructed; but on carefully comparing the two "cables" with telephones, it was found that with the same nominal K R the one gave 30 per cent. better results than the other. This was a surprising and unexpected result. I thought it might be due to inductance, but none, neither *self* or *mutual*, could be detected.

The insulation, taken after one minute's electrification, of each was:

Old cable, 172·8 megohms per naut.
New „ 82·8 „ „ „

So that the difference was in favour of the old one. But

* Paper read before the British Association at Edinburgh.

† Lord Kelvin proposes to call this useful instrument a "Leyden," because the term "condenser" is applied to other more appropriate mechanical and physical apparatus.

the electrification of the new one was much less than that of the old one. The difference in the reading between the first and second minute, on the former, was one-twentieth of that of the latter.

Each cable was then rapidly charged and discharged 1,200 times, at varying rates, with an E.M.F. of 40 volts, and the cumulative remaining charge in each case read by deflection on a Thomson galvanometer. This was done by passing a 10ft. length of perforated slip through a Wheatstone's automatic transmitter. The following are the results:

Number of discharges per second.	Discharge.		Percentage difference.
	New.	Old.	
20	46	28	39
40	86	55	36
80	151	100	33
120	200	136	32
160	237	168	29

This clearly shows that the effect is due to absorption. Electrification, polarisation, and absorption are phases of electrolytic work done by the current upon the dielectric. The material itself, or the impurities contained in it, are slightly decomposed by the leakage current, a counter E.M.F. is set up which increases the apparent resistance (electrification), it gives a current of discharge reverse to that of charge (polarisation), it absorbs a quantity of electricity, the undissipated part of which is recovered as a discharge current. The condenser acts, in fact, like a secondary cell.

We are now using better paper than formerly, that made from the best linen rags, thinner tinfoil, and better wax, the best refined unadulterated white paraffin, having a melting point of from 125deg. F. to 128deg. F. Resin was formerly mixed with the wax, and when hot and liquid it was painted on the paper with a brush. The paper is now thoroughly dried and well saturated with wax by soaking under pressure, so as to get rid of all the moisture. Hence there is less electrification and less absorption, hence the difference. In the old type of condenser we observed a variation of capacity due to temperature, but in the new type this has disappeared. This effect of absorption on the effective capacity of the condensers and of insulated conductors is new to me, and as it may be new to many others I have thought it to be of sufficient interest to bring it before Section A.

It is a new term to be added to the equation of energy of compound circuits, and it has evidently a material influence upon the retardation of signals in long submarine cables. It has an equally important influence on the efficiency of telephone circuits, and it accounts partially for the great difference in my KR law between the observed effects of aerial and those of subterranean or submarine conductors. The former are always much superior to the latter. This would be due to the absence of polarisation in air, as well as to other electromagnetic and electrostatic causes. No work would be done on the molecules of air, no energy would, therefore, be absorbed, and no retardation of currents from this cause would ensue. An air dielectric is clearly the "Holy Grail" of the electrician.

ELECTRIC LOCOMOTIVES: SOME RESULTS IN ACTUAL WORKING.*

BY ALEXANDER SIEMENS.

The object of the present communication is to place on record the performances of two electric locomotives, the most powerful of their kind, which were supplied at the end of last year by Messrs. Siemens Bros. and Co. to the City and South London Electric Railway.

In the year 1888 the company, then called the City of London and Southwark Subway, issued a specification asking, among other things, for electric locomotives capable of developing a maximum of 100 brake horse power. Owing to financial considerations the contract was not placed with Messrs. Siemens Bros. and Co., although a perfect agreement had been arrived at on the technical points of the question.

The City and South London Company, however, invited Messrs. Siemens Bros. and Co. again in the beginning of last year to tender for locomotives in accordance with a specification practically identical with that agreed upon in 1888; and as a result two electric locomotives have been built and are now working.

Each locomotive carries two motors, and the use of all gearing is obviated by winding the armatures of the motors on the axles of the wheels of the locomotive. This method of construction was illustrated by a model shown at work at a meeting of the Society of Arts on May 18, 1881, and had been first suggested by Sir William Siemens, who, at the time of his lamented death, was actively preparing a proposition to work the Metropolitan Railway by electric locomotives.

The motors for the two locomotives were tested before they were fitted into their places by means of a Prony brake, and some of the results of this first set of tests are given in Table A.

TABLE A.

Speed in miles per hour	Electrical h.p. put into mot'r armature.	Electrical h.p. put into m'tor magnets.	Total electrical h.p. per motor.	Total el'ctrical h.p. per loco.	Brake h.p. measur'd	Effic'y per cent.

A. Average running speed, miles per hour exclusive of stops.

Since the two locomotives have been set to work on the railway they have had to keep the same time as the other so that their full power cannot be utilised, but it has been found that their efficiency is satisfactory in every respect.

Observations of the current and E.M.F. have recently been made simultaneously, by taking sets of readings of the ammeters and voltmeters, both at the generating station and on the locomotive. From these observations the curves accompanying these notes have been plotted. At the time these observations were made the locomotives had run about 8,000 statute miles, and on all four motors the brushes were wearing at the rate of about ⅛in. per 1,000 miles run; this small wear being a consequence of the motors running sparkless and practically without heating.

On examining the curves it will be noticed that there is no similarity whatever between those representing the volts at the generating station and on the locomotives respectively; this is, however, easily explained by the consideration that the volts at the generating station are influenced by all the trains in motion at the same time, while the volts on the locomotive are principally influenced by the demand of the locomotive itself.

* Paper read before the British Association at Edinburgh.

When the train is started, the current is regulated by the driver, so as not to exceed a certain amount, by means of switches inserting resistances into the main circuit, but these resistances are cut out within half a minute of starting, so that the waste of energy in the resistances is kept as low as possible.

Each locomotive, fully equipped, weighs 13½ tons, and the weight of the train of carriages it has to draw is about 21 tons. To this the weight of the passengers has to be added.

A summary of the results is given in Table B, which shows that the average power developed by each locomotive requires a current of not more than about 50 amperes, although in starting as much as 140 amperes are required.

This fact illustrates at the same time the peculiar difficulties which have to be grappled with in the construction of such locomotives, which have to work under conditions almost diametrically opposite to those of generating dynamos in electric supply central stations.

Discussion.

Prof. Unwin said he thought that at the present time there was hardly anything more important than the proper construction of electric locomotives.

Mr. Greathead, having described the nature of the line, said the steepest gradient was 1 in 30, and that on a sharp curve it would be seen that it is an exceptionally heavy one for all kinds of traction, except perhaps cable, for which the line was originally constructed. There were now four engines at the generating station, but two were sufficient, and when the traffic was light, one would be sufficient; there was therefore a large margin to allow for extension of traffic when the line was carried, as it was intended to do, to Clapham. He mentioned that the average load per train throughout the year was 51 passengers. The Siemens locomotives had worked very satisfactorily and without stoppage from any cause. There were 14 locomotives of the Mather and Platt make, and it was decided, after much anxious consideration, to adopt gearless locomotives. He mentioned that the Siemens armatures, after much running, had been found quite cold, and no repairs whatever had been necessary.

Dr. Silvanus Thompson said the motors as used were probably but an intermediate type between the small ones of the past and the larger ones of the future. It would be found necessary to build electric locomotives with big, heavy, and strong field magnets, and constructors must not be afraid of dead weight.

Mr. Traill said he was still using Siemens motors on the Portrush line, which were made in 1883, and the generators now in use were of eight tons.

Prof. G. Forbes wished to point out one or two causes of trouble in the past. Firstly, in the failures of the smaller armatures; these had been due almost entirely to heating, and consequent breaking down of the insulation. In the case of the City and South London Company's line the change of design was to a great extent responsible for the heating effect. The Professor here showed how the position of the field magnets, as originally intended, had been changed, and how parts of the field magnets had been cut away to allow for this change. He, as having originally suggested carbon for brushes, protested against the wrong use of carbon brushes, and advocated the use, not of one carbon but of several, each with an independent spring. Referring to the tables he called attention to the fact that all the trouble came in at the starting point, and not at the high speeds, and asked for further information from the author.

Mr. Alexander Siemens thanked the various speakers for their congratulations. He said in the generating station there were two machines, and there were also only two circuits. He was glad to know that Dr. Thompson considered that his company had made progress in electric locomotion. Respecting what Prof. Forbes had said, he thought a distinction must be made between those wound on the Gramme and those on the drum principle. As to carbon brushes he considered any kind of brush, whether of carbon, copper, or otherwise, if well made and used, there was no practical difference.

The **President** (Prof. Unwin) thought it was very generous of Mr. Siemens to give such good data for working as he had. He thought that the building of his armatures and big field magnets would eventually lead to the mechanical engineer being called upon to consider the question of the disaggregation of the axles of big motors. He then proposed the usual vote of thanks.

THE BRITISH ASSOCIATION COMMITTEE ON ELECTRICAL STANDARDS.

BY PROF. OLIVER J. LODGE, F.R.S.

In view of the hoped-for presence of Prof. von Helmholtz d other distinguished foreigners at this year's meeting of e British Association in Edinburgh, it will probably be cognised as suitable to take up and continue the discus- n on new electromagnetic units for practical purposes, ich was begun last year at Cardiff.

I therefore beg to contribute the following notes, and to conclude by moving some resolutions.

One great fact brought into prominence by the practical development of electricity is the analogy or reciprocity between the electric and the magnetic circuit, and this is the fact which it behoves us to emphasise in the naming of fresh units. The magnetic circuit has as yet no authorised names applied to it. The electric circuit is well provided, but perhaps one or two improvements can be made.

1. The Electric Circuit.

The first point on which I consider that practical men would do well to insist is that names shall be given to the complete things dealt with, rather than to mere coefficients. Thus of all units with which they are concerned there can be no doubt but that volt and ampere are the most prominent. These are the active things with which electrical engineers have to deal, and these are the things for which meters exist on every wall in an electric lighting station. The ohm, or unit coefficient of resistance, is comparatively academic in character; it is a constant of a coil of wire or of an underground lead; it is nothing vivid and active. The engineering use of the term ohm is mainly in connection with insulation and other high resistances; for large conductors the equivalent "volt per ampere" is perhaps more often used. It is the drop of potential which a given conductor entails for a given current that is of real interest to an engineer, and it is this of which in large leads he consciously thinks.

A six-ohm conductor means one that drops six volts for every ampere that is sent along it. If you send three amperes along such a line, the potential at the far end is 18 volts below that at the near end. The clear realisation of this fact would be almost aided by the complete title, six volts per ampere, instead of the abbreviation, six ohms. Nevertheless, the name ohm is in common use and hence may be assumed useful.

A still more useful name, however, for good conductors would really be the reciprocal of an ohm—the ampere per volt. Suppose this called a mo, as Sir W. Thomson once suggested, then a cable of 20 mos would be one that conveyed 20 amperes with a drop of one volt. A thousand-mo cable would convey 500 amperes with a drop of half a volt, and so on. It is more directly practical to think of the amperes conveyed per drop of voltage, than of the drop of voltage per ampere. I believe that some authorised name for unit conductance would be welcomed.

Units of Inconvenient Size.

The authorised name "coulomb" for unit quantity is barely used by engineers, who are content with ampere-hour, thus proving that what is needed in practical units is not so much a consistent decimal system, as a set of units each of practicable magnitude.

Farad.

The effort after consistency has resulted in the useless "farad"; and this should be a lesson not to try and fix units of unreasonable size. The C.G.S. units already exist as a consistent system; the only objection to them is that they are of unpractical size. The whole object of devising a practical system of units was to have things of everyday size to deal with. The volt, the ampere, and the ohm satisfy this condition. The coulomb, the farad, and the watt do not. Already they have practically given place to the ampere-hour, the microfarad, and the kilowatt.

Considerable more progress would have been made in knowledge of ordinary capacities if the microfarad had been called the farad, so that easy sub-multiples of it would have been available to express the capacity of Leyden jars, and such like things. The capacity of an ordinary jar would then have been a few millifarads, and a microfarad would have been the capacity of a short bit of connecting wire. I ask whether this change would introduce serious confusion even now. I think not. Nobody cares the least about "coulombs per volt," and so there is no sense or use in the present farad. Telegraphists would surely soon consent to drop the useless prefix micro, and the factor of a million is too great to render doubt possible as to what was intended, even in the transition stage. It ought to be regarded as essential to have the practical unit somewhere

not hopelessly away from the middle of the range of probable multiples and sub-multiples.

Coulomb.

A coulomb, again, is almost useless as a synonym for the ampere-second; it is so easy to speak of ampere-minutes or ampere-hours. If the name coulomb could be set free from its present superfluous meaning, it could usefully be applied to the electrostatic unit of quantity, which wants a name. Teachers would find it convenient at once, and in the apparently imminent line of development engineers might find it useful before long. It is the charge on a two-centimetre sphere at a potential of 300 volts (or on a 1ft. sphere at 20 volts). The capacity of the two-centimetre sphere would be $\frac{2}{10}$ of a (new) microfarad.

Watt.

Lastly, with regard to the watt. The name volt-ampere is almost as good as the name watt, especially since the watt is also one joule per second.

Both names—watt and joule—are not really wanted by electricians, to whom their coexistence is rather confusing. I believe it would be more convenient to use the term watt in the sense it gets so frequently used now—viz., energy, say, a volt-ampere hour; in which case a kilowatt would be synonymous with the present Board of Trade unit.

The rate of working, or power, could then be expressed in a rational and unforced way as so many watts per hour or so many volt-amperes. It is much more natural to give a name to a definite thing like a quantity of energy, than it is to give it to a mere rate of working. The latter is instinctively felt to need a reference to time; just as a velocity unit has not been practically found to need a name, being quite simply expressible in feet per second or miles per hour; and even when a name has been given, like "knot," instinct constrains people to practically get rid of it again by speaking of knots per hour, just as we find "kilowatts per hour" already often used in electrical workshops. I suggest, therefore, that the present watt is too small, that it is sufficiently expressed by a joule per second, and that it would be more useful if magnified 3,600 times, and turned into a unit of energy.

That we should thus have several energy units—the erg, the joule, and the watt—all of quite different sizes, is no objection, but an advantage, seeing the extreme importance of energy. Such things as length, mass, time, and energy demand a fair range of units. It would be tedious to express centuries in seconds.

2. Magnetic Circuit.

In speaking of the magnetic circuit I wish to refer back to my opening remarks concerning the electric circuit, and the class of things for which names should be found. In the magnetic circuit the only thing at present seriously attempted to be named is, in accordance with the historic parallel of the ohm, a coefficient or characteristic of a coil of wire—its coefficient of self-induction; the unit of which has been called variously a sechom, a quadrant, and a henry.

Total Induction.

But the real active thing with which engineers are concerned is total magnetic induction, total number of lines of force across an air gap, as between the pole-pieces or through the armature of a dynamo, or in the circuit of a transformer. It may be called the electromagnetic momentum per turn of wire, or the surface integral of B. This total induction is in some respects analogous to electric current, and has occasionally been called magnetic current (a bad name), or "magnetic flux." It is, however, more strictly analogous to the coulomb, and its time rate of variation is the more proper representative of electric current.

Its common practical name at present is "total lines," or "total induction," or "number of lines."

Now "one line" is awkward as a unit, besides being (if a C.G.S. line) inconveniently small. The earth, for instance, sends 4,400 such lines through every horizontal square metre about England. Through a square inch it only sends a fraction of a line. A practically sized unit of induction badly wants a name, and "henry" would have done for it very well, and have been both more suitable and more useful for the actual quantity than for a coefficient. But "henry" has already been half appropriated to the secohm, so, for illustrative purposes at any rate, I propose to use the name "weber" for the unit magnetic flux.

Concerning the most convenient size for the weber there is much to be said for making it 10^8 C.G.S. lines, though that is bigger than ordinarily occurs in practice, because then a wire which cuts one weber per second will have a volt difference of potential between its ends. Or a coil of 20 turns through which the magnetic induction changes at the rate of one weber per second will have an E.M.F. of 20 volts induced in it. The average E.M.F. in such a coil, spinning 30 turns a second, and enclosing a maximum total induction of one weber, is 600 volts.

This is the dynamo use of the unit; the following is the motor use.

A wire carrying an ampere and cutting a weber per second, does work at unit rate—viz., one joule per second.

Probably the simplicity of all this compensates for the rather unwieldy size of the unit. A strongly magnetised piece of iron may have 20,000 lines to the square centimetre; so a weber could occur across a narrow air gap half a square metre in area.

The earth gives an induction of about one weber through every 23,000 square metres of England, or 100 webers per square mile. The earth induction through a horizontal square metre is 44 micro-webers, so with micro and milli-webers the range would be fairly covered, though a smaller weber would have been better if it had been equally convenient as regards the volt.

The pull between two parallel centimetre square surfaces joined by a weber is $\frac{10^{16}}{8\pi}$ dynes, or 400,000 tons. A milli-weber gives less than half a ton pull; and a micro-weber less than half a gramme.

Because of the property that the voltage excited in a circuit is equal to the webers cut by it per second, a weber might be called a sec-volt. It is equal to a secohm-ampere-turn; that is to say, if a single turn of wire can have a self-induction coefficient of one secohm, it will excite a weber of induction for every ampere passing through it.

[Such a circuit in the form of an anchor ring would be enormous, something like a mile across; but it could be made in the form of a solid cylinder of best iron (μ = 2[illegible]), with an axial perforation for the wire, and 80 metres long.]

If a secohm coil has n turns, then an ampere passing through it excites only $\frac{1}{n}$th of a weber; for, since every turn encloses the induction, the latter is effective n times over, and so the induction coefficient is n times the induction per ampere, or n^2 times the induction per ampere-turn.

No name is needed for intensity (or density) of induction (B), for that can always be expressed in webers per unit area.

[For instance, strongly magnetised iron, with, say, 10,[illegible] lines to the square centimetre, has one-tenth of a weber per square foot, or 0.7 milli-webers per square inch.]

And there is a practical gain in thus leaving the specification of area open, for it enables British units of length to be employed in measuring air gaps, yokes, cores, and pole pieces.

So long as dynamo dimensions are commonly expressed in inches, there is no serious objection to specifying induction in fractions of a weber per square inch or per square foot.

Magnetomotive Force.

Now, consider the magnetic analogue of the volt, the unit of magnetic potential or magnetomotive force. By this is understood the line integral of the magnetising force H, the quantity, $4 \pi n C$, the step of potential once through and all round the circuit of a coil. It is a quantity most important in practice, and requires a name.

Mr. Heaviside has suggested the name "gaussage" as analogous to voltage, and if this were adopted the unit of magnetomotive force would be the gauss. The intensity of magnetising force would be the gauss gradient, or drop of gaussage per centimetre. No special name is needed for the unit of this quantity, H.

The common practical unit of gaussage at present is the ampere-turn, and this has several advantages. It may, however, be found better to make some convenient number of

engineers may be satisfied with and be willing to adopt. I need hardly say that I lay no stress upon the particular names here proposed In choosing them I have been influenced by such trivial considerations as the selection of a monosyllable to correspond with volt, and a dissyllable to correspond with ampere or coulomb

[With regard to Prof. Perry's footnote concerning college instruction and use of C.G.S. units, I suppose systems of teaching differ, but a senior student ought to be taught to deal with concrete quantities in so familiar a manner that no possible admixture of units can be any puzzle to him, nor involve anything worse than a little tiresome arithmetic.]

MECHANICAL UNITS.

There are several quantities in dynamics beside the joule and the watt for which brief names would be advantageous I do not propose to discuss these fully now, but the present opportunity might be utilised by agreeing to at least one unit, that of pressure—viz., the "atmosphere"; which might be defined as 10^6 C.G.S., or dynes per square centimetre, and stated to be equal to the pressure of a column of mercury 75 centimetres high at a specified temperature. The inconvenient pressure, 76 centimetres, might be spoken of as a Regnault atmosphere. I believe that a smaller unit of pressure, for instance, the micro-atmosphere or "barad," might also be usefully named. These pressure units will be useful for expressing energies per unit volume also, and the "barad," or whatever other name is decided on for the erg per cubic centimetre, is of reasonable magnitude for many purposes.

TRADE NOTES AND NOVELTIES.

Railway lighting is progressing Some time ago we were invited to inspect a railway reading lamp, and this gave considerable satisfaction, but we have not seen it in practice to any extent We believe such a lamp was shown a solitary one in the Entertainment Court at the Crystal Palace But now we learn that a special company has been formed, called the Railway Electric Reading Lamp Company, Limited (offices, 1 and 2, Great Winchester street), for the special purpose indicated, and we are informed that a contract, as result of two years' trials, has been made with the Metropolitan District

Railway for 10,000 reading lamps on their system The effect is shown in the illustration The gentleman in the corner reading the *Electrical Engineer* has, as is right, plenty of light, while the man reading the *Star* is in (physical) semi-darkness Each passenger can have his own light by putting a penny in the slot The apparatus was invented and perfected by M Tourtel. It is small, is only 5in by 3in, and after paying and pressing a knob, light burns for half an hour, sufficient for an ordinary suburban journey The lamp is 3 c.p., and can be turned about within certain limits The lamps will be placed under the hat-rail four in each compartment 16 to 20 lamps per carriage, all connected in parallel with a small set of accumulators by mains under the carriage. The lamps take ⅔ ampere each at 12 volts The battery is specially designed, consisting of six cells coupled in series, having a capacity of 72 ampere-hours They are enclosed in a strong wooden case, furnished with handles for easy removal, and duplicate sets are provided for each train A charging station is to be erected at Mill Hill Park, and sidings will be made for trucks for recharging the cells. Each truck will carry 28 batteries in four rows of seven, and each set of seven will be charged in series, with three series in parallel to the dynamo. The charging current will be 30 amperes (10 amperes per set) at 100 volts, the engine power for the whole being only 16 h.p. to 20 h.p. The cells will be distributed early in the morning, each charge being sufficient for two days. This method of distribution certainly has the advantage of being profitable, as each lamp taking 10 watts, for 1,000 watt-hours the company might receive 200d., or 16s. 8d., and this without cost of laying underground mains" As the railway company do not pay, and the average man will prefer electricity to a tallow candle no one is likely to object. The scheme is an interesting one, and let us hope will be a thoroughly successful one.

READING.

The following scheme for Corporation electric lighting works was brought before the Reading Town Council on Thursday last week -

A meeting of the committee of the whole Council (24 members being present) was held on Tuesday to consider a report from the Special Committee on the subject of electric lighting appointed by the Council on the 8th July, in consequence of a notice then submitted and proposed application by the Reading Electric Supply Company for a provisional order authorising the company to construct works and supply electric energy for lighting, motive power, and all public and private purposes within the borough. A letter was submitted from Messrs H and C Collins, solicitors to the company enclosing a copy of a letter from the Board of Trade, on the subject of the application by the company for a license under the Acts, to which the consent of the Council was recently given. The Board of Trade wrote that under circumstances explained they were not prepared to entertain the company's application for a license, but considered that the promoters should proceed by provisional order. The Special Committee met on the 21st July, and having considered the matter instructed the borough surveyor (Mr A E Collins) to prepare a report as to a suitable scheme to be embodied in a provisional order, and to obtain the assistance of an electrical engineer

At a meeting of the Special Committee, on Tuesday, a joint report was presented by Mr. J A. McMullen, A.M.I.E.E., and the surveyor, as to what would be a suitable scheme to be embodied in a provisional order, if the Council should determine to apply for such an order. We extract the following from the report -

"In considering the question of the advisability of the Council constructing and operating its own works for the supply of electrical energy, there are a few points worthy of especial attention The borough of Reading occupies such a good position in the financial world that it is enabled to borrow money much more cheaply than a company. The Council in carrying out works would not be tied in any way to buy the machinery or other plant of any particular manufacturer, but would be able to buy on the best terms The first object of the Council in constructing and operating works would be to supply energy at the lowest possible charge, due regard being paid to the ratepayers as distinct from consumers whereas with a company the first consideration would be that of dividend With works constructed and operated by the Council it is extremely improbable that establishment charges would approach the amount of such charges were the works in the hands of a company. The Council, as owners, would avail themselves of all improvements or economies in the generation or distribution of energy, and advantages gained thereby could be shared between the ratepayers and the consumers in the fairest possible manner. With regard to the general advantages of electric lighting in such a town as Reading, where good gas (16 candle) is sold at such a reasonable rate as 3s. per thousand cubic feet, the words of Prof Henry Robinson were quoted The cost of production per unit varies with the amount used With a generating plant capable of working 5,000 16 c.p. lamps at once it is estimated from the results obtained from existing installations, that the number of units sold would be [illegible] per annum The cost of producing electricity on this scale would be 3½d per unit, exclusive of interest and sinking fund, but including coal, oil, petty expenses, repairs, supervision, and [illegible] Interest and sinking fund would represent 1½d per unit, so that if 6d. were charged there would be a net profit of 1d per unit With a plant capable of supplying 10,000 16 c.p. lamps at once the cost of production would only be 2½d. per unit, or, including sinking fund, 3½d. per unit The Corporation could then supply at 4d. or 4½d and yet make a profit Electricity at 4½d. per unit is, light for light, equal to Reading gas at 4s. per 1,000 cubic feet With its enormous advantages it is always found that people are anxious to adopt the new illuminant at prices much higher than

previously paid for gas. Most London companies are charging 8d. per unit, equal to about 7s. per 1,000 cubic feet of gas, and yet their generating plants are taxed to their utmost capacity. At St. Pancras and at Bradford the local authorities are highly pleased with the result of their enterprise."

The district in Reading can be so selected as to be a very satisfactory one from the electrical and from the commercial points of view. The Corporation are in possession of what at present can be described as waste land in rear of St. Giles's Mill, which is eminently suitable for a central station. For so compact a district as that proposed for the area of compulsory supply, the best and safest system to adopt is the low pressure continuous current method, working on the three-wire system. [Reasons given.] The estimate is for a system of house-to-house supply on the above principle in the streets mentioned below: Friar-street, Blagrave-street, Valpy-street, The Forbury, West-street, Broad-street, Oxford-road (to Howard-street), St. Mary's Butts, Bridge-street, Southampton-street (to Crown-street), Crown-street, London-road (to King's-road), King's-road (to London-road), Queen's-road, London-street, Duke-street, King-street, Butter Market, High-street, Market-place, Minster-street, Gun-street, Castle-street, Cross-street. Should it be found necessary to extend the system of distributing mains in any direction, this can be conveniently done, and the pressure kept constant at the distant points.

Details having been set out, the report continued: The total cost of the scheme for house-to-house supply would be £37,000, including: Central station buildings, for 10,000 16-c.p. lamp plant; engines, dynamos, boilers, accumulators, testing and measuring instruments for 5,000 lamps; conduits under streets for 10,000 lamps; conductors under streets for 5,000 lamps. To increase the above house-to-house plant to the 10,000-lamp capacity would cost about £15,000, making the total cost of a 10,000-lamp plant £52,000. If it be considered desirable to light the streets named in the following list with 40 arc lamps, the additional cost would be £3,000, if the work were done concurrently with the house-to-house supply scheme, namely: Bridge-street, St. Mary's Butts, West-street, Friar-street, Market-place, Crown-street, Queen's-road, High-street, Broad-street, King-street, Duke-street, Southampton-street (to Crown-street), London-street, King's-road (to Eldon-road).

No amount has been estimated as the value of the site for the central station, that selected being the open almost waste land at the back of St. Giles's Mill. This land is Corporation property, and if detached from the mill it is not probable that the rental value of the mill would be materially reduced. The committee having considered the whole matter and consulted with the borough engineer and Mr. McMullen thereon, resolved to recommend as follows:

That the Council do not consent to an application by the Reading Electric Supply Company for a provisional order, but do determine to make application to the Board of Trade authorising the Council to supply electricity within the borough, and that the town clerk and the borough engineer, with the assistance of Mr. McMullen, be directed to take the requisite steps with a view to such an application being made in due course.

The committee approved the report, and recommended that the committee of the whole Council do meet again on September 8 next, and recommended to the Council that the committee be empowered to determine finally at that meeting as to the course to be taken by the Council on the subject.

The MAYOR moved and the DEPUTY MAYOR seconded the adoption of the minutes of this committee.

Mr. WELLMAN proposed an amendment that the question of the electric lighting of the town be considered at a public meeting of the Council instead of in committee. The matter was a very important one, involving an initial cost of at least £50,000.

Alderman KING seconded.

The amendment was unanimously agreed to.

LEGAL INTELLIGENCE.

LANE FOX v. THE KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY.

The Lane Fox Patents.

Judgment was given on Wednesday upon this appeal against a decision of Lord Justice (then Mr. Justice) A. L. Smith, sitting as a judge of the Chancery Division for Mr. Justice Romer during the illness of that learned judge. The action was brought by Mr. Lane Fox to restrain the defendant company from infringing the plaintiff's patent (No. 3,988, of 1878, for "improvements in obtaining light by electricity and in distributing and regulating the electric currents for the same, and in the means and apparatus employed therein." Mr. Justice A. L. Smith gave judgment for the defendants, holding that the patent was bad on the grounds that the complete specification did not conform to the provisional, that the invention, as described, could not be made to work, and that, if it could, no sufficient information was given as to how it was to be made to work. His Lordship, however, said that had the plaintiff been able to surmount the above difficulties, and had he established that by his invention he could have brought about what the Attorney-General said he could, his Lordship would have held that the plaintiff's invention was the subject-matter of a patent, that it had not been anticipated, and that the defendants had infringed it. (*Vide* the *Times* of March 31st last and the *Times* Law Reports, vol. viii., p. 467.) The plaintiff appealed. The appeal was argued at the end of June and the beginning of July by the plaintiff, on his own behalf, and by Mr. Roger Wallace (with whom were Sir H. Davey, Q.C., and Mr. Finlay, Q.C.), for the defendants. At the close of the arguments the judgment of the Court was reserved.

The Court now dismissed the appeal.

Lord Justice Lindley read the following judgment: This is an appeal by the plaintiff against a judgment of Lord Justice A. L. Smith dismissing an action brought for the infringement by the defendants of a patent belonging to the plaintiff. As usual in such cases, the defendants denied the infringement, and denied the validity of the plaintiff's patent, on the ordinary grounds of want of subject-matter, want of novelty, want of utility, insufficiency of the specification, and, in addition to these, the defendants contended that the nature of the invention, as described in the provisional specification, was not the same as that described in the complete specification, at any rate after it had been amended and put into its present form. Lord Justice A. L. Smith decided in the defendants favour on the last point, but he also came to the conclusion that the invention, as described, could not be usefully worked; and that the directions to work it were insufficient. He, however, decided the other points in favour of the plaintiff, and held that, if the patent had been valid, the defendants would have infringed it. A cross notice of appeal was given by the defendants, and the whole case was argued at great length before this Court by Mr. Lane Fox in person on the one side, and by Mr. Wallace, as counsel for the defendants, on the other. The Court was supplied with a printed copy of the shorthand writer's notes of the evidence taken in the Court below, of the arguments of counsel on the trial of the action, and of the judgment of the learned judge. All these I have carefully read and studied since the argument in this Court was closed. The plaintiff's patent, as described in his original specification, was for "improvements in obtaining light by electricity, and in conveying, distributing, measuring, and regulating the electric current for the same, and in the means or appliances employed therein." The provisional specification was filed on October 9, 1878, and the complete specification was filed on April 9, 1879. Owing to subsequent disclaimers and amendments, which it will be necessary to examine more carefully by-and-by, the only part of the patent which has to be considered is that relating to the distribution and regulation of electric currents for purposes of lighting. In order to understand the nature of the plaintiff's invention and the objections taken to the validity of his patent, it is necessary to ascertain what was the state of knowledge as regards electric lighting in 1878. This is by no means an easy matter, for since that time much has been learned, vast improvements have been made, and the progress has been so fast, and yet so gradual and continuous, that there is great danger of supposing that what is plain and well known now was plain and well known then. The evidence given in the case shows that the following matters were well known in 1878: First, that electricity could be used for lighting purposes; second, that the arc or Brush light was known and in course of being perfected; third, that incandescent lighting was foreseen as possible and probable, and that many persons were trying to discover how to effect it; fourth, that electric generators, and what are now called dynamos, were well known; fifth, that Planté's secondary batteries capable of being charged by an electric current, and of storing electricity (*i.e.*, of remaining inert), and of giving electricity out when wanted, were well known and had been used for arc lighting; sixth, that the voltage of the electric current given off by such batteries could be increased or diminished by adding or removing cells; seventh, that in order to obtain and maintain an electric current a complete conducting circuit was necessary; eighth, that for currents of low tension the earth itself might be used for a return conductor; ninth, that "earth," or "an earth," was a technical expression used to denote any suitable return conductor; and, tenth, that any competent electrician would know that, if in any particular case he could not use the earth itself as a return conductor, some other return conductor would have to be provided. On the other hand, the evidence shows that in 1878 it was not known how to construct an incandescent electric lamp for any generally useful purpose. It was not known to be important for the purpose of lighting with such lamps that the current supplying them should be kept at a constant pressure of about 100 volts; nor was it known that good results for incandescent electric lighting could be obtained by using secondary batteries, such as Planté's, in conjunction with dynamos. Further, in 1878 dynamos did not work so smoothly as they do now, and some better method of regulating the action of the engines used to drive them was necessary, or at least desirable. Lastly, it was not known that, for lighting large districts with incandescent lamps with electrical currents of high tension, the earth could not be used as a return conductor. Such being the state of knowledge in 1878, the plaintiff claims by his patent to have done three things which were new and useful: viz., (1) he claims to have invented a lamp which would answer the purpose; (2) he claims to have invented a method of keeping the E.M.F. of the current in the mains constant at about 100 volts; (3) he claims to have invented a method of better regulating the engines which drive the dynamos. The lamp has been since replaced by cheaper and better ones, and has been disclaimed. The regulator has become unnecessary by reason of improvements in engines and dynamos, and has been disclaimed, but it was a very important part of the

plaintiff's original invention. There remains the invention for keeping the E.M.F. of the current in the mains constant. This invention is the one which has to be considered in this action. An invention is not the same thing as a discovery. When Galvani discovered the effect of an electric current from his battery on a frog's leg he made a great discovery, but no patentable invention. Again, a man who discovers that a known machine can produce effects which no one knew could be produced by it before, may make a great and useful discovery; but if he does no more, his discovery is not a patentable invention. "Britain v. Hirsch" (5 Pat. Cas., 232), "Harwood v. Great Northern Railway Company" (11 H.L.C., 654), "Horton v. Mabon" (12 C.B.N.S., 437), "Saxby v. Gloucester Waggon Company" (7 Q.B.D., 305). He has added nothing but knowledge to what previously existed. A patentee must do something more; he must make some addition, not only to knowledge, but to previously known inventions, and must so use his knowledge and ingenuity as to produce either a new and useful thing or result, or a new and useful method of producing an old thing or result. On the one hand, the discovery that a known thing, such, for example, as a Plante battery, can be employed for a useful purpose for which it has never been used before is not alone a patentable invention; but, on the other hand, the discovery how to use such a thing for such a purpose will be a patentable invention if there is novelty in the mode of using it, as distinguished from novelty of purpose, or if any new modification of the thing or any new appliance is necessary for using it for its new purpose, and if such mode of user, or modification, or appliance involves any appreciable merit. It is often extremely difficult to draw the line between patentable inventions and non-patentable discoveries, but I have endeavoured to state the distinction as I understand it, and so far as is necessary for the purposes of the present case. I have, of course, been guided by the previous decisions on the subject, and especially by "Harwood v. Great Northern Railway Company" (11 H.L.C., 654), which is the most instructive of them all. I have been induced to make these observations in order to apply them to the question, whether the plaintiff's invention is anything more than a discovery that Plante's cells can be usefully employed for incandescent lighting. If it is not, his invention will not be the subject matter of a patent. What, then, is the nature of his invention as described in his original specifications? It certainly is not for the mere use of Plante batteries in connection with dynamos. It is for the use of them as described, which is a very different matter. His Lordship referred to the provisional and complete specifications, and continued: I cannot read these specifications without coming to the conclusion that the plaintiff thought he had discovered how to overcome one of the greatest difficulties in incandescent lighting. He points out that the E.M.F. of the electric conducting mains should be kept constant at about 100 volts by means of dynamos and secondary batteries, used as described at various places, and in conjunction with the regulator, which, he says, is necessary. That is his discovery and the nature of his invention as stated by himself. It is not put in this simple form; it is mixed up with the mode of carrying the invention out. The plaintiff not merely discovered that Plante's secondary batteries could be usefully employed for incandescent lighting, but he showed the importance of keeping the E.M.F. in the mains constant at the best voltage, and he claims to have shown how, practically, the desired result could be obtained, which no one knew before. As regards the nature of the invention as originally described, and as regards its being the proper subject matter for a patent, my decision is in favour of the patentee, provided always that his invention proves practicable. This accords with the view taken by Lord Justice Smith. But this view of the plaintiff's invention is of no use to the plaintiff, for neither the defendants nor anyone else use this invention as it was originally described. The plaintiff now claims something very different, viz., the use of secondary batteries in conjunction with dynamos for the purpose of keeping the E.M.F. constant in the mains at about 100 volts. Lord Justice Smith held this to be an invention very different from that originally described, and he also held that if this was the plaintiff's invention it would not work without modifications and precautions which the plaintiff never pointed out. I agree with him on both points, and I will take the last first. It is, I think, clear that no one had ever shown or professed to show how to produce this desired effect before 1878. Many prior patents were referred to by the counsel for the defendants to show want of novelty in the plaintiff's invention, but there is no trace in any of them of any method of keeping the E.M.F. in a main constant at any particular voltage, nor was that the object of any of them. I dismiss them all with that short observation. I pass from the novelty to the utility of the alleged invention and to the sufficiency of the specification for carrying it out. The utility of the alleged invention depends not on whether by following the directions in the specification all the results now necessary for commercial success can be obtained, but on whether by such directions the effects which the patentee professed to produce could be produced and on the practical utility of those effects. Can it be said that the invention as described in the amended specification was in 1878 a practically useful addition to the then stock of inventions? To judge of utility the directions in the amended specification must be followed, and, if the result is that the object sought to be attained by the patentee can be attained and is practically useful at the time when the patent is granted, the test of utility is satisfied. Utility is often a question of degree, and always has reference to some object. Useful for what? is a question which must be always asked, and the answer must be, useful for the purposes indicated by the patentee. See per Lord Chief Justice Tindal in "Cornish v. Keene" (1 Webst. Pat. Cases, 507); Edison v. Holland (6 Pat. Cas., 243); "Badische Anilin Fabrik v. Levinstein" (12 App. Cas., 712, 719, 720). An invention may be useful as indicating the direction in which further progress is to be expected, and yet that same invention may be useless for any other purpose; useless, that is, as an invention without further developments and improvements which have not occurred to the patentee. This is, in my opinion, the real truth with respect to the plaintiff's invention as now claimed by him. He made a distinct and important step in advance. The plaintiff was the pioneer, he showed others the road to be followed, but he did not give the traveller the information necessary to enable him to travel on it. There were difficulties to be overcome which the patentee did not foresee, and against which he naturally made no provision. There is an enormous mass of conflicting evidence upon the possibility of obtaining practically useful results by following the directions contained in his specification. Much of the evidence adduced against the patentee merely goes to show that by following the directions in the specification you cannot produce such good results as are produced by the defendants. This, obviously, is wholly immaterial. But there is, besides, a great deal of evidence to show that an electrician of ordinary skill would not have produced any useful result in 1878, if he simply followed the directions contained in the specification, as amended, with such variations only as an electrician of ordinary skill would have known how to make in 1878. So much more can be done now with a Plante battery than was suspected in 1878, that I have found the greatest difficulty in coming to a conclusion on this all-important question, and I much regret that we had not the assistance of an expert in electrical science. I have studied the whole evidence with all the care I can bestow upon it, and have come to the conclusion that the plaintiff had not, in 1878, invented what he now says he had—viz., a practical method of keeping the E.M.F. in the mains constant at about 100 volts, by means of secondary batteries and dynamos used simultaneously as described. The evidence adduced by the plaintiff shows that something like his invention can be worked on a small scale, and to a limited extent, when it is not necessary to charge the [illegible] so as to produce a high pressure when the lamps are connected with the main. Prof. Barrett's evidence as to what he did in his own laboratory for six years shows this; and it must be borne in mind that for a time he used water pipes and the earth as a return conductor, and showed them to be sufficient. But his voltage was low; his dynamo produced a current at a tension sufficient for his lamps, without the aid of secondary batteries, and he used his batteries as reservoirs rather than as regulators. Moreover, Prof. Barrett did not produce these results earlier than six or seven years ago, when much more was known about what could be done with Plante batteries than was known in 1878. The other cases in which the plaintiff endeavoured to prove that his invention was practically succeeded will be found to have involved considerable important departures from his invention as described. The installation for Lady Conyers' ball is the best case the plaintiff has, but there the batteries were taken charged, which is a very important matter. The defendants have, in my opinion, succeeded in proving that the lamps will be destroyed, if, whilst they are connected with the main, the batteries are charged at a sufficient voltage to work for any useful purpose. This objection to the patent goes to the root of the plaintiff's alleged invention. The objection is said by the plaintiff to be based upon the erroneous assumption that the batteries must be charged and emptied to an extreme extent. "Charging" and "discharging" are, no doubt, relative terms, to be understood within reasonable limits, and a man intelligent enough to seize the idea of the patentee would perhaps know, in a general way, that the E.M.F. could be regulated and kept approximately constant without excessive charging or discharging, and the brightness or dimness of the lamps would be his guide. But, conceding this, I think it proved that high charging is necessary to keep the E.M.F. constant and at anything like 100 volts, and, if necessary, it is not disputed that the lamps will be destroyed if the batteries are charged when the lamps are on, unless precautions against this cause of failure are taken. None, however, are indicated in the specification. I think it proved that a small variation in pressure in the main will cause current to go into, or come out of, the secondary battery, for a very short time. But this is not enough for practical purposes. High charging being necessary, it is, in my opinion, proved that the plaintiff's invention will not work without switches, and these are not mentioned in the specification. Upon this point there is much conflicting evidence, attributable, in great part at all events, to the ambiguity of the term "switching." It was known before Plante invented his secondary batteries that the voltage of primary batteries could be increased or diminished by increasing or diminishing the number of cells. The mechanical means of doing this is called "switching," and Plante himself pointed out that the voltage of his secondary batteries could be increased or diminished by similar means. Regulation, to some extent, takes place without switches. It is admitted by the defendants' own witnesses that the batteries have a steadying effect for a short time; they act as regulators to some small extent, and Prof. Barrett has produced satisfactory results in his laboratory with low voltage without switches. In Lady Conyers' case there were no switches, but there was no dynamo at work. On the other hand, the evidence convinces me that, for practical lighting with an E.M.F. of about 100 volts, and with dynamos, batteries and lamps all in use, switching is essential, and that no ordinarily competent electrician would have known, in 1878, how to keep the E.M.F. in mains constant at about 100 volts without further instructions than the plaintiff gave him. The plaintiff's claim to have invented, in 1878, a practically useful [illegible] keeping the E.M.F. in the mains constant at about 100 volts

whilst the dynamos are running and the batteries are being charged and the lamps are on, cannot, in my opinion, be sustained. This is the broad ground on which the patent, as amended, must be held invalid, and this was the ground on which Lord Justice Smith condemned it on its merits. Having arrived at this conclusion, it is unnecessary to consider the objections taken to the specification on the ground that the directions about the earth were misleading; and the direction that the cells of the batteries should have very large conducting plates was too indefinite. I have hitherto made no allusion to the plaintiff's regulator, but this was, in my opinion, an essential part of his original invention. He says in his original specifications that it is necessary. Necessary for what? The context shows that it was necessary to keep the E.M.F. in the mains constant. This was a mistake, and the regulator, and all that was said about it, has been disclaimed and struck out by amendment. But the effect of this is entirely to change the nature of the invention as described in 1878, and to enlarge it, which is not permissible. See "Gaulard and Gibb's Patent" (6 Pat. Cas., 215). In the original specification the plaintiff drew a marked distinction between storing and regulating; the secondary batteries were for storing, the regulator was for regulating. It is true that storing involves of necessity a certain amount of regulation; but, over and above such regulation as is necessarily incidental to storing further regulation was said by the inventor, in 1878, to be necessary for his invention. Between 1878 and 1883 he discovered that the regulator was not wanted, and that everything could be done by secondary batteries as used in 1883, by which time dynamos and switching had been greatly improved. He accordingly disclaimed the regulator. I am satisfied that the plaintiff had no idea that he could do without the regulator when he obtained his patent. He learnt it afterwards; and by disclaiming the regulator and amending his specification in 1883, as he did, the plaintiff essentially changed the nature of his invention for keeping the E.M.F. in the mains constant. The claim to the use of the batteries as reservoirs had a definite meaning in the original specification, but it has a different and much wider meaning in the specification as amended in 1883. The plaintiff is now really claiming a patent for the mere use of Planté's batteries in conjunction with dynamos. Such a patent would not have been valid unless the patentee had done something more. He must have shown how the two were to be successfully worked together. But assuming that a patent for such an invention might have been obtained, the plaintiff's patent was not granted for any such invention. The effect, therefore, of the disclaimer and amendment made in 1883 has been to destroy the validity of the plaintiff's patent, if it ever could have been made to work. Upon this point again I agree with Lord Justice Smith. It is needless to consider the question of infringement. I will only add that if the plaintiff's patent could be upheld as a patent for the use of secondary batteries in combination with dynamos, then the defendants would obviously have infringed his patent. But unless his patent can be upheld to this extent, no infringement has taken place. Convinced, as I am, that the plaintiff made a great step in advance when he suggested the application of Planté's batteries for the purposes of incandescent electric lighting, I feel bound to hold his patent invalid, on the ground that it was granted for an invention very different from that which he now claims to have protected, and on the ground that it was not in 1878 useful for the main purpose for which it was intended—viz., the practical lighting of large districts, and upon the ground that his specification was insufficient to enable an electrician of ordinary competence and skill in 1878 to carry it out without further experiments and invention, as distinguished from mere practice and increased dexterity and skill. The appeal, therefore, must be dismissed with costs, in the usual way.

Lord Justice Lopes said that he agreed, and had nothing to add.

Lord Justice Kay read a judgment to the same effect.—*The Times.*

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The half yearly general meeting of this Company was held last Friday at Winchester House, Mr. C. G. Mott presiding.

The **Chairman**, in moving the adoption of the report, stated that during the past half year the steady increase in their traffic had continued, and the position of the Company had decidedly improved. They had carried in the past six months 2,813,000 passengers, or about 400,000 more than in the same period of 1891, and their season ticket holders represented an additional 100,000 passengers. He considered this increase especially gratifying, remembering the curiosity which would be naturally shown in such an undertaking at the outset of its working, and also the large amount of traffic which they obtained through the omnibus strike in the first half of 1891. The receipts, too, had increased from other sources besides passengers—rents, etc.; and the proportion of the expenses had decreased from 79 per cent. in the first half year of their working to 76 per cent. in the second half and to 70 per cent. in the past half year. He hoped the decrease in the expense would continue until they came down to a really satisfactory figure. In the first half year of their working their earnings paid their expenses and their debenture interest; in the second half they were also able to pay the full dividend on their preference shares; and in the past half year they were able to pay a dividend at the rate of ½ per cent. per annum on their ordinary shares and to carry forward a larger balance than they brought forward. He wished their progress was more rapid, but they must remember that all sound businesses had to be worked up by slow degrees and by hard work and good management. He believed there was no better and more permanent mode in which capital could be invested in this country than in a purely passenger line in the metropolis if the cost of the line were commensurate with the probable income to be derived from it. The amount at the credit of profit and loss account would have sufficed to pay a dividend on the present occasion at the rate of ¾ per cent. instead of ½ per cent. on the ordinary shares, but the Directors had thought it much more in the interest of the Company to carry forward a larger balance. He then went into the details of the accounts and of the working of the past half year, and stated that their expenses per train mile had been reduced from about 9d. in the first half year of their working to 7·7d. It had to be remembered that, in addition to the working of an ordinary railway, they had the lifts and the hydraulic apparatus for taking their passengers to and from the surface to their trains, and this involved considerable difference in the cost of working their undertaking. During the past year a joint committee of the two Houses of Parliament was appointed to consider the best method of dealing with the various electric and cable railway schemes in the metropolis proposed to be sanctioned by Parliament. The committee reported strongly in favour of these schemes, both as to their construction and their working by electricity; and they suggested that in future it would be desirable to give to such schemes easements under property where they did no damage at a small cost without the necessity of following the lines of the streets. If this suggestion were approved by Parliament much more direct and better railways could be constructed at a diminution of cost. The Bill promoted by this Company for extending their line to Islington and getting rid of the inclines under the river could not be proceeded with further than the second reading in the House of Commons owing to the dissolution, but it was carried over to the present session, and, with other private Bills, would be proceeded with at its present stage.

Mr. Sampson Hanbury seconded the motion.

The **Chairman**, in answer to questions, stated that the attention of the Directors was being closely given to the question of adding to the accommodation of the line and of improving the service generally.

The motion was adopted, the dividends were declared, and resolutions were also passed sanctioning the issue of debenture stock to the extent of the Company's authorised borrowing powers (with the view to converting the present terminable mortgage bonds into perpetual debenture stock), and approving the issue of a further £5,000 of the preference shares created by resolution dated June 30th, 1891.

BUSINESS NOTES.

Great Northern Telegraph Company.—The receipts for the month of July were £23,900.

City and South London Railway Company.—The receipts for the week ending Aug. 7th were £919, against £822 for the same period of last year, or an increase of £97.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,771.

Personal.—We understand that Mr. C. E. Spagnoletti, the electrician to the Great Western Railway, has resigned that appointment, and has accepted a seat on the Board of the Phonopore Company, Limited, as managing director. He, however, continues consulting electrician to the Great Western Railway.

Burglar Alarms.—Orders for the West-end, in electric bell and fire and burglar alarm department, are reported by Messrs. Evans, Stewart, Palmer, and Co., of Carnaby-street, to be unusually numerous this holiday season. This firm have recently fitted up Westley-Richards, the gunmakers, of Bond-street, with electric light.

Asbestos.—The Lords of the Admiralty have again awarded the United Asbestos Company, Limited, the contract for the supply of all asbestos goods required in the Royal Navy during the ensuing 12 months, the principal articles being "Victor" block packing, "Victor" metallic packing, and hard spun yarn packing for glands, "Victor" metallic sheeting, tape, rings, ovals, etc., for steam and hydraulic joints, asbestos millboard, asbestos tape, covering for steam pipes, etc.

Pioneer Telephone Company, Limited.—An extraordinary general meeting of the Pioneer Telephone Company, Limited, will be held at Winchester House (Hall 174), Old Broad-street, on Tuesday next, August 16th, for the purpose of considering, and, if thought fit, passing the following resolution—that is to say, "That the Company be wound up voluntarily." Should the above resolution be passed by the required majority, it will be submitted to a subsequent extraordinary general meeting for confirmation as a special resolution. The meeting will also be asked to pass a resolution fixing the amount to be paid to the Directors by way of remuneration for their services.

Liverpool Overhead Railway Company.—The Directors report that during the past half year fair progress has been made with the construction of the railway along the whole line of docks, and only 61 spans of the main structure are required to complete it, while the permanent way is laid as far as the viaduct is finished.

The electrical generating station is far advanced and the engines are in course of erection. The railway, it is expected, will be completed in October. After deducting interest on amount paid in advance of calls £60, and administration expenses £401, a balance is left to the credit of net revenue account of £720. The Directors have obtained an Act of Parliament providing inter alia for an extension of time for completing the railway, and authorising the construction of certain extensions at the north and south ends of the line.

Companies of the Month.—The following electrical companies have been registered during the past month:

Electrical Company, Limited, £5 shares	£15,000
J. C. Howell, Limited, £5 shares	25,000
Lithanode and General Electric Company, Limited, £1 shares	100,000
Railway Electric Reading Lamp Company, Limited, £5 shares	100,000
Richmond (Surrey) Electric Light and Power Company, Limited, £5 shares	50,000
Theatre Electrical and Specialities Production Company, Limited, £1 shares	5,000
Universal Arc Lamp Syndicate, Limited, £1 shares	3,000

Telephone Company of Ireland, Limited.—The report of the Directors of this Company for the year ended December 31st, 1891, states that a supplementary statement for the half year ended June 30th, 1892, is also presented, pursuant to clause 56 of the articles of association, which requires that the accounts shall be made up to a date not more than four months before the annual meeting. The Directors regret the delay that has occurred in the issue of the report, but the expiry of the two master patents in December, 1890, and July, 1891, rendered it desirable that all outstanding questions and accounts between this Company and the parent company should, so far as possible, be finally disposed of. Save as to a sum of £395 18s. 5d., the accounts between the two companies are now agreed to December 31, 1891, and are duly certified. All the telephone companies subsidiary to the parent company have now, with the exception of this Company, been absorbed by the National Company. In the event of an amalgamation being ultimately decided upon as preferable to a separate company for Ireland, the Directors will endeavour to effect it upon such terms as shall be just alike to this Company as to the National Company. Having regard to the probability of capital being immediately needed to meet developments, the Directors consider it prudent to keep a substantial cash balance available, and they do not, therefore, propose to pay the preference dividend, or any dividend on the ordinary shares at present, but the preference dividend being cumulative its payment is only postponed. The balance standing to the credit of the net revenue account, as upon December 31, 1891, including the balance brought from last account, amounts to £5,363, which the Directors propose to allocate as follows: To the credit of the reserve fund, £370 (being 10 per cent. of the net profits of the year), carrying forward the balance of £4,993 to credit of the current year. The balance to credit of net revenue on June 30 was sufficient not only to pay the whole of the preference dividend, but leave a substantial sum for division amongst the ordinary shareholders.

PROVISIONAL PATENTS, 1892.

AUGUST 2.

13932. **Improvements in telephone switchboards.** John William Yates and Harry Thornton Yates, 16, Commercial street, Sheffield.

13989. **Improvements in telephones.** John W. Gibboney and Elihu Thomson, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

13996. **Improvements in electrical generators.** William Henry, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

AUGUST 3.

14035. **An improvement in electric incandescent lamps.** Josef Pinter, 52, Chancery lane, London. (Complete specification.)

[illegible]. **An improved process and apparatus for the purification of sewage, and the production of alkalies, chlorine, ferric chloride and electric energy.** Walter Walker, 132, Adelaide road, London.

14043. **Improvements in arc lamps.** Walter John Hubert Jones, 6, Lord street, Liverpool.

14044. **Electrodes for secondary batteries.** John Corry Fell, 1, Queen Victoria street, London. (William Morrison, United States.) (Complete specification.)

14056. **Improvements relating to electric motors.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (William Stanley, jun., and John Forest Kelly, United States.) (Complete specification.)

14060. **Improvements in dynamo electric and electro-dynamic machines.** Alphonse Isidore Gravier, 191, Fleet street, London.

AUGUST 4.

14064. **A continuous direct electric current machine and motor.** William Aldred, 5, Brightside bank, Brightside, Sheffield.

14089. **Improvements in dry batteries.** Carl Christian Losenberg and John von der Poppenberg, 4, Moorfields, Fore street, London. (Complete specification.)

14096. **Improvements in automatic electric arc lamps.** George Henry Church, 21, Cockspur street, London.

14102. **Improvements in or connected with electrically applying railway brakes.** William Phillips Thompson, 6, Lord street, Liverpool. (Otto Berndt, Germany.) (Complete specification.)

14124. **Electrical machinery and apparatus for excavating and removing coal or other minerals, partly applicable to other purposes.** Frederick Hurd, 23, Southampton buildings, Chancery lane, London.

AUGUST 5.

14160. **Electric apparatus for working the elevating and training gear of guns and the lifts for their ammunition.** George Sylvester Grimston, 28, Southampton buildings, Chancery lane, London.

14180. **Improvements in or connected with electric batteries.** John Laskey Dobell, 57, Chancery lane, London.

14181. **Improvements in or connected with electric batteries.** Charles Percy Shrewsbury and John Laskey Dobell, 57, Chancery lane, London.

14189. **An improved method of and apparatus for distributing alternating electric currents.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (William Stanley, junior, and John Forrest Kelly, United States.) (Complete specification.)

14193. **Improvements in or relating to electrically controlled valves.** Adolf Franke, 46, Lincoln's inn fields, London.

AUGUST 6.

14199. **A new and improved form of electric testing instrument.** Arthur Albert Day, 80, Queen Victoria street, London.

14206. **Improvements in or connected with electric batteries.** John Laskey Dobell, 57, Chancery lane, London.

14217. **Automatic electric heat alarm.** Fred Sumner Palmer and Leonard H. Deasle, 70, Wellington street, Glasgow. (Date applied for under Patents Acts, 1883 sec. 103, 9th January, 1892, being date of application in United States.) (Complete specification.)

14229. **Improvements in incandescent electric lampholders.** Herbert Stone, 55, Market street, Manchester.

14239. **Improvements in electricity meters.** George Hookham, 7, New Bartholomew street, Birmingham.

14250. **Improvements in secondary batteries.** Sigmund Adolf Rosenthal and Villeroy Comey Doubleday, 77, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1891.

12019. **Carbons for electric arc lamps.** Wise. (The Rheinische Fabrik für Elektrische Bogenlichtkohle; W. Gradelbach.)

12150. **Magneto electric time-pieces.** May.

13362. **Dynamo-electric machines.** Forbes.

15407. **Galvanic batteries.** Cohen.

15579. **Electric switch and cut out.** March.

17697. **Electric telephonic transmitters.** Graham.

1892.

6007. **Cells for electrolysing chloride solutions.** Parker and Robinson.

10367. **Connections and terminals for electric wires, etc.** Sanelle.

10762. **Electric lamps.** Weaver and Manypenny.

11032. **Insulating supports for electrical conductors.** Harris.

11119. **Electric switches.** Broadway.

11147. **Secondary batteries.** Lloyd.

11154. **Welding metals electrically.** Thompson. (Coffin.)

11316. **Electric alarums.** Van Vianen.

NOTES.

Paris Storage Cars.—We understand that the recent trials with accumulator cars in Paris have been very successful.

Berlin Exhibition.—The proposal to hold an international exhibition in Berlin in the year 1900 has been abandoned.

Walsall.—The poles for the electric tramcars at Walsall will be lighted by electricity and will have small refuges round the bases.

Turin.—It is proposed to utilise 5,000 h.p. in Turin by means of multiphase currents electrically transmitted from the waterfalls, 35 miles distant.

Dublin.—Additional tests have been made at Dublin, and great admiration has been expressed by the promenaders in the streets at the beauty of the electric light.

Dundee.—The Dundee Gas Commission have appointed Mr. W. H. Brownlee, of Dundee, to the position of electrical engineer to the municipal central electric station.

Brownhills.—The streets of Brownhills, near Walsall, are not yet lighted at all, and the inhabitants desire to have light. The question is to be discussed at next meeting.

Cable Rates.—The cable tariff to Australia has been increased by 9d. a word from October 1 next, the Press rates remaining as before. The rate to New Zealand is reduced to 5s. 3d. per word.

Dulwich.—More area to light is wanted by the Crystal Palace District Electric Supply Company, and the Camberwell Vestry have consented to an extension including a certain small area in Dulwich.

Chatham.—The Chatham Town Council have appointed a committee to consider and report upon the desirability or otherwise of acquiring by purchase the Chatham Electric Lighting Company's interests and works.

Electric Cable Railways.—The full text of the report of the Commission on Electric and Cable Railways (Metropolis) has just been issued by Messrs. Eyre and Spottiswoode, price 1s. 5½d., in the shape of a Blue-book.

Bath.—The inspector at Bath is to report fortnightly on the state of the public electric lamps. He is to have a testing apparatus for meters also erected on his premises at a cost of £40—the fixed fees for testing to go to the inspector.

Colchester. — The Colchester Town Council have unanimously decided, on the advice of their Electric Lighting Committee, to take the necessary proceedings for obtaining electric lighting powers for carrying out their own central station.

Fishing by Telegraph.—A timely telegram this season from the offices of the Scottish Fishery Board brought the boats to the right spot in Orkney, and a catch worth £3,240 was made. But for the telegraph this would have been impossible.

Kingston.—A proposal is to be placed before the Corporation of Kingston-on-Thames and the Surbiton Commissioners for supplying their districts with the electric light, generated by means of water power at one of the weirs upon the river.

South Shields.—The new police buildings, including two courts, now being built at South Shields are to be lighted by electricity. The County Borough Council have placed the contract, which provides for upwards of 200 lamps, in the hands of Mr. T. Harding Churton, of 5, South-parade, Leeds.

Maidstone.—At the next meeting of the Maidstone Local Board the members will be asked to appoint temporarily an electrical engineer to superintend the installation of the electric light. A lighting station will probably be erected in the Fair Meadow, at an expenditure of from £10,000 to £12,000.

Fleetwood.—The Fleetwood Improvement Commissioners have been granted an extension of time for their provisional order for three months. Fleetwood has been nibbling at the question for a long time. It is an improving and progressive town, and we hope that the project for electric light will be carried out.

Mannheim.—If anyone wishes to compete with German manufacturers on their own ground, there is a chance at Mannheim, where the central station is to be illuminated, and tenders are asked by the end of October. The specification (in German) can be obtained for 4s., from the Direction, Staats-Eisenbahnen, Karlsruhe.

Coast Communication.—At the last meeting of the Leith Chamber of Commerce a letter was read from Mr. Sandford Fleming, London, a delegate of the Board of Trade of Ottawa, regarding a proposed enquiry and report on the best means of promoting direct telegraphic communication throughout the British Empire.

Trowbridge.—At Trowbridge, where the Sanitary Authority wish to keep the powers in their hand, Mr. Chapman has recently explained that they did not wish to adopt a dog-in-the-manger policy. If a company made proposals they were willing to consider them. Mr. Haden said he had suggested premises at Cradle Bridge as suitable, but the question is left to the inhabitants to decide.

An Electric Canoe.—An electric canoe has been constructed by Messrs. Woodhouse and Rawson, who have named it the "Flash." The canoe is 18ft. long by 3ft. 9in. beam, with a draught of about 1ft., and will carry four persons. She is built of mahogany, and is fitted with a ½-h.p. motor, energised by Epstein accumulators. At the trial which took place recently, the "Flash" attained a mean speed of over six miles an hour.

Steam Yacht.—The magnificent yacht "Roxana," belonging to Mr. Singer, is now at Tenby. The "Roxana" is the largest yacht in the United Kingdom. She was formerly owned by the Prince of Luxembourg, and is lighted throughout by electricity. At present she is anchored close to the Castle-hill, and is a beautiful specimen of marine architecture. The projector light has caused much interest in the town.

Alicante.—An interesting installation has just been started at Alicante, in Spain, by Messrs. Siemens and Halske, of Berlin. Three Otto gas engines, made by Deutz, of Cologne, driven by Dowson gas, are used to run the dynamos, which are of the usual Siemens continuous-current type. This is the first central station, as far as we are aware, which is run by Dowson gas. The station is only small, but is none the less important.

Blue Electricity.—Some time ago a certain Count Mattei, of Italy, brought out a system of cure-all by means of phials of "red and blue electricities." He managed to get a large amount of approval, and to impose on a number of earnest men, but a strict investigation by a medical committee showed the result, as expected, to be a complete failure. It would be a very good thing if a little of the same kind of publicity could be given to the electropathic belts.

Arcing on Switchboards.—A jet of live steam is the latest addition to switchboard apparatus. In countries where the danger of a burn-out from lightning is serious,

the lightning arrester is a useful, and indeed necessary adjunct, but the flash sometimes causes an arc to be formed by the dynamo current following the discharge. To turn on live steam is found the best way to put out the arc. The use of a zinc alloy, as recently suggested, for the contacts would, however, probably be more practical.

Leith.—The new co-operative flour mills at Leith, when completed, will be capable of an output of about 4,000 sacks of flour per week, and the warehouse will hold about 40,000 sacks of flour. The machinery, which is to be of the newest description, is to be provided by Mr. Simon, Manchester. The buildings will be lighted throughout by the electric light. Last Saturday afternoon about 15,000 persons assembled at Leith Links and took part in a procession in honour of the laying of the memorial-stone.

Hysteresis.—An abstract in the *Journal* of the Institution mentions some interesting experiments by W. Kunz on the effect of temperature on hysteresis. With equal maximum induction the hysteresis loss distinctly diminishes with increase of temperature. In a piece of soft iron the loss per cubic centimetre was 23,190 ergs when cold, 19,180 ergs at 530deg. C. (dull red), and 21,640 when cold again. Steel showed a diminution of hysteresis of about 20 per cent. when raised to 100deg. The methods of measurement are not given.

The "Unique" Switch.—We note that Mr. A. P. Lundberg is now prepared to grant licenses for the manufacture, on royalty, of his latest patent switches—the "Unique"—both in England and most of the principal foreign countries, and we understand the terms are very favourable to responsible firms. We are pleased to learn that the "Unique" switches are rapidly coming into favour, and have already been taken up by two firms on royalty. In cases where we have seen them used they have given much satisfaction.

Berlin Electric Railway.—The proposal for the electric underground railway in Berlin is making progress. The line is to be equipped by the Allgemeine Company, and will be 30 miles long. There will be two generating stations connected together by mains, and using 500 volts. There will be 48 trains, each with three carriages, running at one time, the fare for any distance being 10 pfennig (1¼d.). The trains will run on a three minutes' service. The success of the London line is responsible for the proposed introduction of the system into Berlin.

Mansion Lighting.—Newbold Revel, the country seat of Mr. H. E. Wood, is to be electrically lighted with about 500 incandescent lamps, distributed between the house, stables, swimming-bath, gymnasium, and racket court. The installation is being arranged by Mr. A. A. C. Swinton, and the plant, which will comprise two Cornish boilers, two Parsons steam turbines and dynamos, and a large battery of "D. P." accumulators, will be similar to that recently completed by Mr. Swinton for Lord Durham at Lambton Castle, and to that at present being laid down by him for Mr. Clayton, M.P., at Chester.

Coatbridge.—Edinburgh waits, but Coatbridge, if not following Glasgow and Aberdeen (who have their own installations), at least expects the electric light before long. The master of works has reported that the Scottish House-to-House Electric Lighting Company had taken off a feu on the Dundyvan Estate for the purpose of erecting works for supplying electric lighting in the burgh. An application was made by the company for permission to open the streets for the purpose of laying the main wires, but the Council decided to ask for a plan of the streets they wished to open up before further considering the matter.

Coventry.—A quarterly meeting of the Coventry City Council was held on Tuesday, the mayor (Mr. Singer) presiding. A report from the Electric Lighting Committee, adjourned from February, was brought up for further consideration, accompanied by letters from Mr. A. Bromley Holmes, electrical engineer, Liverpool. The ex-mayor (Alderman C. J. Hill) moved that it be referred back to the committee, with instructions to take Mr. Holmes's letters into consideration, and recommend to the Council any scheme for the electric lighting of Coventry. Dr. Fowler seconded the motion, which was adopted.

Waterford.—The electric lighting scheme for Waterford is lost, and the gas company gain the day. The gas company sent in an offer to light the city with lamps consuming six cubic feet per hour at £2. 17s. 6d. per lamp for a period of five years. Further, they undertake not to apply for a provisional order for electric light except in case some other company so doing, when it might be worth while to protect their powers. The electric light company's offer was £22 per arc lamp a year, the same as before. After an uproarious meeting the resolution was carried, by twelve to six, that the gas company's offer be accepted as final.

National Physical Laboratories.—*Ever since Prof.* Oliver Lodge mooted the subject at the British Association last year, the proposal for the establishment of a national physical laboratory has been looming before us. Dr. Arthur G. Webster, in an article reproduced in the *Electrical World* of August 6, takes up the matter from the American standpoint, and urges the need for such an institution in that country. His proposals will be read with interest by those who are pressing the question forward. A considerable part of the article consists in an account of the German Reichsanstalt established under the superintendence of the veteran *savant*, Prof. Hermann von Helmholtz.

Testing Instruments.—Apparatus for testing and for experiment is likely to be more and more in demand both for installation work and private use, now that electricity is studied as a "subject" in all good schools. Mr. R. W. Paul, of Hatton garden, is making quite a name for himself in the department indicated. He has read several good papers before the Physical Society, has produced several ingenious instruments of his own, and makes those of Prof. Ayrton and others. Mr. Paul's instruments may become well known, and to help this result he has issued recently a neatly-printed catalogue embodying many good types. The special set of apparatus for Prof. Ayrton's "Practical Electricity" is a good idea and worth attention by technical schools.

Yarmouth.—The Yarmouth Town Council have decided to ask Mr. Preece to report upon the tenders they have received for a central electric installation. These tenders, from six different firms, have been opened, and vary from between £5,000 and £6,000 up to £[illegible]. This variation is no doubt due to the fact that no actual specification was issued, but each firm was left to suggest and send in their own plans. The smaller schemes embody a small plant at low cost, while the larger schemes embody a full project for lighting. The surveyor will get out an analysis of the tenders, and Mr. Preece's advice will be taken, as we have said, upon the general bearings of the scheme. The thorough way in which this was done at Worcester will lead the Yarmouth Council to feel themselves in very safe hands.

Installation Efficiency.—Careful experiments have been carried out with the electric plant at the Argenteuil railway station by the French Edison Company. The boilers are two of Weyher and Richemond's, engines are

speed (85 revolutions), 35 h.p. to 50 h.p., by same makers, driving Edison dynamos, 115 volts and 240 amperes at 950 revolutions. The lamps comprise 30 arcs of 6 to 12 amperes, and 95 incandescents of 10 c.p. and 16 c.p. The two extreme arcs are three-quarters mile apart. The test with all lamps and an added resistance gave a total of 26,400 watts absorbed. The output was 460 watt-hours per kilogramme of coal, or 209 watt-hours per pound, equal practically to 5lb. of coal per supply unit. This was 30 per cent. better than specification, and is a result that may be regarded as very satisfactory.

Collier-Marr Telephone.—We drew attention some time ago to the Collier audible telephone, which apparently promised to be an improvement over ordinary forms. This telephone has been improved, and is now being manufactured, works having been fitted up with suitable plant and machinery. A company has recently been formed, with a capital of £100,000, with offices at the works, Derby-street, Oxford-road, Manchester, to carry out the patents. Orders have already been received from the General Post Office, the Canadian and Indian Telegraph Departments, the Great Northern Railway, the General Electric Company, and the Corporation of Bradford, and important negotiations for the supply of instruments have been opened with other English railway companies. These orders and negotiations are the results of successful trials of the instruments.

Fire-Alarm Box.—What shall be the solution to the "false alarm" problem of the Metropolitan Fire Brigade? We can hardly think that the man in the street who sees a fire will enter a chamber like unto the torture-maiden and consent to be left locked in until the policeman or fireman come to his rescue and let him out. Nevertheless, such is the bold and ingenious idea embodied in the combination street alarm station now on view at the Fireman's Exhibition. No signal can be given until the door is shut, and then it is locked upon the alarmist, whose only consolation is that he can telephone at his ease to all the fire stations in London. What a fate if the fire were to spread and roast him alive in the alarm station! We prefer the French method of telephones in a box. Persons giving false alarms will ring a bell, but would hardly be so likely to send a deliberate telephone message.

Electric Light in Italy.—Now that Rome is about to utilise the cascades of Tivoli for the purpose of obtaining the electric light, it is surely time, remarks the *Daily Graphic*, that the great cities of England were bestirring themselves if they do not wish to be left altogether behind in the race to secure the advantages of electricity. The Englishman who enters Italy with the fixed persuasion that his own country must necessarily be far ahead of Italy, as regards electric lighting, is astonished, if he enters Italy by the Riviera, to find that Genoa has its streets almost wholly lighted by electricity. He moves on to Florence, and if he is set down by night at the railway station he sees no gas lamps anywhere as he drives to his hotel—only the electric light. He visits Venice, and there he finds the Square of St. Mark's lighted by electricity in a way in which no public space in London is lighted. Even at Rome itself the electric light is already in the streets in the neighbourhood of the railway station. We may do it better than they in Italy, perhaps, when we really set about it, but we cannot now be first.

Coast Communication.—The Royal Commission to enquire into the means of communication between lightships and the shore have visited Liverpool this week on a tour of inspection. The Commissioners, accompanied by the chairman of the Mersey Harbour Board, the marine surveyor, and other port officials, made a trip down the Channel inspecting the Crosby, Formby, and north-west lightships, with a view of ascertaining the best and most effective means of establishing a system of communication between these vessels and the lifeboat stations ashore, in order to secure the readiest assistance for vessels in danger and to promote the saving of life. The Commissioners will inspect the lighthouses off Liverpool, and thence proceed to Kingstown *viâ* Holyhead, to hold a conference with the Irish Light Commissioners. After visiting the light stations on the east coast of Ireland they will go to Milford Haven, and visit the lighthouses on the South Wales coast and the south side of the Bristol Channel, voyaging thence round the Scilly Isles, along the south coast of England to the Thames, and northwards to Edinburgh, to hold a conference with the Northern Lighthouses Commissioners.

Barnsley.—We trust the Electric Lighting Committee at Barnsley will not cease their endeavours to introduce the electric light, in spite of their recent rebuff, which is for the second time. The committee—who consist of the mayor (Alderman Blackburn), Alderman Wray, Councillors Haigh, Jackson, and Wheelhouse—have considered carefully their report, and recommended the adoption of a central electric station for the town, with Mr. Bromley Holmes as engineer, but their recommendation was rejected. Mr. Raley is already converted, but thinks the best way would be to leave the lighting to a private company, in spite of Bradford and St. Pancras. Dr. Halton was the principal opponent to the scheme, on the score of expense. The first scheme was to cost £24,000, and this one £18,000, which he still regarded as too much; though his principal objection apparently was the cost of the lamps—3s. 6d.—which he had seen would soon be a shilling each only. The worthy doctor did not seem to realise that this saving would not affect the present question of plant at all, though it would reduce the future charge for lamps. The councillors who want converting are Aldermen Bailey, Woodcock, Marsden, and Pigott; Councillors Taylor, Sykes, Webster, Hinchliffe, Fountain, Halton, Frith, Holden, Bailey, Tyas, Tinker, and England. Electrical engineers have a twelvemonth to accomplish their conversion.

Windsor.—The electric lighting question at Windsor is in a little bit of a fix. The Town Council some years ago spent £80 in considering the matter, and decided to support the application of the Windsor Electric Lighting Company, but this company has somehow or the other not succeeded in obtaining all the capital they require. (Why is there not some means of obtaining a little more capital, if the project is in businesslike form?) The company now want to give up part of their powers and light two streets only. The following is the report of the Electric Lighting Committee presented at the last meeting by Mr. Dyson, the chairman: "Your committee recommend the Town Council to reply to the letter of the Board of Trade that the Council have no objection to the company laying down their distributing mains in the two streets named in the application of the company, provided that the Board of Trade are satisfied that the company have sufficient capital and means to carry out the same, and to provide for the continuance of the supply of electricity for a reasonable period, and, further, that conditions be imposed compelling the company to lay down distributing mains and supply energy over the whole area of supply in a fixed time." Mr. Dyson asked to be excused from moving the report, as it was his opinion the lighting should remain in the hands of the town. Mr. Soundy then moved its adoption, saying the committee

wereunanimous except for the chairman. Mr. Burt explained they wished to throw the onus of seeing the thing well done on the Board of Trade, though the town clerk remarked they had power themselves to fine the company £5 a day for non-fulfilment of the order. Mr. Dyson said he was anxious to avoid another monopoly, and moved an amendment that the Council do not agree to the modification of the order already granted, but the motion to adopt the report was carried by nine votes to five.

Southport.—A special meeting of the Southport Town Council was held on Tuesday under the presidency of Councillor A. Pilling, deputy mayor, for the purpose of considering the recommendation of the Gas Committee with regard to the adoption of the electric lighting system by the Corporation. Estimates showing a proposed capital outlay on the scheme for £27,060 were submitted. This is to cover the cost of buildings and distribution mains sufficient for 6,600 16-c.p. incandescent lamps, or 12,000 lamps of 10 c.p., and for the generating plant for the supply of 1,900 16-c.p. incandescent lamps, or 3,700 lamps of 10 c.p. The committee recommended the adoption of these estimates, and that 8a. 1r. 18p. of land behind the gas works at Crowlands be purchased out of the capital moneys of the gas estate, of which land 3a. 1r. 18p. be used for the purposes of electric lighting, subject to the approval of the Local Government Board. Alderman Hacking, chairman of the Gas Committee, moved the adoption of the minutes containing these recommendations. He recounted the circumstances which had led to the Corporation to decide upon becoming the electric lighting authority of the town, and to undertake the work itself instead of letting it to contractors. He also explained that the Council had already resolved to adopt the high-tension system, and to place the installation on a site adjoining the gas works at Crowlands. The scheme they now recommended embraced two services, one for the supply of electricity to the residential district having Hesketh Park as its centre, and the other to the business section of the town. The energy generated by the plant at the Crowlands station would be distributed at 2,000 volts, but this would be reduced at the transforming stations to 100 volts. Councillor Travis seconded the motion, and other members having spoken in general commendation of the scheme, the minutes embodying the committee's recommendations were unanimously agreed to.

Prescot.—The electric lighting question is occupying the minds of the people of Prescot very fully at the present moment. The British Insulated Wire Company, of that town (of which Mr. C. H. Yeaman is engineer), has made an offer to provide an installation and light the town by electricity. Their first estimate not being considered acceptable, the company have now made a second amended and fuller offer. Prescot, they said, was favourably situated for a central station, and they offer to provide a mixed installation of 12 arc lamps of 2,000 c.p. and 70 incandescent lamps of 12 c.p. actual each for the sum of £350 a year for a five years' contract. The arcs would be kept alight till midnight, 50 of the incandescents until the usual hour, and the other 20 until the daylight came on the scene. They also asked for 4½ per cent. on £400 for lamps and fittings. The Board held a long sitting to discuss this offer, and both cost of running and the candle-power of the lamps came in for explanation. Mr. Yeaman was in attendance, and explained that £350 a year would cover everything for five years, but had no reference to the item of 4½ per cent. on the outlay for lamps and fittings. If the contract were not renewed at the end of the five years, the company could not consider their plant sufficiently deteriorated as to be valueless in itself, though it would then be practically valueless to them, and a five years' contract would thus not recoup them for their expenditure. In consideration of this fact they asked 4½ per cent. on the £400 at the end of the term if the contract then came to an end, but the item would not be charged at all if the Board and the company were still satisfied with each other. The £350 would cover "everything incidental and necessary to the lighting of the town." There was another item of 4½ per cent. required elucidating, and Mr. Yeaman explained that in cases where the company was asked, for æsthetic or other reasons, to lay cables underground against their ordinary practice, they would ask the Board to pay interest on the cost of such an unusual outlay. Mr. Atherton, the managing director of the company, eventually consented to forego these items of 4½ per cent. The gas lighting at present costs £260 a year, plus a man at 18s. a week—£304 a year for gas—so that the increase will not be serious. Mr. Yeaman promised to have the light started in a month. An amendment to accept the gas company's tender found no seconder, and the resolution to give the contract to the Wire Company was passed. The authorities in St. Helens are understood to be watching the movements of Prescot.

The Brain Covered-Conduit System.—*Closed* conduit systems for electric traction are slowly *evolving* themselves, and a new one is now before *the engineering* and tramway world. We have seen Mr. Lineff's ingenious idea of the serpentine underground contact-maker in practice, and a British Association paper gave prominence to the scheme. We have heard little of it since—the telephone clauses, perhaps, were too hard. Mr. Wynn had his contact-boxes under every length, and his system is promised on a large scale shortly. Mr. Gordon, with the same idea reduced to a box every hundred yards, was taken up by Messrs. Merryweather, who, however, have not yet come to the stage of putting it down. The only conduit system at all a success as yet is that at Budapest, but that is an open slot conduit. Now, Mr. C. T. B. Brain, of Bee-buildings, South John street, Liverpool, brings forward an entirely different and most bold scheme, described in his pamphlet now before us, in which there is a combination of closed and open conduits. He has a small open conduit in which the conductor is laid, contact being made by a trolley wheel from the car. But the whole slot is covered in with a thick band of flexible metal, which effectually closes the slot and is capable of bearing the weight of many tons. The car in passing raises the flexible cover, making contact, of course, below, and lays the cover again lightly behind it, rolling it down by a projecting roller. Here is your solution—and an ingenious idea it is. Further, Mr. Brain appears to have tried his system thoroughly and practically during the past year—in rain, hail, and shine. Water and dirt cannot get in, and no one can raise the lid without extreme trouble. The ice cannot resist the shearing force of the rising cover, even in a hard frost. But most important of all, if it is necessary to inspect the conduit, all that is needed is to turn a screw on the car contact and send the car along and the whole cover is lifted and deposited on the roadway at the side. Repairs and inspection made, the car is run back and the cover settles into place. Really it seems an admirable idea, and if only practical in working we may have here the underground conduit problem solved. All kinds of turn-outs and switches have been, we are told, constructed and worked, and the system is stated to give every satisfaction on the experimental line. The cost of installing is small. All that is needed is to see it in action on some scale and

submitted to the tests of practical men. Mr. Brain claims his invention as the outcome of seven years' experience on Blackpool electric railway and elsewhere.

Varley Testimonial.—The committee who have the proposed Varley testimonial in hand have issued a statement, in which the life-long labours in electrical research of Mr. S. A. Varley are set forth. The following is a brief abstract. Born in 1832, he commenced the study of chemistry at the age of 14, and in 1849 experimented with hundreds of cells constructed with his own hand. In 1852 he entered the service of the Electric Telegraph Company, and was in 1854 appointed to the charge of telegraphs in Liverpool. He constructed an electric chronograph, and in the spring of 1855 took charge in the Crimea of the first field-telegraphs used in war. In 1858 he wrote "On the Electrical Qualifications requisite of Long Submarine Cables," and his opinions were endorsed by Faraday. In 1866 Mr. Varley discovered for himself the reaction or self-exciting principle of dynamos, and at that early date constructed his first machine of the pure dynamo type, now in South Kensington Museum. It was awarded a gold medal at the Inventions Exhibition. The controversy which subsequently arose on this invention may be held to have been fitly summed up by the late Robert Sabine, C.E. (son-in-law of Sir Chas. Wheatstone), in the following words: "Prof. Wheatstone says he was the first to complete and try the reaction machine. Mr. S. A. Varley was the first to put the machine officially on record in a provisional specification, dated December 24th, 1866, which was, however, not published until July, 1867. Dr. Werner Siemens was the first to call public attention to the machine in a paper read before the Berlin Academy on the 17th January, 1867" (see *Engineering*, November, 1877). In 1866 he introduced needle telegraph instruments with soft-iron induced magnetic needles, which have superseded the old form. In 1875 he became assistant manager at the works of the British Telegraph Manufactory, where the first Gramme machines constructed in England were made. There is scarcely a doubt that Mr. Varley's investigations at this period led to the invention of compound winding. Mr. Varley's *magnum opus* is the important part which he took in the invention and perfecting of the dynamo, perhaps the most striking invention of the century, and upon this his fame as a patient, conscientious, and earnest scientific investigator of the Faraday school will permanently rest. His researches were undertaken in the true spirit of science, and no thought of self-emolument has ever caused him to deviate from the path which he has pursued throughout an eventful, although eminently simple and blameless, life—a life in which self-denial and self-sacrifice have no small share. Like many men of genius, he was far ahead of the times and has lived to see others reap the benefit of his great discoveries. His nervous and retiring disposition has for years kept him from the busy haunts of men, and to the younger generation of electricians he exists only in name—a name, however, that will live as long as the dynamo is employed in the service of man. Subscriptions to the testimonial will be gladly received by the hon. treasurer, Mr. A. Stroh, 98, Haverstock-hill. Mr. R. E. Crompton is secretary, and the committee, commencing with the name of Lord Kelvin, includes nearly all the most prominent British electrical engineers of to-day.

Taunton.—At the quarterly meeting of the Taunton Town Council last week, the Electric Lighting Committee recommended that in case they purchase the electric company's undertaking the Council shall repay the cost of meters and transformers to customers. They also recommended that the company be asked to lay the mains for the proposed extension, the Council to pay the amount expended thereon. The Mayor moved the adoption of the report. He said it was quite understood that the transformers and meters—provided the negotiations were completed—would ultimately become the property of the Corporation, and in order to provide against any loss of time to persons wishing to take in the light, the Corporation should make the offer to take over the articles mentioned at cost price. The town clerk then read a letter from the electric light company, stating that the directors had passed a resolution to the effect that they would find the wire to supply the private lighting in the Staplegrove-road extension if the Council would excavate the trench and lay the public lighting wire. Mr. Meyler also read the following report which he had drawn up respecting the legal position of the Council on the matter: "I think it is advisable that the members of the Corporation should know how matters stand as regards their powers of treating with the Electric Lighting Committee for an extension of the lighting. The existing contract with the company provides that all posts and out-posts for lamps and wires be supplied by the Council, and it further states that all such alterations as may be required by the Council for their own convenience shall be made by and at the expense of the Council. At an interview with some of the directors of the company with the committee on the 30th May it was suggested that there should be an extension of the lighting, and that the Corporation should supply posts and lamps for such purpose; but at that time overhead wires were contemplated. On the 26th day of July, the Council resolved to extend the lighting by placing seven new lamps in the positions then mentioned. A question has arisen whether the Council have power to lay underground wires for the purpose of such lighting. I think they have. The contract provides that alterations (which includes such additions as these) shall be carried out at the expense of the Council. I understand that these wires cannot be utilised for private lighting, if, therefore the company wish to lay wires or mains for private lighting, the Corporation might fairly ask for a reduction in the charge per lamp for the new lamps, as the cost of the outlay connected therewith falls on them. The payments in respect of these new lamps must fall, in the first instance, on the general district rate. The Local Government Board may or may not include these payments in the loan, but I have never known them refuse to include amounts properly expended before the application has been made to them. It would have been better if all questions as to extensions could have been allowed to remain over until the purchase is completed, but if the majority of the Council think that there are circumstances which render it advisable to extend the existing lighting there is no legal difficulty in their doing so. I have received the draft contract from Messrs. Kite and Broomhead, and have, at their suggestion, agreed that it shall be settled between both parties by counsel, and we can, I have no doubt, agree upon some gentleman who is an expert in this special branch of the law." Alderman van Trump seconded the Mayor's motion. Alderman Spiller said the electrical firms in the town should have an opportunity of tendering for materials if it could be done. Councillor Sibley said that the cable proposed had been a great success at Exeter. The surveyor mentioned that the cost of the Staplegrove-road extension would be £69. 17s. 6d. for the cables and laying, and £141. 15s. altogether, with the lamps, poles, etc., complete. The report was then adopted, and the terms of the company respecting the laying of the new cables were accepted.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

VII.

(*Continued from page 74.*)

RESISTANCE, *continued.*

Wheatstone's Bridge and Resistance Box Combined.—The original form of Wheatstone's Bridge with long base board and stretched wire was found much too cumbrous for ordinary practical use, and the stretched wire was also liable to get damaged. On these accounts, therefore, the use of the Metre Bridge is now chiefly confined to laboratory testing and for educational purposes, although the simplicity and exactness of this method of measuring resistances was too apparent to allow the principle to be discarded in the construction of commercial instruments.

Fig. 8 illustrates diagrammatically the application of the Wheatstone's Bridge principle to the numerous and varied forms of apparatus included under the general title of Post Office Wheatstone's Bridges, so called because the compactness and portability of the arrangement render this class of instrument particularly suitable for testing the resistances of overhead and submarine telegraph lines, which at the time when this type of apparatus was first introduced, was almost the only kind of electrical measurement made outside the walls of scientific laboratories.

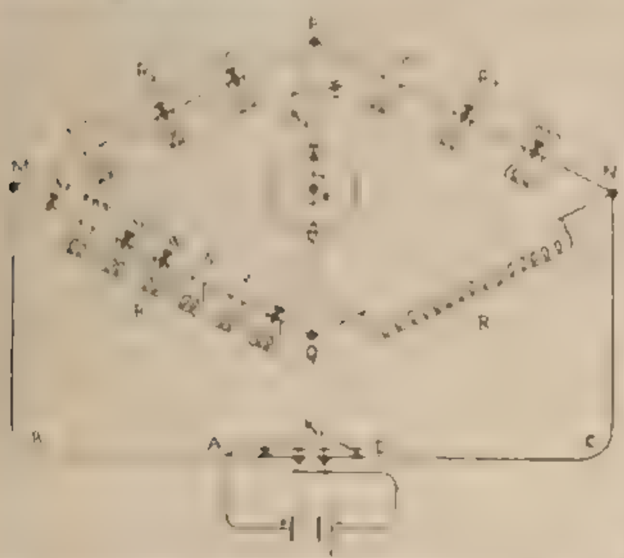

FIG. 8.—Theoretical Diagram of Post Office Wheatstone's Bridge.

In Fig. 8, the arms R_1 and R_2, which in the Metre Bridge were represented by the stretched wire and adjusted by the movement of the point P along it, here consist of two similar sets of fixed resistances. These usually comprise three coils each, as shown, of 10, 100, and 1,000 Ohms resistance respectively, although in some cases, where greater accuracy is desired, an additional 10,000 Ohm coil is added to each arm, and, again, in some of the less elaborate forms of the apparatus each arm has only two coils, one of 10 and another of 100 Ohms. With three coils in each of the arms P M and P N as represented in Fig. 8, and with a single plug removed from each, the ratio $\frac{R_1}{R_2}$ may be given any of the following values

$$100, 10, 1, \tfrac{1}{10} \text{ or } \tfrac{1}{100}$$

Other values may be given to this ratio by varying the number of plugs removed from each of the arms, but this is seldom done, owing to complications being thereby introduced into the readings. The arms P M and P N are usually known as the Ratios of the bridge.

R_3, the known variable resistance, which in the Metre Bridge was represented by a separate Resistance Box, is here incorporated in and forms the principal part of the combined apparatus itself. It is represented in the diagram, Fig. 8, in its most usual form, a set of plug resistance coils, of which, however, only a few are there shown. The combinations most commonly used are coils of :

1,	2,	3,	4,
10,	20,	30,	40,
100,	200,	300,	400,
1000,	2000,	3000,	4000 Ohms,

and to these is generally added an "Infinity" plug, which resembles all the others in outward appearance, but has no resistance coil attached underneath, so that it affords a convenient means of completely breaking the circuit altogether by simply removing the plug from its socket. The removal of any of the other plugs simply throws into the circuit an additional resistance equivalent to that of the coil bridging the gap from which the plug was removed, the current having now to pass through that coil and be retarded by its resistance, instead of simply passing through the plug, which offered practically no resistance whatever to it.

Another arrangement of the coils in R_3, somewhat similar to the one just given, is provided with the following resistances :

1,	2,	2,	5,
10,	20,	20,	50,
100,	200,	200,	500,
1000,	2000,	2000,	5000 Ohms,

with an "infinity" plug added as before. With either of the above arrangements, the maximum value which can be given to R_3, excluding the use of the "infinity" plug, is the sum of all these resistances, or 11,110 Ohms, and it may be made any exact number of Ohms less than this.

A third arrangement of resistances, although more economical in the matter of coils than either of the preceding ones, is little used owing to the difficulty of reading off the total resistance if it is at all high. In this case the coils are arranged so that their resistances increase in geometrical progression, each being the double of the one preceding it. The series usually starts with a pair of unit coils for convenience in testing, and ends with an "infinity" plug, as in the two former cases. Thus with a set of fourteen coils of 1, 1, 2, 4, 8, 16, 32, 64, and so on up to 4,096 Ohms arranged on this plan, the total resistance of R_3 may be made to take any value from 1 to 8,192 Ohms. The methods of constructing, adjusting, calibrating, and standardising these and other forms of fixed resistance coils will be considered later on.

It is sometimes desirable, in order to eliminate errors of instruments, etc., to have at hand a convenient means of reversing the current in the circuit, and a method of accomplishing this is shown diagrammatically at K_1 in Fig. 8. Here, if the right hand contact maker is depressed so as to touch the connection beneath it, the current flows from the positive pole of the battery, through the left hand contact maker, then past A and B to M, where it divides itself and flows through the arms of the bridge from M to N, then past C and D, and through the depressed right hand contact maker to the negative pole of the battery. If now the right hand contact maker is released and allowed to return to the position shown in the diagram, and the left hand one is depressed in its stead so as to touch in its turn the connection beneath it, the current from the positive pole of the battery will now flow through the right hand contact maker, past D and C to N, through the arms of the bridge from N to M (which is the reverse direction to the former case), then past B and A, and through the depressed left hand contact maker to the negative pole of the battery, thus again completing the circuit. This principle is embodied more or less in nearly every variety of reversing key. In the next paragraph are given a few examples of the numerous reversing and other keys and contact makers now in use for the testing of resistances and other similar purposes.

Keys and Contact Makers.—As a means of establishing contact between two pieces of wire so as to complete an electrical circuit the obviously easiest method, that of simply holding the two ends together so as to keep them in contact, is extremely inconvenient and unreliable, and a large number of keys and contact makers have been devised for this purpose. The forms of these vary with the special requirements for which they are constructed, and range from the simple contact maker, Fig. 9, with flat brass spring which establishes contact by being depressed on to a stud and breaks the circuit again on being released, to the somewhat complicated

conditions demanded by the very heavy suburban traffic of the metropolis. It has, however, been in a certain measure successful, as indicating the possibilities of electric traction on railways, and the economy to be effected by the use of iron tubular tunnels following the lines of streets at a sufficient depth below the surface to avoid sewers and pipes and disturbances to property. The result is that several Bills have been promoted during the last session of Parliament for the construction of similar lines in various directions. One of the most important of these is the proposed Great Northern and City Railway from a point near Finsbury Park Station on the Great Northern Railway to Finsbury Circus. It differs from the others in that it is intended to run the ordinary passenger trains from the main line of the Great Northern Railway to the heart of the City without change of carriage. To do this it is obvious that electric engines of much greater power are required than those at present in use on the City and South London Railway. It is claimed for this engine that it would fulfil all the conditions which this line demands, whilst, if made on a smaller scale, it would be more economical for working the traffic of the other lines referred to than those at present in use.

It is proposed to work on a central rail similar to that used in the Fell system, and to arrange the electric motors vertically, so that the driving wheels may be horizontal. The necessary adhesion is to be obtained by means of springs, which press the driving wheels against each side of the central rail. One great advantage afforded by this arrangement is that it enables the electric motors to be kept constantly running, even when the engine is stationary, thus avoiding the great loss of power incidental to the starting of the engines now in use. A friction wheel is interposed between each electric motor and its corresponding driving wheel in such manner that they can all be thrown in and out of gear at the pleasure of the driver. The electric motors, which are the most delicate part of the machine, are carried on a platform supported by the springs, and consequently are not subject to the shocks caused by inequalities of the road. Another advantage of this type of engine is that it can be constructed of any reasonable size, and may, therefore, be far in excess of the power of the largest steam locomotive, which is limited by the size of the boiler. The dead-weight also of this engine would be considerably less in proportion to that of the steam locomotive, as the tractive force is obtained by gripping the central rail and not by gravity. It is especially applicable to lines where the gradients are steep.

In all central rail systems a difficulty at once arises as to points and crossings. This has been overcome by a novel form of switch, which is illustrated by a working model. It is the patented invention of Messrs. Purdon and others. The description is as follows: The pieces of rail of similar section to that used for the central rail are curved to a suitable form, and coupled together by a special casting near each end; the two sections of rails are not in the same longitudinal plane, and each cross-piece is provided with a roller working upon a horizontal axis. At the centre of the length of the two portions of rail a casting is fixed, which is common to both, and is so formed that it rides freely upon a vertical pivot which is fixed to a sleeper or other suitable part of the permanent way. The two sections of rail which thus form a kind of rocking cradle are free to move upon the centre pivot, and the rollers at each end travel upon paths of a segmental form when looked at in the plan. In elevation the segmental paths are so formed that one section of the rail can be moved into position with, let us say, the main line track, but, when the rocking cradle is swung sideways the second rail, which, as previously described, is in different plane, is caused to rise during its swing, and complete the middle rail for the branch, or cross-over line. It must be understood that owing to the different level of the two sections, the portion which is not in use at any given time lies below the horizontal plane passing through the top of that which is in use.

The engine is provided with ordinary flanged wheels, as it is designed to meet the case of a railway where it is desired to haul ordinary stock, and where the curves are not sharp; but in the case of lines like the City and South London Railway before referred to, where the grades are steep and the curves very sharp, the carrying wheels need have no flanges, and the stock can be made to take very sharp curves—indeed, up to 50ft. radius without difficulty. This advantage of the central rail system, which is illustrated by the model truck exhibited, becomes very important in cases where it is desired to pass under streets which diverge at right angles, and also at termini, where a balloon-ended station will do away with the necessity for shunting operations or breaking of electrical connections.

THE DESTRUCTION OF LIGHTNING PROTECTORS BY RECENT MUNICIPAL LEGISLATION.*

BY W. H. PREECE, F.R.S.

The immunity of private houses from being struck by lightning is very marked, and this is considered to be due to the fact that the lead on our roofs, and the iron stack pipes that drain these roofs, connected as they are together, form admirable lightning protectors. Any charge of atmospheric electricity which may fall upon a house so protected is conveyed harmlessly away to the earth. Householders are now required to remove these pipes from direct connection with the drains, and to leave an air space between the end of the pipe and the grating of the drain. The result is that the electric conduction of the pipe is broken, the stack pipe ceases to be a lightning protector, and houses are left exposed to the dangers of atmospheric electricity.

The remedy is very simple. The pipe need not be entirely cut away: three-fourths of its circular section may be removed for the distance required; and one-fourth may be left to maintain the old electrical connection, or if the separation has been effected, then the stack pipe should be connected with the drain by a wire or rod so as to restore a path for the charge to the earth.

Householders are also now compelled to put up stack pipes to ventilate their soil-pipes, erecting above their roofs a metal tube forming a prominent object, exposed to the atmospheric charge, and terminating frequently in an earthenware pipe on the first floor. They are thus liable to be struck by lightning without offering any means of escape. They should be connected electrically with the earth either directly or indirectly through the stack pipes, which would then make them sources of safety rather than of danger.

SUBMARINE RELAYS.

The following note from the *Moniteur Industriel* seems sufficiently important:

M. Willot, inspector of telegraphs, has returned to Paris after two months in Algiers, which he has spent in experimenting on the submarine cables between Marseilles and Algiers. These experiments were carried out with the object of increasing the capacity of transmission and of rendering the service easier by means of apparatus analogous to that used in overhead wires. The experiments have given unhoped-for results. By means of a new system of relays invented by M. Willot, communication can now be maintained direct between Algiers and Paris, with Hughes and Wheatstone instruments, as easily as with overhead wires of the same length. The telegrams are received on a printed strip as on ordinary lines, and are not subject to the transformation now obligatory on submarine lines employing the mirror galvanometer. The tests carried out by M. Willot leave us no doubt as to the final success, and Algiers will, therefore, be shortly connected direct to Paris. Telegrams, instead of taking at the minimum 3½ hours and often three or four hours in sending, will now be transmitted in half an hour at most.

Electric Terms.—The second edition of Prof. Houston's "Dictionary of Electrical Terms" is meeting with much success.

* Paper read before the British Association at Edinburgh.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Other Places	4s. 10d.	...	9s. 11d.	..	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

STORAGE TRACTION FINANCE.

Determined efforts are being made, we are glad to hear, to put the accumulator traction problem on a thoroughly sound basis. We trust these efforts will not miss their aim for want of a little knowledge and enterprise. We can look back to the time when the "box of energy" came over from France and was tested by Lord Kelvin (then Sir William Thomson), the results of whose research resounded through the length and breadth of the world. If we have not yet achieved all that was expected by journalists from this discovery by Faure of the pasted cell—if boxes of energy are not as yet delivered around like milk to the door—we are getting near to this consummation, as witness the railway reading lamps recently mentioned, which are to be distributed in thousands all over the metropolis. In central station work no one can complain, in England at least, that the storage battery has not done good, honest service, creditable alike to the manufacturer and the electrical engineer. The storage battery for lighting has been a success. But how is it with the storage battery used for traction? Where are our large and well-filled cars in every great town driven by electricity? They are yet to come—and the difficulty, hitherto one of electrical engineering, is now one of finance. "Will it pay to run storage cars?" The answer, "Yes," is being pronounced with a more and more confident ring, and this notwithstanding the costliness of certain well-known experiments. The time for experiments is done. Away with them, and let us have good, large, straightforward contracts, in which each party is willing to take their share of the responsibility, and to guarantee the performance of their share of the work. The parties are willing. "Is there any just cause or impediment" to stand between the fulfilment of their wishes? is the question to be asked.

The history of storage traction in this country is bound up to a large extent with that of the pioneer line of five cars at Barking-road, and though there is no reason to give too much importance to this small and out-of-the-way line, yet the results there achieved necessarily have a direct bearing on the future employment of storage cars elsewhere. The contract between the General Electric Traction Company and the North Metropolitan Tramway Company at first was to run the cars and supply power and driver for the sum of 4½d. per car mile run. This contract ran for three years and, not paying, was eventually raised to 5½d. per car mile, at which rate the contract ran for one year. The question was lately raised whether the North Metropolitan Company would take over the installation, and, being a large company, instal a greater number of cars, which might then be run on a paying basis. This they did not see their way to do, nor yet to increase the number of cars. The offer of the traction company to run in the future these five cars only for 2d. a mile extra was refused by the tramway company, as it would make an addition of nearly £1,600 a year to the cost of running the line, and, notwithstanding the rise in the price of fodder, would exceed the cost of horse traction.

but they eventually agreed to pay another 1d., making 6½d. per car mile, and they also agreed to put the line in thorough order. The loss (if any) was, by a business arrangement, to be divided between the traction company and the storage battery company, who were equally interested in its success. For some little time the service had not been so good as it might have been owing to stoppages, due, it is said, to defects in the permanent way. These defects tried the axles—which themselves were not as strong as they should be—and when a breakdown did occur, it was not only on the car axle, but this breakage spoilt the motor armature. It is significant that both permanent way and axles were just that part of the line supplied by the tramway company and remaining under their control. After many requests the road was at last repaired, and since then all has gone well. Nevertheless, after preliminary *pourparlers*, after the permanent way was restored and the new agreement made ready, suddenly the tramway company, either being tired of the trouble or losing interest in the experiment, announced their intention to terminate the contract on September 1st. The directors of the traction company would not undertake to do anything further unless the contract was renewed for twelve months, and therefore withdrew the cars. This is how the matter now stands, and from the electric traction point of view several morals can be drawn. First, that it does not pay to run five cars only by electricity; secondly, it is not wise to run cars the axles and wheels of which (designed for horse cars) are supplied by the tramway company; and, thirdly, that a stringent clause must be inserted as to the thorough repair of permanent track when the traction is undertaken by a separate company on contract. These morals are plain and on the surface. The fourth moral, with reference to the cost of electric traction, is not so plain, and we will now proceed to draw it to the best of our ability for ourselves, our readers, and the tramway companies at large.

It seems that the companies are unwilling and unable to run the tramcars themselves by electric traction. Therefore, either the storage manufacturers must take up the running; or an independent financial company must take over the contract (as the Jarvis-Conklin Trust has done in America); or a separate electric tramway trust should be formed to buy and run the cars. This latter would no doubt be the best way if the money could be subscribed. It may yet be done, but for the present we may content ourselves with the consideration of the first case—a contract by the party manufacturing the cells. Now, we have the direct authority of Mr. Frank King, the chief engineer and manager of the Electrical Power Storage Company, that they, a powerful and responsible company, are now willing and ready to undertake the running and upkeep of electric storage cars for any tram line running more than twenty cars, for a price equal to two-thirds of the receipts. Not for five or ten cars, but for any reasonable number, say twenty or thirty cars. A large item in the cost of electricity is the salary of a superintending electrical engineer, and this would be no more for fifty than for five cars. On this condition, and without including expenses in connection of the permanent way, or the repair of the car bodies, but including all costs of running and maintaining the car equipments, for this the offer is 66 per cent. of the receipts. This may be an offer that the directors of tramway companies in our large towns may like to take up seriously. In many cases the offer would not mean any benefit, and again in others, where operations are on a large scale, the offer would naturally be likely to allow of considerable modification. But let us see what it means.

The receipts per mile last year for the North Metropolitan, for instance, on their whole system was 13·52d. per mile; the total expenses over all was 10·9d. per mile. Two-thirds of 13·52d. would be 9d. per mile, evidently no improvement on the present, where 10·9d. is the total cost, including permanent way, repairs and management. But this is for several hundred cars, and our quotation for twenty cars would be very considerably modified for this number. Take, now, the Birmingham central tramways. It will be interesting to give the comparative cost of the various methods of traction for the last year—for all four methods are in use on these lines. They are as follows—

	Receipts.	Expenses.
Steam	15·67d.	10·99d.
Horse	11·02d.	9·79d.
Cable	12·83d.	6·33d.
Electricity	15·15d.	9·90d.

The cable cars, it will be seen, are more popular than horse, and they cost much less to run. Steam and electricity both earn far larger returns, and cost not greatly over the horse traction—electricity being one penny per mile cheaper than steam. Take the returns for the horse traction in Birmingham, 11·02d. per mile run, to be typical of other tramways, as it may well be. Then, taking two-thirds of the receipts as the price to be paid for electric traction, we shall have an expenditure for running the cars of 7·35d. per mile run. It lays with the tramway companies to say whether the cost of power, management of cars, and upkeep of the power equipment is worth accepting at this price, bearing in mind, also, that electric cars are far more acceptable than the horse cars, and that one-third of the added profits would be obtained without risk on their part. We think it may be worth while; and when a still larger number of cars is taken, with a contract price still more favourable, the consideration may be all the more worth while. Meanwhile, it may be interesting to give the published figures of an American storage car line. This is the Eckington and Soldiers' Home Railroad, at Washington, of which Mr. G. S. Patterson is manager. The road has been working successfully for upwards of five months, and the figures are given as average cost and summary of results during that time:

Mileage of five cars per day	471 miles.
Mileage per day per car	94 miles.
Mileage in 150 days per car	14,100 miles.
Number of cells per car	264 cells.

Cost of running per car mile:

Charging, etc., of cells	2·00d.	4·5d. per car mile
Labour	1·50d.	
Mechanical supplies	·75d.	
Sundries	·25d.	

In this case no renewals have yet been made, but the estimate is stated to be based on renewal of batteries after six months, the batteries being expected to run 16,000 miles without repair. The cars run over one gradient of 150ft. in length with 4·7 per cent. rise, and another of 1,000ft. of over 10 per cent. rise. The cars are frequently loaded with eighty passengers without apparent overtaxing of the cars. The average run on a single charge is twenty-two miles, and each car makes five trips a day. Two 40-h.p. dynamos are used alternate weeks for charging. Without wishing to put too much stress on these figures, may we not ask whether English electrical engineers intend to be left behind in storage as well as in overhead conductor traction? Storage batteries are used here to a far greater extent than in America. We know their habits and their cost, and we surely can show now what can be done for electric traction by their means. Electrical engineers are, indeed, ready. What do the tramway companies say?

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RICHMOND (SURREY).

SIR,—I have forwarded to you a report of a discussion in the Borough Council of Richmond upon certain difficulties which have arisen between the Council (through their engineer) and the contractors (through their engineer) upon the question as to which are the best and most suitable plans to adopt for the purpose of supplying the borough with light by electricity. The engineer of the company appears to wish to adopt a plan which he considers best, and the engineer appointed by the Council obstructs the progress of the contract and is strenuously supported by the Council upon grounds set forth in the adjoined report. Would you through your valuable columns assist the residents of this borough to understand the position which they may probably be placed in should open rupture occur between the contractors and the Council, and litigation ensue, as the ratepayers of this borough have no means of knowing how their affairs are conducted in committee? The obstruction assumed by the Council and their engineer appears to be carried on through personal pique, as shown by classing the letter of the contractors as impertinent, when that letter appears to some simple folks as merely advocating a fair way of settling a question as to the best way of executing certain work; and the only excuse for calling the company's letter impertinent appears to be that the Council are told that their engineer is an obstructionist. It appears that rather than allow any of the well known scientific men, which have been submitted by the company to step in and solve the problem in question, the whole of the Council are unanimous in risking an extensive lawsuit, the cost of which may eventually fall upon the borough.—Yours, etc.,

W. J. WESTON.

Difficulties with the Electric Lighting Contractors.—The Electric Lighting Committee presented the following report: "The chairman reported that, acting under his instructions, the town clerk had written to Mr Baker, the solicitor of Messrs. Latimer Clark and Co., calling attention to the continued delay in submitting plans of the proposed buildings and otherwise, and read a reply received from Mr Baker, dated the 27th inst., intimating that the delay rested with Mr Shoolbred, the electrical engineer of the Council, who did not approve the plans submitted nor the system of mains desired to be laid by the company. Mr Shoolbred and Mr Murdock (the company's representative) were in attendance before the committee, and the subject was discussed at great length, but no result was arrived at. Mr Murdock was to report to the company his interview with the committee, and the town clerk was directed to reply to Mr Baker's letter."

Councillor Hensler moved the reception of the report, and observed that matters were now almost at a deadlock. Another letter had just been received from Messrs. Latimer Clark and Co.'s solicitors. The **Town Clerk** read this letter, which was as follows:

"22, Great George-street, Westminster, August 8, 1892.

"RICHMOND ELECTRIC LIGHTING.

"Dear Sir,—Referring to my letter of the 27th ult., and your reply of the 29th ult., I beg to suggest, on behalf of my clients, that as all progress in this matter has been stopped by the action of your engineer in unreasonably withholding his approval, a dispute or difference has arisen such as is contemplated by clause 21 of the contract, and that the same should be referred to a friendly arbitration. It would save expense and delay if one arbitrator only was appointed, and I give you as a choice of names, to any of which my clients would agree, the following: Mr W. H. Preece, Prof. Robinson, Prof. A. B. W. Kennedy, Dr. John Hopkinson, Dr. Bottomley, Mr C. E. Spagnoletti. You will no doubt agree with me that the arbitrator shall take into his consideration all the circumstances of the case, and also any extension of time that shall be granted for completion of the works. I trust you will do your utmost to expedite this arbitration as my clients are anxious to get the works (which might have been nearly completed by this time) in hand, and are very disappointed at the unreasonable objections raised by your engineer.—Yours faithfully,

"CHARLES EDWIN BAKER."

"F. B. Senior, Esq."

Councillor Hensler remarked that he need not say that whatever loss of time there had been had been entirely through the action of the contractors. The committee had facilitated them in every possible manner. Letters had been received as late as Monday evening, trying to get things passed through the Council next day without going to the committee. He begged to move that the letter be referred back to the committee with power to act therein. The **Mayor** asked if it was intended by the committee to refer the matter to two arbitrators. **Alderman Robinson** hoped that would not be done, and he did not think that the question of the delay should be submitted to the arbitrator at all. The questions relating to plant and the building might, he thought, be settled by their agreeing in a friendly manner upon one arbitrator. **Alderman Skrimshire** was sorry not to agree exactly with the object of the mover of the resolution. He knew a good deal as to the way in which these negotiations had been carried on. Had he been acting for Messrs. Latimer Clark, Muirhead, and Co., he should have been very sorry to have written such letters as had been written to the committee. If such a letter as the one just read had been written privately to himself he should have repudiated it without delay. It started by saying that progress with the work had been stopped through the action of the Council's engineer. If the letter were accepted that suggestion would be adopted to some extent, and there was not one word of truth in it. Progress had been stopped by the extraordinary action of Messrs. Latimer Clark and Co. themselves, right through. The committee had been more than anxious to fall in with their views, and those of the proposed company. Week after week and month after month, up to almost the very time when the work should have been completed—and it was not yet commenced—the most impertinent letters had been written, of which that just read was a sample. The Council ought not to treat upon a letter which began with a false statement. If it had said that "It is alleged by our clients that —" so and so, it would have been different. Surely the Corporation ought to stand by their engineer, who advised them what was the right thing to be done. He thought that the best thing that could happen for the interests of the town would be for the negotiations to come finally to an end. **Councillor Turpin** concurred. **Councillor Thompson** agreed. This was a most impudent letter, and he could not think that they ought to go to arbitration upon it. He should propose as an amendment that the matter be simply referred to the Electric Lighting Committee. **Councillor Hensler** accepted this suggestion. **Councillor Hilditch** did not see why the Council should go on at all in this matter. The letter was a most insulting one. He did not see why communications upon these matters of detail should go through solicitors at all; they should come direct from Messrs. Latimer Clark and Co. The **Mayor** said it was quite understood that the committee would not bind the Council to arbitration. **Councillor Hensler** agreed. It would report again to the Council.

THE CHICAGO EXHIBITION.

In our issue of the 15th of July we said that while the expense of exhibiting at Chicago was great, if the return, on the other hand, was likely to be at all commensurate, the trade should go ahead and combine to make a show worthy of a great industry, and not be content that it should comprise only a few paltry exhibits which, instead of leading the visitor to think of what he may expect to find in this country, is more calculated to cause him to think of what he may not expect to find. In the issue following we gave a copy of a circular which had been sent out by the secretary of the London Chamber of Commerce to the Electrical Section, with the object of ascertaining how far the members were disposed to support Mr. Preece's suggestion that a suite of rooms should be fitted up and

other two (Nos. 12 and 29) were H cells of the pattern described by Lord Rayleigh.

These cells were compared with the standard at the Cavendish Laboratory, with the results shown in Table II., which gives the differences between the four cells and the standard in hundred-thousandths of a volt.

Values of Berlin Cell Standard in ·00001 Volt.

Date.	July 26th.	July 27th.	July 29th.
Temperature.	16·1	15·9	15·9
Cell No. 69	− 15	− 18	− 14
„ „ 71	− 11	− 15	−
„ „ 29	− 36	− 35	− 36
„ „ 12	− 39	− 39	− 39

On July 29 cell No. 71 had been taken away.

Dr. Kahle kindly determined the differences between No. 69 and each of the other cells before they left Berlin. Values for these same differences can be obtained from the above Table II. We thus get Table III.

Table III.—Differences between Cell No. 69 and the others sent from Berlin.

Date and place of observation.	No. 71.	No. 12.	No. 29.
July 19, 1892, Berlin	− 2	29	29
July 20, 1892	− 4	28	25
July 21, 1892	− 4	25	26
July 26, 1892, Cambridge.	− 4	21	24
July 27, 1892	− 3	19	20
July 29, 1892	—	22	25

Thus the relative values of the cells as found at Cambridge are practically the same as those found at Berlin; while taking the E.M.F. of the Cambridge standards as 1·4342 volts at 15deg., that of the Berlin cells with porous pots is 1·43405, and of the Berlin H cells about 1·4338

The value actually found by Dr. Kahle for the E.M.F. of the porous pot cells is 1·4341 volts, so that the agreement is complete. In all the above it has been assumed that the resistance of 106·30 cm. of mercury is one ohm, and that the amount of silver deposited per second by a current of one ampere is ·001118 gramme.

The H form of cell in all cases examined at Berlin has a slightly lower E.M.F. than those with the porous pots, the difference being about ·0003 volt.

Appendix IV.

On the Standard Condensers of the Association, and on certain Resistance Coils.

BY R. T. GLAZEBROOK, F.R.S.

The report of the committee for 1890 contains as an appendix a very full account of the tests on the standard condensers belonging to the association. It was there stated that while the insulation resistance of No. I. was very high, that of No. II. was not completely satisfactory. No. II. was therefore taken to pieces and set up afresh. Its capacity and also that of No. I were determined afresh, using the commutator method described in the previous paper.

The following values were found :

Condenser No. I.

Date.	Capacity in microfarads.	Mean of each series.
December 23, 1890	·021059	
„	·021052	·021050
„	·021046	
December 29, 1890	·021044	

Condenser No. II.

Date.	Capacity in microfarads.	Mean of each series.
December 23, 1890	021396	
„	021392	·021395
„	021399	
December 23, 1890, afternoon	021365	
„ „	021399	·021389
„ „	021403	
December 29, 1890	021381	
„	021409	·021390
„	021389	
Mean of the whole	0·21391 microfarad.	

The different values in each series correspond to different rates of revolution of the commutator.

The value found originally for the capacity of No. I was ·021024 microfarad; it would appear therefore that it may be slowly increasing. The capacity of No. II has been changed by being taken to pieces and from ·022515 to ·021391.

The two condensers were also compared directly Assuming the value of No. I. to be ·021050, that of No. II. was found to be ·021390, practically the same value as that given by the commutator.

As a further check on the values, a mica condenser was compared with the two in the usual way. The values found were:

Date.	In terms of I.	In terms of II.
December 29, 1890	·5017	·5013
January 1, 1891	·5013	·5012

In March, 1892, the insulation of the condensers was tested by the secretary and Mr. A. S. Bowley. They were both found to lose rather less than 1/600 of their charge per one minute.

A divided condenser, Elliott No. 144 CLC No. 3 was compared. The results are interesting, as showing the effect on the capacity of the time of charging, and are given in Table III.

The first observation in each case, marked as 0", was made by connecting the galvanometer and then momentarily making the battery circuit for a very small fraction of a second. The observations on the condenser ·2 show that there has been no appreciable change in the relative value of the Standards I. and II. The observations throughout are accurate to about one part in 10,000.

Table III.

Nominal value.	Time of charging.	Value in terms of I.	Value in terms of II.
·05	0"	·05022	—
—	5"	·05072	—
—	10"	·05080	—
·05	0"	·05055	—
—	5"	·05106	—
—	10"	·05109	—
·2	0"	·1988	·1981
—	2"	·1999	·2002
—	5"	·2007	·2009
—	10"	·2010	·2013
—	20"	·2012	—
·2	0"	·2003	—
—	2"	·2018	—
—	5"	·2027	—
—	10"	·2033	—
—	20"	·2039	—
—	30"	·2046	—
·5	0"	·5032	—
—	2"	·5058	—
—	5"	·5078	—
—	10"	·5081	—
—	20"	·5092	—

During the process of the work Mr. Bowley compared several of the resistance-boxes of the association together. As these are used as standards in many experiments, it will be useful to put the results on record.

Box Elliott 1,253 is a Wheatstone's bridge box of platinum-silver in legal ohms, said to be right at 18deg. Assuming that the two 1,000-ohm coils of the bridge are equal (and the experiments showed no appreciable difference), the following values were found for certain coils in terms of a nominal 10,000 ohms taken from 1,253.

Nominal value.	Elliott, 1,825.	Value found.
10,000		10,012
20,000		20,024
30,000		30,034
40,000		40,049

Nominal value.	Nalder, 1,870.	Value found.
100,000 No. 1		100,042
„ No. 2		100,044
„ No. 3		100,050
„ No. 4		100,034
„ No. 5		100,042
„ No. 6		100,042
„ No. 7		100,052
„ No. 8		100,032
„ No. 9		100,047
„ No. 10		100,052

The temperature of all the coils was about 15·6deg. C.

Thus the box Elliott 1,825 is right at about 4deg. below the box 1,253, while the box Nalder 1,870 is right at about 1·5deg. below 1,253.

At the conclusion of the report of the committee,

The **President** invited Prof. von Helmholtz to give the opinion held by the German authorities on the English standards.

Prof Helmholtz said they in Germany were in the same position as the English scientists. At the congress of 1884 it was determined that the French Government should bring the decision of the congress before the European Governments, asking them to legalise the standards adopted in each country. As far as he knew, the communication of the French Government had been made, but no steps had yet been taken. At the time of the 1884 congress few measurements had been made, and several delegates undertook to make new measurements, the results of which were brought before a later congress. They had then to choose between figures which had a difference of 1 per cent., and they chose the proposal of Dr. Werner Siemens, which was the mercury column, one square millimetre in section, and one metre six centimetres in length, at a temperature of freezing point. That was the most accurate number they could then arrive at. Since then the work had been continued by Englishmen, Frenchmen, and Germans, and their conclusions were more in agreement; and they could take it for granted that 106·3 was right to about [illegible]th part of the whole. This value was quite sufficient for all industrial purposes, and it would be found of sufficient accuracy for most scientific purposes. There was, therefore, no reason to remain at the former definition of the Paris congress. In April of this year they, in Germany, brought the result of their experiments before the consulting committee; about that time they received information of the English proposals, and then found it was quite sufficient to accept the proposals of the British Association Committee, which had been laid before the Board of Trade. There were only minute points on which they thought there could be any difference. The speaker's experiments, as well as those of others, showed that solid wires were very uncertain, and liable to

alteration. For higher resistances they had used German silver, and they had found that this alloy, like many others, changed its resistance. If such a wire was wound round a coil it had a larger resistance than before, and altered within some weeks; they were never sure that wires which had at first the same resistance were still the same after some months had elapsed. They had tried other alloys which had a very low temperature coefficient, and with these it was possible to get a fair degree of accuracy. It was found that an alloy principally consisting of nickel and copper had a very small temperature coefficient, and had at the same time good mechanical qualities; so that if a new coil had been wound and heated several times in boiling water, one could get it in a state in which there would be no change. Such coils when compared with mercury standards had been found to be unalterable during the space of a year. The British Association wires, which were made of platinum, silver, and several alloys, showed good constancy, except two which had been frozen, seemed to suffer some modifications in their interiors; perhaps some fissures had developed which, failing to close again, would permanently alter the resistance. While a great number of these resistances might remain unaltered, it would be different in the case of a wire coil which had been used as a standard for centuries, for anyone to look into the interior to ascertain that if there had been any alteration. They were, therefore, of opinion that it would be better to keep up the old definition of the resistance given by Dr. Werner Siemens of the mercury column. They had made many accurate experiments with the mercury column; one of his (the speaker's) assistants had found out some new errors which hitherto had not been observed. Such a mercury column placed in a narrow tube, then again placed in a thick tube of glass and surrounded by iced water, became heated to one-third of a degree which was sufficient to alter the resistance, but that alteration could be measured; it was even possible to measure the degree of conductivity of the glass tube for heat by observing that little alteration of temperature. They must suppose that all the observations of the resistance of mercury hitherto had been a little too high, and that one must take care of these alterations. A curious thing in filling these tubes was the influence of capillary force. It was demonstrated that the mercury did not completely touch the glass tube if it was not filled in a vacuum. An easier way of filling was to place a drop of petroleum between the mercury and the glass, the mercury and glass then making better contact; they got less resistance from such a column of mercury than when the ordinary methods of filling were adopted. He thought that the value of the smallest resistance was probably right for a higher resistance showed that the filling of the tube was not completed. That was a reason why the square section of the mercury column should not be defined by length, for no one could measure with absolute accuracy the internal diameter of a glass tube of a square millimetre section. It seemed better to define the square section of the mercury column by weight. As far as it was possible to make out, the English standards were in so good an agreement with the independently made standards of the Germans that there was no reason to be divided on the question. For industrial purposes, the accuracy obtained was quite sufficient, he might say, for centuries. For scientific purposes, there would perhaps be some alteration necessary, but that was a question of time. Scientific people, who had a good definition of the standards they employed, could make the little calculation necessary to reduce them to their requirements. He thought that all nations were very near an agreement. They had been sent by the German Government to try to come to an agreement with England, and he hoped that America and France would come into the same agreement with them all.

CARDIFF ELECTRIC LIGHTING.

REPORT OF THE SUB-COMMITTEE AS TO ELECTRIC LIGHTING.

In pursuance of the resolution passed by the Lighting and Electrical Committee on July 21, 1891, your sub-committee, with the exception of the chairman, Mr. Councillor Vaughan, accompanied by the town clerk, the borough engineer, and Mr. W. H. Massey, the electrical engineer appointed by the Corporation, have to report that they visited London, Deptford, Bath, Havre, Paris, Brussels, Antwerp, Cologne, and Frankfort, with the object of obtaining the latest available information as to the progress of electric lighting, and the application of electricity to general industrial purposes. The members of your sub-committee (and in this relation the term includes the officials associated therewith) have held numerous meetings in Cardiff, London, and elsewhere, at which they have had the advantage of discussing the question generally with some of the most distinguished electrical engineers and scientists engaged in the particular class of work to which the sub-committee have been desired to turn their attention. Your sub-committee have everywhere been received with the greatest courtesy, and every disposition has been manifested to put them in possession of the fullest and most trustworthy information with regard to the development of electrical science. At various points in the course of their travels upon the Continent your sub-committee have found that deputations from other important cities and boroughs in this country, and also from Glasgow and Dublin, have been engaged on similar errands of enquiry and investigation. Your sub-committee regret that they had not the opportunity of meeting and exchanging notes with any of the members of such deputations, especially as some of them were placed in a position to devote more time and money in extending the scope of their enquiries than your sub-committee felt warranted in doing. It still remains for your sub-committee before sending in their final report, to visit two or three large northern boroughs, the municipal authorities of which have already embarked in electrical enterprise, and from whose example Cardiff may learn possibly what to avoid as well as what to adopt in matters of detail.

The conclusions that your sub-committee have so far arrived at are that the promise of advantage to the community at large to be derived from the development and application of electricity in the future, is such that a prudent municipality will not allow the control of what must practically be a monopoly to pass into the hands of any private individual or company, established for the purpose of profit. This is altogether apart from the still graver consideration of allowing any other body than the Corporation to come into the borough armed with parliamentary powers to tear up the streets and pavements of the Corporation. In order to secure the control of the supply of electricity in the borough it is incumbent on the Corporation, within two years of the granting of the provisional order (3rd July, 1891), to put down works, and be prepared to supply electric current over a certain compulsory area, which may roughly be defined as embracing the portions lying between Westgate-street to the west, Working-street and the Hayes to the east, Castle-street and Queen-street to the north, and Custom House-street to the south. It has been estimated that mains can be laid and works established within the area itself at a cost of about £30,000. Your sub-committee are, however, of opinion that whatever works are laid down should be designed not only to supply the electric current in the compulsory area, but also to form the nucleus of a supply station, capable of producing the whole of the electric current likely to be required throughout the borough during the term of the provisional order, viz., 42 years. In selecting a site for permanent works it is of the highest importance that there should be proper communication by siding with a line of railway, for the sake of obtaining cheap coal (in respect of which Cardiff has immense advantages over London and other places), and also access to an unlimited supply of fresh water for condensing and other purposes. Such a site the sub-committee believe could be obtained in the neighbourhood of the Dumballs, adjoining the timber pond. This site is sufficiently near the compulsory area to enable the lighting of that area to be carried on at very little more cost than has already been estimated, and what is perhaps of equal importance, by means of electrical currents of only moderate pressure.

The members of the Corporation are doubtless aware of the difference between incandescent and arc lighting. The one—incandescent or glow lamp—is generally utilised for domestic purposes, and the other—the arc light—for street lighting and illumination of large areas, such as railway stations, manufactories, and workshops. A different electrical pressure is generally used for each of these methods of lighting, what is called the low-tension current being employed for domestic purposes, and high tension for arc lighting, or for primary transmission. Without going into any technical details, it may be broadly stated that for economical reasons high-tension currents are necessary when it is required to distribute electricity to long distances or over large areas. It has already been demonstrated that this high-tension current can be transformed into low tension and thus made available for incandescent lighting by a very simple appliance, and your sub-committee are hopeful, from what they saw at Frankfort, and from what they gathered in conversation with electrical engineers abroad, that this transformation can be accomplished in an economical manner. In that case it is obvious that the most practical method of lighting a scattered district like the borough of Cardiff would be by concentrating the machinery in one spot, and distributing the electrical energy at a sufficiently high pressure over the given area, such current to be transformed as and where required. The objection to high-tension currents consists principally in the danger to life and property which unprotected cables having such currents are likely to cause. By a proper system of insulation, and laying the cables underground, however, this can be entirely obviated, but the higher the tension the greater is the cost of insulating and providing safety appliances, and that is one reason why your sub-committee call special attention to the moderate pressure likely to be required for distribution in Cardiff.

Assuming that the Corporation decide to undertake the supply of electricity throughout the borough of Cardiff, and to establish one principal station, the matters they would have to take into consideration in relation thereto would divide themselves into three main branches: 1. Street lighting. 2. Domestic lighting and shops. 3. Supply of power.

Street Lighting.—The best examples of street lighting that your sub-committee have inspected have consisted of a combination of arc lighting and gas, such as is seen at Brussels and Paris. Your sub-committee are of opinion that a somewhat similar arrangement would solve the difficulty with regard to lighting the main streets of Cardiff, and that by this method such streets within the compulsory area could, at a reasonable cost, be lighted as brilliantly as the streets of any city or capital in Europe. Your sub-committee would, however, suggest that in order to accomplish this end it would be necessary that the electric lamps should only be run from dusk to midnight, at which hour they should be extinguished and the ordinary gas lamps lighted. Appended to the report is a statement by the borough engineer, showing exactly what the cost of lighting the streets of the compulsory area by gas is at the present moment, and what he estimates it would be in the manner suggested by the sub-committee. At Bath the arc lamps are so far apart that the effect which otherwise might be produced is seriously impaired, and such a method of street illumi-

mation would not commend itself to the ratepayers of the town of Cardiff. In Bath, even with what your sub-committee consider insufficient lighting by electricity, the cost to the local authorities has been increased by £1,600 per annum over what was formerly paid for gas. The best example of electric street-lighting that your sub-committee have seen in England is that carried out by the Brush Company, in Queen Victoria-street, London, where the arc lamps are placed at an average distance of nearly 45 yards apart. The yearly cost of each lamp is £26, and the charge for lighting this street is therefore at the rate of about £1,000 per mile per annum. In this case, as at Bath, the lamps are run from dusk to dawn.

Domestic Lighting and Shops.—As the result of very full enquiries it appears at present that effective domestic lighting by incandescent lamps costs two-and-a-half times as much as gas lighting—light for light, and hour for hour, and in some places the cost is even greater than this. Yet, notwithstanding, your sub-committee found that everywhere incandescent lighting was in great and increasing demand; and there are cogent reasons for this demand, for experience shows that in private houses electricity is not only a light of luxury, but a light of health. As regards public buildings and business premises filled with expensive goods, economy is indirectly effected through the absolute freedom from noxious vapours and other destructive products of combustion; therefore, by the use of electric lighting in lieu of gas, the shopkeeper saves his goods, and the community its treasures and artistic decorations; and as against the extra proportionate cost of electric light is to be set the economy which can be effected by the much greater ease with which the light is turned on and off, so that the lamps themselves are not kept continuously burning, as in the case of gas. In private dwellings this is of the greatest importance. For instance, when persons move from room to room they instinctively operate the switches conveniently fixed near the doorways, and so use the lights only when, as, and where they are actually required. In the same way in a bedroom lights need not be kept burning all night, because the room can be instantly illuminated by turning on a switch near the bed, and thus the consumption of electric current only occurs when absolutely necessary. In London some of the companies are being worked at a profit, whose business consists almost entirely of the supply of low-tension current for incandescent lighting. But it will be scarcely necessary for your sub-committee to say that the stations of these companies are situated in the heart of the wealthiest districts, where great mansions, clubs, and hotels are concentrated, and where the demand for electric lighting is, perhaps, 10 times as much as it would be over an equal area in Cardiff. As an illustration, your sub-committee need only mention that some of the clubs in Pall Mall and neighbourhood spend over £1,000 a year upon the electric light.

Supply of Power.—At Frankfort your sub-committee witnessed a most interesting example of the ease and economy with which motive power can be transmitted over long distances. At Lauffen, about 110 miles away, a waterfall operated dynamos from 100 h.p. to 300 h.p. The energy was transmitted through bare overhead wires carried on insulators to the electrical exhibition at Frankfort, where it was used for lighting, and also for driving motors for working pumps and other machinery. Your sub-committee were informed that the loss in transmission over this enormous distance was less that 10 per cent. They also saw numerous electric motors varying in power from tiny instruments suitable for operating drills used by dental surgeons up to motors for working large printing machines, and heavy tools used for industrial enterprises, and other works requiring considerable power. The result of your sub-committee's enquiries satisfied them that the electrical motors are being extensively used, both on the Continent and in the United States of America, and that a considerable revenue is likely to be earned in the future by central stations supplying electricity for both light and power.

Your sub-committee also witnessed a most efficient, simple, and economical method of working tramways by electricity. In this instance, the wires were carried overhead upon very simple and not inelegant supports, which, as far as your sub-committee could judge, would, if raised a little higher, afford no obstruction to traffic on country roads, and it is probable that, in some of the suburbs of Cardiff, a similar arrangement might with advantage be introduced, as is the case in Leeds, where just outside the town an electrical tramway, worked by overhead wires, is on the point of being opened with the sanction of the Board of Trade, at the request of the local authorities; but there are numerous reasons why no system of overhead wires, however economical and efficient, would be tolerated in the streets of a large town like Cardiff, and consequently some method of underground distribution will have to be devised. Your sub-committee have inspected the various systems in operation in London and on the Continent, but having regard to local conditions and to the special requirements of Cardiff, they have not yet seen anything which they could recommend the Corporation to adopt without modification. The borough engineer and Mr. Massey are going very thoroughly into this matter, and your sub-committee feel sure that something worthy of acceptance will be designed. The same remarks apply to more simple questions with regard to the precise kind of machinery and appliances to be adopted, and other details of the constructional portion of the works which they consider it would be best to adopt; but they hope to deal with these matters fully very soon after they have completed their enquiries.

Dated the 30th October, 1891. Signed by P. W. Carey, chairman of sub-committee; Lascelles Carr; J. L. Wheatley, town clerk; W. Harpur, borough engineer; Wm. H. Massey, electrical engineer appointed by the Corporation.

ELECTRIC LIGHTING.

Statement by borough engineer of present cost of lighting compulsory area by gas, and estimated cost of lighting same area, partly by electric lighting and partly by gas, as recommended by report of sub-committee, dated October 30, 1891. The streets comprised in the compulsory area are at present lighted by means of the following lamps—viz.:

3—130-c.p. lamps at	£12	10	0	...	£37	10	0
1—150 ditto at	13	5	0	...	13	5	0
70—100 ditto at	6	17	6	...	481	5	0
1—100 ditto at	7	10	0	...	7	10	0
5—50 ditto at	6	0	0	...	30	0	0
29—16 ditto ordinary street lamps at	2	16	0	..	81	4	0
Total cost per annum					£650	14	0

To light the same streets partly by electricity and partly by gas, in the manner recommended by the sub-committee, the borough engineer estimates the cost would be as follows—viz.:

60 electric arc lamps, burning from sunset to midnight at	£12	0	0	...	£720	0	0
82 ordinary street lamps burning from midnight to dawn at present rate of prices, at	1	18	3	..	136	16	6
12 ordinary lamps burning from sunset to dawn, as at present, at	2	16	0	...	33	12	0
2 100-c.p. lamps burning as at present, at	6	17	6	...	13	15	0
1 150-c.p. lamp burning as at present	—			...	12	10	0
2 50 c.p. lamps burning as at present, at	6	0	0	...	12	0	0
Estimated cost per annum					£948	13	6

24th November, 1891. W. Harpur, Borough Engineer.

FURTHER REPORT OF THE SUB-COMMITTEE.

To the Lighting and Electrical Committee,—In accordance with the instructions contained in the resolution passed by the Lighting and Electrical Committee on December 15, 1891, by which resolution Mr. Alderman Carey, Mr. Alderman Jacobs, Mr. Councillor Trounce, the town clerk, the borough engineer, and Mr. W. H. Massey, were authorised to institute full and comprehensive enquiries into matters which had previously been brought to the notice of the Corporation in an interim report dated October 30, 1891, your sub-committee now beg to report that they have specially visited Leeds, Bradford, and Manchester, and that on more than one occasion when in London they have, either in company with the mayor and other members of the Corporation, or as a committee alone, visited also most of the largest and newest electric lighting centres in the metropolis, in order to arrive at a proper decision of the important questions referred to them. They have been to the Electrical Exhibition at the Crystal Palace, where they were much impressed with the numerous applications of electricity for the transmission of power, and here, as well as elsewhere, they had good opportunities of meeting engineers of high standing, with whom your sub-committee discussed many matters which must be taken into consideration when dealing with a business affecting, as this does in many ways, the interests of ratepayers in a rapidly-growing town like Cardiff.

The result of your sub-committee's investigations is to confirm generally the opinions expressed in the preliminary report before referred to, but to make the present report more complete in itself, your sub-committee think it well to state their views somewhat fully, at the risk of repetition, and of thus dealing with questions upon which the members of the Corporation are already well informed.

The remarkable extension of electric lighting in every direction is neither sudden nor transient, but it is the natural development of an industry now permanently established in this country. There are towns in which it appears to your sub-committee unlikely that the electric light can be carried on at a profit; but having regard to the special advantages which Cardiff undoubtedly possesses over many other places, because of its cheap fuel and abundance of water for condensing purposes, the powers obtained under the provisional order are certain to prove of value, and your sub-committee strongly urge upon the Corporation the desirability of itself retaining these powers, as well as the control over the streets and pavements.

By the terms of the Cardiff provisional order, the Corporation should, within two years from July 3, 1891, be placed in a position to supply current to the inhabitants of that portion of the town included in what is styled the "compulsory area," a district of a somewhat irregular shape, situated between the Great Western Railway Station, the Taff Vale Station, and Cardiff Castle, as outside points; and for the lighting of that district alone it would be possible to erect a small central station within the area itself; but your sub-committee feel sure that it would be more economical in the end, besides being fairer to the community at large, to put the electric lighting station on some convenient site outside the compulsory area, and in such a position as to be available for the lighting of other portions of the town as well. In laying down the requisite plant in the first instance it is quite easy to so arrange it that by making additions to the building and the machinery the whole may be gradually formed into a generating station suitable for the supply of electrical currents for both light and power throughout the entire borough; and by this means establishment charges, and expenses for staff and maintenance, would be reduced to a minimum.

It would be almost impossible to mention all the subjects to

which your sub committee have devoted so much of their time and attention, but allusion should be made to some of them. The utilisation of water power in connection with the new Taff Vawr mains, and the adaptation of refuse destructors, by passing the waste heat and gases through boiler furnaces for the purpose of raising steam to drive electric light machinery, are schemes which may all be realised to some extent in the not distant future, and yet they do not in any way modify the present needs. It is probable that electricity will play an important part in the propulsion of tramcars—an example of which was seen at Leeds, where a somewhat unsightly overhead wire conveys the current—and that suitable conduits might be combined with an underground system of electric light distribution, but in the existing state of affairs the latter must be looked upon as distinct in itself and be dealt with accordingly.

The vexed question of high versus low tension has frequently and in many forms been brought before your sub-committee, and it is clear that in order to make a commercial success of an electrical undertaking, regard must be paid to local conditions. It would be a suicidal policy to introduce into a sparsely populated town a low tension system such as may have proved successful in every respect in the heart of a densely packed city. The other extreme is to be avoided, of course, and it is satisfactory to know that for the lighting of the borough of Cardiff currents of only a moderately high pressure will be sufficient for the distribution of the electricity to all parts of the borough, and that the buildings and dwellings can be supplied with low tension currents.

Compared with the price of ordinary gas lighting, the cost of effectively lighting streets by electricity is decidedly greater if current has to be obtained from a supply company, but the Corporation would, as producers of their own current, be in a position to economically light the principal thoroughfares of the town by means of arc lamps or more probably by arc lamps and gas, after the manner indicated in the report which has already been referred to, while others of the main streets might be lighted by glow lamps of high candle power. But for many streets gas will for a long time prove to be the cheapest and most convenient illuminant.

In reference to private lighting, your sub-committee found, in many instances, that notwithstanding the increased cost of the electric light as compared with gas, consumers preferred the adoption of electric lighting, and they would on no account return to gas. The amount saved in stock, decorations, etc., formed an important item in this estimate.

Your sub-committee have not the means of forming a very exact estimate of the total cost of establishing the electric lighting station, and of laying the mains throughout the compulsory area; but, from figures submitted to them, and judging by what has been done elsewhere, they think that a sum of between £25,000 and £30,000 will be sufficient to begin with, to thoroughly equip the station, and to supply the district in conformity with the conditions imposed by Parliament, the cost depending, however, to some extent on the site chosen and on the price paid for it, or whether it be leased instead of being purchased.

Having regard to the fact that it will take about one year to get everything into working order, it would be unwise to postpone the consideration of the subject, and your sub-committee would, in conclusion, recommend that as soon as a site for the station can be obtained, the borough engineer and Mr Massey be instructed to prepare immediately plans and specifications upon which estimates may be obtained from builders, electrical contractors, and engineers for the whole of the plant necessary to enable the Corporation to carry out electric lighting works in accordance with the requirements of the provisional order.

Dated this 3rd day of May, 1892. Signed by P. W. Carey, chairman of sub-committee; T. Windsor Jacobs; W. J. Trounce; J. L. Wheatley, town clerk; W. Harpur, borough engineer; W. H. Massey, electrical engineer.

THIRD REPORT.

The proceedings of the sub-committees held on July 19 and 22, and August 2, were read, and also the following additional report of the sub-committee: Pending the fuller consideration of the interim report dated May 3, 1892, which was printed and circulated among the members of the Lighting Committee, a special committee consisting of the mayor (Mr Alderman Reed), and the chairman (Mr Councillor Vaughan), with the borough engineer, have entered into negotiations for obtaining a suitable site for electric light works in those localities which appeared to be the most convenient; but as the prices asked were prohibitive in some cases, while in others there seemed little prospect of the offers made on behalf of the Corporation being accepted without very serious delays taking place, your sub-committee were obliged to search for a somewhat less desirable place in other directions, and they beg to report that, failing to find a more favourable situation, some portion of the Corporation's own property at Canton can be made available if, as they believe, the supply of fresh water proves sufficient for the purpose in view. A trial hole is being sunk, and there would seem to be no doubt that water in very large quantity is to be had quite close to the surface. The subsoil is gravel, so that there will be no trouble with the foundations of buildings, etc., and as the plot of land adjoins existing railway sidings the facilities for getting coal are great. The only modification requisite in the scheme proposed by your sub-committee in their previous reports will be in regard to the pressure necessary for transmitting the electric current. The distance from which the supply is to be brought being greater, the cost of mains will, of course, be somewhat increased; but the efficiency of the system can be maintained by slightly raising the E.M.F. at the generating station, and the distinct saving in the amount allowed for the site will more than cover the extra sum which would have to be expended in the longer mains. Having inspected the works of the Bournemouth Electric Light Company, which are more than two miles out of that town, your sub-committee (consisting of the chairman, Mr. Alderman Jacobs, and Mr Councillor Trounce, with the borough engineer, and Mr. Massey) are confident that no real difficulty will arise in dealing on similar lines with the larger supply that will be needed for Cardiff; and the chairman, who has since his return from the Antipodes gone very thoroughly into the whole matter in London and other towns, finds himself in complete accord with the conclusions arrived at after so much care and thought by the other members of your sub-committee. As soon as the question of sites has been disposed of, plans can be prepared and estimates obtained; and your sub-committee would suggest that the work be now pushed on as quickly as possible.

Signed by Wm. M. E. Vaughan, chairman; Thomas Rees, mayor; T. Windsor Jacobs; P. W. Carey; W. J. Trounce; W. Harpur, borough engineer; W. H. Massey, electrical engineer.

LEGAL INTELLIGENCE.

ESK v. THE PLANET ELECTRIC LIGHTING COMPANY.

This case was one of considerable importance to electrical engineers, and was heard before his Honour Judge Bayley at the Westminster County Court on Friday last. The plaintiff is a traveller in electrical appliances, and he sued the defendant company to recover a month's wages in lieu of notice.

The facts of the case were that in July the plaintiff called at the offices of the defendant company in reference to obtaining orders for the installation of their electric light. In the first instance he saw Mr. Slatter, who was the manager to the company, and after a conversation on the subject he was told that, subject to his reference being satisfactory, he would be engaged for a month on trial to represent the defendant company out of doors. That took place on a Thursday, and it was arranged that the plaintiff should commence work on the following Monday morning if his reference was approved of. The reference was received in due course and on the Monday morning the plaintiff commenced operations. On the following day (Tuesday) the plaintiff called at the office of the defendant company, when he saw Mr Charles Scott, who was the secretary, and informed him that he was making some progress in the work, and had that day to go to Islington to see Major Probyn in reference to the installation of electric light at Bisley Camp. At the same interview he asked the secretary to give him some money on account of travelling expenses, but he refused to do so on the ground that the engagement had not yet been ratified by the company. Some rather unpleasant conversation then ensued, and it ultimately resulted in the refusal on the part of the secretary to pay anything, and he further expressed his regret at ever having made an arrangement which the directors would not ratify.

For the defence **Mr Charles Scott** was called, and said he had an interview with the plaintiff on the day after he commenced work, and he then asked him for some money on account of travelling expenses. Witness told him that the engagement had never been ratified by the directors, and, therefore, he had no power to pay him anything on account of expenses.

The **Plaintiff** then asked for the return of his reference, but witness refused to give it up on the ground that the document was a confidential one.

His **Honour** said he was of opinion that the plaintiff never was actually engaged, and, therefore, he was not entitled to make any claim. Judgment would be for defendants with costs.

COMPANIES' MEETINGS.

CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Wednesday at the offices, Old Broad-street, Mr. Thomas Greenwood presiding.

The **Chairman** said their income had been about £1,100 more than that of the corresponding period of the previous year, but this was due to the fact that during a part of the half year ended June, 1891, with which they were now comparing, their lines were interrupted. The expenditure for the past half year had been about £80 less, although they had made rather an unusual charge for depreciation on stores and cable in stock, namely, £[illegible] for the half year. To fill the vacancy at the Board caused by the death of Mr Neal Bannatyne, Mr George Keith had been appointed. That gentleman had been their engineer and general superintendent in Cuba for over 15 years, and as he desired to remain in England he had been elected a director. In that capacity he would receive £200 a year, and in addition he would have £400 a year for taking the entire supervision of the cables, and the responsibility of looking after them with the assistance of one of the Company's servants in Cuba. In the event of the cables requiring repair Mr. Keith had undertaken to do the work, and he would receive, during the time he was away from England, the salary he would have received as general manager in Cuba. Altogether, by these arrangements, a considerable saving had been effected. He concluded by moving the adoption of the report.

Mr. Charles W. Parish seconded the motion.

In reply to a shareholder, the **Chairman** stated that the

Directors could give no further information than was contained in the report respecting the Company's suit against the Spanish Government. They were not damaged by the delay, and they did not press the matter.

The motion was adopted.

PIONEER TELEPHONE COMPANY.

An extraordinary general meeting of this Company was held at Winchester House, the Duke of Marlborough presiding, to consider a resolution for winding up the Company.

In proposing the motion the **Chairman** stated that the Company was formed originally to inaugurate a new departure in a new and important industry, and those who had supported it had been enabled to secure a reasonable profit on the risk they had undertaken. The Company had done some useful work, and it obtained certain important contracts with the view to the eventual establishment of an extensive telephone system throughout the country. They acquired the Mutual Telephone Company at Manchester, and thus constituted themselves, with their other acquisitions, a going concern. The interest in their Manchester undertaking had been purchased by the New Telephone Company, which had been formed out of the Pioneer Company, and thus the objects of the original company had been accomplished. There was no doubt that the New Telephone Company would be of great advantage both to the metropolis and the country generally; and by the arrangement which had been come to with the National Company a working alliance had been established under which there would be no waste of capital through rival systems, and there would be plenty of room for both companies. The public, too, would be greatly benefited.

The motion was adopted.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The half-yearly meeting of this Company was held in Liverpool, Sir William B. Forwood in the chair.

Questions were asked about the recent issue of debentures, several shareholders complaining that they had not had the opportunity of subscribing for them. The **Chairman** explained that ample notice was given that the debentures were to be issued. No application was received from a single shareholder, and the Directors felt that if they had offered the bonds to them they might have been left with some for which they could find no customers. The bonds were taken by the Bank of Liverpool, and the Company had paid the bank 1½ per cent. to cover brokerage and all costs of issue.

The report was adopted.

COMPANIES' REPORTS.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

Directors: Joseph Ebbsmith, Esq., chairman; M. J. Smith, Esq.; William Neale, Esq.; W. J. Carruthers-Wain, Esq., A.M.I.C.E., managing director.

Report of the Directors to be submitted to the shareholders at the eleventh ordinary general meeting, to be held at The Queen's Hotel, Stephenson-place, Birmingham, on August 24, 1892, at 12.30 in the afternoon.

The subjoined statement of traffic and profit shows that the profits of the steam department have been materially reduced by the charge for fuel (part of which is exceptional, and by the repairs to engines. The electric department shows a loss chiefly due to the heavy charges for renewal of batteries, but your Directors have now under consideration a contract for maintenance of batteries, which it is hoped will tend to material economy and profit of working. The cable department has again shown a gratifying result, and it is evident that upon routes of heavy traffic and severe gradients no other system of traction at present in operation can compete with the steel rope. The particular attention of the shareholders is directed to the diminution of profit consequent upon the constant increase of the charges for maintenance which, under the terms of the leases of the lines within the city as settled by our predecessors, we are bound to pay. How serious these are will appear from the following statement of the amounts paid in successive years: 1885-6, £249. 2s. 6d.; 1886-7, £654. 8s. 7d.; 1887-8, £739. 19s. 6d.; 1888-9, £1,935. 15s. 4d.; 1889-90, £4,683. 0s. 10d; 1890-91, £5,058. 1s. 3d.; 1891-92, £6,593. 3s. 2d. It is quite clear that so large and increasing an expenditure can only be met by an increased revenue. After careful deliberation your Directors are of opinion that this increase of revenue can be earned by the conversion of the Stratford-road line into a cable line, which would be a source of great profit to the Company and great convenience to the travelling public, and would increase the security of the Corporation. They have, therefore, with the concurrence of some of the largest shareholders, applied to the Public Works Committee of the Corporation to allow the expenditure of the whole, or part at least, of the sum of £68,580 (which the Corporation hold as security, and on the bulk of which they allow interest at the rate of 3½ per cent. only) to be applied for that purpose, and they recommend that the committee of the representatives of the shareholders may have authority given to them by the general meeting to assist your Directors in this matter. The revenue account shows a balance of £17,659. 4s. 11d., to which has to be added the sum of £1,262. 3s. 9d. brought forward from last year's accounts, making together £18,921. 18s. 8d. Your Directors recommend — 1. That the payment of the dividend upon the 5 per cent. guaranteed shares, amounting to £5,000, be confirmed. 2. That the balance of revenue account, amounting to £13,921. 18s. 8d., be carried forward pending the result of the application to the Corporation of Birmingham above referred to, and also pending the decision of the shareholders as to any reduction of the nominal amount of the ordinary capital. It has been represented to the Directors by many large shareholders, that the time has arrived for reduction of the ordinary share capital from £10 to £5 per share. Diverse views appear, however to be held upon the subject, and your Directors consider that the authority of the committee of shareholders might, with propriety, be extended to the consideration of this matter also. Mr. M. J. Smith and Mr. W. Neale (two of the Directors) retire, and, being eligible, offer themselves for re-election. Messrs. Howard Smith, Slocombe, and Co. offer themselves for re-election as auditors of the Company.

[The report also contains working accounts for 12 months of the various forms of traction used. The steam traction shows that the average cost per mile run was 15·96d. In the horse department it was 11·20d.; in the cable department it was 12·20d.; in the electric department—full details of which we give—it will be seen to be 15·39d. It is unnecessary for us to do more than give details of the electric working, which unfortunately resulted in a loss.]

NEW COMPANIES REGISTERED.

United Electric Sewage and Chemical Syndicate, Limited.—Registered by E. M. Walker, 132, Adelaide-road, N.W., with a capital of £5,000 in £1 shares. Object: to acquire certain patents relating to an improved process for the purification of sewage, and to develop and turn to account the same. Registered without special articles.

Hove Electric Lighting Company, Limited.—Registered by Deacon, Gibson, and Medcalf, 4, St. Mary-axe, E.C., with a capital of £40,000 in £5 shares. Object: to carry into effect two agreements expressed to be made between this Company of the one part and the Hove Commissioners and Messrs. Crompton and Co., Limited, of the second parts respectively, and to carry on the business of an electric lighting company in all its branches. There shall not be less than three nor more than five directors; the first are to be elected by the signatories to the memorandum of association. Qualification, £500. Remuneration: Chairman, £150 [illegible]

annum; ordinary directors, £200 per annum, divisible, with a further sum of 5 per cent. of the remaining profits after payment of 7 per cent. dividend.

Cambridge Electrical Engineering Company. —This Company has been formed for the purpose of carrying on the business of electrical engineers and contractors. The board of directors is composed of the following gentlemen: Mr. H. Eaden, Market-hill, Cambridge; Mr. C. A. M. Fennell, Litt. D., late Fellow of Jesus College; Mr. James D. Pryor, Furness Lodge, Cambridge; Mr. A. Barrett (electrical engineer), managing director; and Mr. B. M. Baily (who will join the Board after allotment and receive no remuneration as director for the first two years), who have power to add to their number. The Directors have acquired the business of electrical engineers hitherto owned and carried on by Messrs. Baily and Grandy, of St. Mary's passage, Cambridge, together with their rights and interests in certain patents connected therewith, and their existing contracts for illumination.

Collier-Marr Telephone and Electrical Manufacturing Company, Limited. —Registered by Nicholson, Graham, and Graham, 24, Coleman-street, E.C., with a capital of £100,000 in £10 shares. Object: to acquire as a going concern the business of the Collier Audible Telephone Syndicate, Limited, and with a view to the acquisition thereof to adopt and carry into effect an agreement, made March 17, between the Collier Audible Telephone Syndicate, Limited, of the one part, and E. Hampton, on behalf of this Company, of the other part, such agreement, however, being modified by an agreement expressed to be made between the same parties, and bearing date August 5, 1892; generally, to carry on business as manufacturers of and dealers in telephones, cables, wires, lines, accumulators, engines, etc., or any other apparatus or things connected with the establishment, working, and maintenance of telephone communication, or in connection with the generation, distribution, supply, accumulation, or employment of electricity. The first subscribers are:

	Shares.
H. Matthews, Darby-street, Manchester	1
H. J. Owen, 14, St. Mary's gate, Manchester	1
J. E. Pilling, 27, Leaf-street, Hulme, Manchester	1
G. Graham, 194, St. Clements road, Chorlton cum Hardy	1
W. Spencer, 322, Manchester-road, Hollinwood	1
T. Chapman, 311, Bolton-road, Pendlebury	1
W. Frost, Spring Bank, Irlams o'th Height, Manchester	1

There shall not be less than five nor more than seven Directors. The first are J. W. Maclure, M.P., G. C. Thompson, J.P., H. S. Foster, M.P., H. F. Herford, A. T. Collier, and A. Marr. Qualification, £200. Remuneration, £1,000 per annum, divisible amongst them as they themselves shall determine.

BUSINESS NOTES.

West India and Panama Telegraph Company. —The receipts for the half month ended August 15 were £1,882, against £1,630.

City and South London Railway Company. —The receipts for the week ending Aug. 14th were £721, against £653 for the same period of last year, or an increase of £68.

Change of Address. —MacLean's Telegraphic News Exchange has been removed from St. Stephen's chambers, Telegraph street, E.C., to 32, Cockspur street, Charing Cross.

Western and Brazilian Telegraph Company. —The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,818.

Westminster Electric Supply Corporation, Limited. —The Board have declared an interim dividend for the half year ending June 30 last at the rate of £3 per cent. per annum. This dividend will be payable on September 15 next to all shareholders whose names are on the register on August 10, and the warrants will be issued in due course.

City Lighting. —The tender of Messrs. Pearson and Co., Fenchurch street, London, for the supply and erection of the constructional ironwork for the Meredith's Wharf Depot of the City of London Electric Lighting Company, Limited, has been accepted, the amount being £2,396. The plans and specifications were drawn up by Major General Webber, C.B., and Colonel Seddon, engineers to the Company.

PROVISIONAL PATENTS, 1892.

AUGUST 8.

14296. **Improvements in arc lamps.** Ben Death, 27, Martin's-lane, Cannon street, London.

14309. **Improvements in electricity meters.** Francis Teague, Ernest Francis Moy, and John Abbott Iliffe.

AUGUST 9.

14360. **An electric bell.** George Davis, 46, Brookbank road, Lewisham, London.

14363. **Improvements in the method of and apparatus for transmitting and receiving time signals over main and local electric circuits.** William Franklin Gardner, 28, Southampton buildings, Chancery-lane, London. *(Complete specification.)*

14395. **Improvements relating to electric furnaces for the treatment of auriferous sulphide ores and for other purposes.** John Walter Cann and Robert Edden Cannans, 433, Strand, London.

14410. **Improvements in combined fishing and life boats to be propelled by hydraulic mechanism actuated by steam, electric, or other known power.** Joseph Fletcher Green, Blackwall yard, London.

AUGUST 10.

14423. **Improvements in electricity meters.** Arthur Wright, 26, Park crescent, Brighton.

AUGUST 11.

14481. **Improvements in decorating chandeliers, gasaliers, lamps, and electric light fittings.** Harry Hateley, 128, Colmore row, Birmingham.

14489. **Improvement in governing devices for electromotors.** Thomas Cattrus, Elmwood Electrical Works, Camp road, Leeds.

14512. **An electric combination street alarm-box for fire, police, and other purposes.** Henry Binko, 34, Leadenhall street, London.

14533. **An apparatus for converting alternating currents of electricity into direct currents.** Richard Norman Lucas and Anthony George New, 12, Palace chambers, 9, Bridge-street, Westminster, London.

AUGUST 12.

14558. **Improvements in lampholders for incandescent electric lamps.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Electrical Works, Salford, Lancashire. (Complete specification.)

14567. **Improvements in grooved wood cases for electric cables or wires.** Samuel Hindley, 126, Landsdowne road, Sheffield.

AUGUST 13.

14647. **Apparatus for controlling the electric current on putting electromotors in circuit.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

14658. **Improvements relating to electric accumulators or secondary batteries and to the manufacture of plates or electrodes therefor.** Arthur James Smith, 11, Southampton buildings, Chancery lane, London.

14659. **Improvements in and relating to electric accumulators.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Frederick Clarence Jenkins, Germany.)

14660. **Improvements in and relating to the manufacture of plates for electric accumulators.** Jules Rousseau, 45, Southampton buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1888.

19043. **Insulating telegraph wires, etc.** Fowler. (Second edition.)

1891.

4838. **Incandescent electric lamps.** Bailey and Warner. (Second edition.)

12992. **Measuring electric currents.** Aron.

12831. **Curative electric belts, etc.** Russell.

13961. **Electrical parcel exchange system.** Bennett.

14217. **Telegraphic apparatus.** Sacco and Giacomini.

14817. **Electric tramcars.** Heys. (Brown.)

15768. **Distributing electricity.** Hall.

16091. **Electric circuits for lighting, etc.** Massey.

16113. **Suspenders for electric lamps.** T. H. and C. O'Brien.

17100. **Electric accumulators.** Lake. (Société Electrometallurgique Montechappi, Système de Khotinsky.)

1892.

1497. **Couplings for electric wires.** Shiels.

11403. **Electric generators and motors.** Goolden and Atkinson.

11424. **Telephone, etc., exchanges.** Dymond. (Strowger.)

11692. **Electric locomotives.** Pardon and others.

11698. **Insulators for electric wires.** Meyer.

NOTES.

Bombay.—The managers of the Petit Mills are introducing electricity as motive power in lieu of steam.

Church Lighting.—It has been arranged to light Free St. Paul's Church, Glasgow, by electricity, at a cost of about £200.

Italian Telegraphs.—A report recently issued shows a great development in the Italian telegraphic service during 1890.

Berlin Tramcars. — Electric light having proved satisfactory on the Berlin omnibuses, it will be adopted on all lines, including the tramcars.

A Large Contract.—The contract for 17 miles of electric railroad for 300,000dol. at Cuyadetta, U.S., has been given to Mr. H. Ward Leonard after severe competition.

Niagara.—Two turbines of 5,000 h.p. have been ordered, we understand, for the Niagara transmission plant from Messrs. Foesch and Piccard, water power engineers, of Geneva.

Munich.—The municipal authorities of Munich have sanctioned the lighting by electricity, to the extent of not more than 300 h.p., of the public streets of their ancient city.

American Brush.—The Thomson-Houston Electric Company own a controlling influence in the American Brush Electric Company, for which they paid two and a half million dollars.

A Warning.—An electrical engineer's apprentice named M'Connell was stabbed in Belfast on Thursday last week for refusing to stop singing "Ta-ra-ra-boom-de-ay." His condition is precarious.

Madras Telegraphs.—A through telegraph wire from Calcutta to Madras is about to be erected. The length of the new line will be 1,900 miles. Copper of a special thickness will be used.

Electric Launches.—The concession for use of electric launches at the Chicago Exhibition has been let provisionally to the Columbia Electric Launch Company, but it is probable other companies will also have launches running.

Coventry.—The Council, upon the proposal of Alderman Hill, have instructed the Electric Lighting Committee to take into consideration letters which have been received, and recommend to the Council a scheme for electric lighting.

Scottish Telephones. — The National Telephone Company have reissued their directory of the subscribers for the South of Scotland, which has grown so much as to necessitate its being reset in smaller type to keep it into a handy size.

Kinsale.—The Kinsale Town Commissioners will, at the next meeting, September 5, receive and consider tenders for the lighting of the town during the next 12 months. Application to be made to Mr. M. Hegarty, clerk to the Commissioners, Kinsale, Ireland.

Wolverhampton.—The Wolverhampton Town Council have approved of the Lighting Committee's report relative to the supply of electricity within the borough, and the appointment of a special committee to advertise for tenders for the construction of the necessary works.

Thunderstorm on the Continent.—During a violent storm on Monday at Vienna the buildings of the International Musical and Dramatic Exhibition, in the Prater, were struck five times by the lightning. Fortunately no one was injured, and only slight damage was caused.

Lightning at Osborne.—During a storm on the evening of Thursday last week a hayrick on Barton Farm, Osborne, Isle of Wight, the property of the Queen, was struck by lightning and totally destroyed, despite the efforts of the staff who had charge of the fire engine kept at Osborne.

Thunder at Bristol.—During the recent thunderstorm at Bristol, a remarkable and prolonged clap of thunder startled thousands of people. Quite a panic occurred in the centre of the city, many thinking that the earthquake of last week was about to be repeated in more violent form.

Glasgow.—The mains are now being laid in Glasgow with a view to the lighting of the central part of the town before the winter. They are designed on the principle, familiar in Westminster and St. Pancras, of bare copper bands 1in. broad by ⅛in. thick laid on earthenware insulators in iron troughing.

Wire-Table. — Messrs. W. T. Glover and Co. have issued a table showing relative dimensions, lengths, and resistances of pure copper wire, both standard and Birmingham wire gauge. The table is beautifully printed, mounted, and varnished, and should be hung in the office of every electrical engineer.

Mont Blanc.—A stout wooden observatory has been constructed for the summit of Mont Blanc, and is packed off to Chamounix. The attempt will be made to erect it during this summer. It is 25ft. high, in two storeys, with several rooms in each. Communication will at present be made by semaphore to Chamounix.

Edison Works.—Edison seems to have been unfortunate lately. Not long ago a department of the Schenectady Works was burned to the ground, and now soon after the new works recently erected by Edison at Ogden, New Jersey, for the treatment of iron ore magnetically, collapsed suddenly and four persons were killed.

Boston Edison Station.—A very complete description of the station of the Edison Company at Boston, U.S., by Mr. A. C. Shaw, is given in the New York *Electrical Engineer* for August 10. Great credit is to be given to Mr. Shaw for his very thorough and interesting description, which is illustrated throughout with photographs and detail drawings of all parts of this large installation.

Electric Launches at Chicago.—The contract for furnishing and running a fleet of electric launches for carrying passengers on the lagoons at the World's Fair, has been finally awarded to the Electric Launch and Navigation Company, of New York. The company will be required to build 40 launches, and the Exposition Company will receive one-third of the gross receipts.

Aluminium.—A valuable discovery of white clay, very rich in alumina, has recently been discovered near Cleveland, Queensland. Some excellent specimens of pottery have already been made from this clay, says a Melbourne technical paper, and a quantity has been shipped by the "Jelunga" to England, instructions having been sent to have it tested at the Birmingham Aluminium Works.

Bristol.—Mr. Rienzi Walton, Local Government Board inspector, has held an enquiry at Bristol relative to the application of the Town Council for permission to borrow £66,000 for the purpose of electric lighting. The town clerk explained the position, and said that walls and foundations had been erected. Mr. Preece attended and explained the plans. There was no objection to the application.

Birmingham Electric Cars.—A correspondent of the *Birmingham Daily Post* thinks it would be much better to run much lighter electric cars at Birmingham and run them more frequently. To prevent overcrowding at the centre of the town, in Navigation-street, he suggests the cars might be run twice from here to Wellington-road to once that they are run from Wellington-road to Bournebrook.

Technical Education in India.—His Highness the Nawab of Joonaghur, says the *Indian Engineer*, has subscribed 10,000 rupees to the building fund of the Sind Madresseh tul-Islam at Kurrachee, a magnificent building costing 2,000,000 rupees, consisting of about 40 rooms, and having accommodation for about 1,000 students, prayer halls, and a factory for technical education, which is a part of the system of the Madresseh education.

Brazil.—Tenders are invited for lighting the city of Belem do Gram-Para, United States of Brazil, by gas or electricity. Particulars can be had on application to the Brazilian Legation, 55, Curzon-street, Mayfair, London (where a plan of the city may be seen), or to the Brazilian Consul General, 6, Great Winchester-street, London, E.C. Tenders are to be sent by 30th November to the office of the Secretary to the Municipal Council of Belem do Gram-Para.

Cheap Gas.—Dr. Auer's mantle for incandescent gas lamps has been improved and perfected, and it is said that 50 c.p. can be produced at 20 per cent. less consumption than with ordinary gas burners. The competition with electricity is severe, if we are to believe the report that in Vienna the hotels prefer this lamp to electric light. However, the Wurtemberg factory of the Edison-Swan lamps can now supply incandescent electric lamps at one shilling each.

Underground Conduits for Chicago.—The Love system of electric traction, which we have recently described, was made the subject of a company with 10,000,000dol. capital. This has been bought up, we hear, by a combination of Philadephia, Boston, and Baltimore financiers, including Mr. Elkins and Mr. Widener, whose purchases in Chicago railway stock have sent those securities up very considerably. The bearing of these purchases seems evident.

Merthyr.—At the ordinary meeting of the Merthyr Tydfil Board of Health, held last week under the presidency of Mr. Thomas Williams, J.P., a motion was introduced by Mr. E. P. Biddle in favour of obtaining a provisional order under the Electric Lighting Act. He pointed out that they were now paying £1,500 a year for gas. Mr. V. A. Wills seconded, and the Board were unanimously in favour of the project, but, in the absence of the clerk, it was decided to adjourn the matter for a month.

Mains for Oldham.—Tenders are required for making and fixing concrete culverts and the laying of electric conductors, for the Oldham Corporation. Specifications and drawings can be obtained on application to Mr. Alex. B. W. Kennedy, 19, Little Queen-street, Westminster, or to the Town Clerk, Town Hall, Oldham. Tenders must be delivered to Mr. A. Nicholson, town clerk, by 2nd September. A fee of one guinea will be charged for the specifications and drawings, which will be returned on receipt of a bona fide tender.

Croydon.—Offers are invited for the transfer of the powers granted to the Council under the Croydon Corporation Electric Lighting Order, 1891. Tenders should state the terms offered, the system of lighting proposed to be adopted, and it is essential that an option should be reserved to the Council of repurchasing the undertaking upon terms to be named. Tenders should be sent to Mr. C. M. Elborough, town clerk, Town Hall, Croydon, endorsed "Tender for Electric Lighting Order," by 11 a.m. on September 15.

Leicester.—The Gas Committee of the Leicester Town Council invite schemes, together with tenders, plans, and specifications, for the supply of electricity to their "limited area" in the centre of the town. A plan of the town and of the area to be lighted and other particulars can be obtained from Mr. A. Colson, M.I.C.E., engineer, Gas Offices, Millstone-lane, Leicester, upon payment of £5. 5s., which will be returned on receipt of bona fide tender. Tenders, addressed to Alderman Lennard, chairman, and endorsed "Tender for Electric Lighting," to be delivered by 11 a.m. on September 8.

Heckmondwike.—Mr. W. B. Hutchinson, C.E., electrical engineer to the Heckmondwike Board, has returned the cheque for £10 for preparing specifications as not in conformity with his arrangements. The Board have referred to the resolution, and sent back the cheque with a copy of resolution. Mr. Rhodes thought the amount was to be merged in the commission, but Mr. Blackburn said commission was never mentioned. A long discussion was held on the establishment of the central station, but the whole question was eventually referred to a public meeting of the ratepayers.

Electric Tanning.—A writer in a French paper states that all the strayed dogs taken up by the Paris police and left unclaimed are, after being killed, handed over to an enterprising manufacturer, by whom the skins are tanned by electricity. Instead of taking seven or eight months to transform the skin into leather, as is the case by the ordinary system, electricity does the work in three or four days. The leather so tanned, moreover, it is asserted, is much better than that manufactured by the ordinary process, and when made up into ladies' boots and shoes is much admired for its soft and delicate qualities.

Fleet-street Lamps.—Fleet-street for some time back has been much encumbered on the pathway by the excavation of trenches and laying of pipes for the City electric lighting mains. Now all is smooth, and the line of scores of pipes of all sizes is simply indicated down the pavement by a wide joint in the asphalte. Wires have been drawn in by a chimney-sweep arrangement of flexible cane rods, and now all is quiet again. Down the street at intervals are rising the large bases of the electric lamp posts, rough painted red, and we may evidently expect to have light in our darkness before the fogs come round again.

Waterford.—The citizens of Waterford are not content to sit down under the weak-kneed policy of their Town Council with regard to the proposed abandonment of the electric light after many years' service. A public meeting has been called, and strong protests are to be made. Alderman Redmond has done good work in calling attention to the question, and has published very favourable opinions upon the electric light from Dublin, Bray, Carlow, Kilkenny, and Larne. Waterford was the first town in Ireland to adopt the electric light, and it will be a shame if the machinations of the gas supporters force it to be the only one to abandon the light.

Factor of Public Satisfaction.—Mr. Preece, in the evidence printed in the Electric and Cables Railways Report, said there was a curious thing which had developed in the United States with reference to electric railways, which is that the electrically-worked railways have always increased the traffic so much, that the term "factor of public satisfac-

tion" has now been introduced. In the West End railroad of Boston, 112 miles in total length, running about 300 cars, it is found that in the same districts the electric cars have carried an increase of 44 per cent.—that is, they are earning 44 per cent. more receipts, they are running 33 per cent. more cars, and each car carries 15 per cent. more people, and they call this percentage of increase the factor of public satisfaction.

Huddersfield Sewage Works.—At the Huddersfield Town Council last week the Health Committee's minutes were considered, showing that tenders, 20 in number, had been received for the fixing of an electric lighting plant at the sewage works at Deighton, and it was resolved that the tender of Messrs. Crompton and Co., Limited, of Mansion House-buildings, London, E.C., at £900, be accepted. After much objection by Councillor Chrispin to the expense, it was explained that gas would cost £150 a year, and the interest and maintenance of electric light only about £50 a year, as the heat from the destructor could be utilised. The works at Wolverhampton, visited by the committee, were lighted in this way. The minutes were passed and the tender accepted.

Printing by Electricity.—We received yesterday a copy of the *Birmingham Daily Gazette*, which has been printed, cut, and folded by the aid of electricity. We believe this is the first daily paper to be so produced and by current from a central supply station to replace steam power. A complete plant has been put down by Messrs. Fowler, Lancaster, and Co., for driving the whole of the machinery by electricity, and with current from the main of the Birmingham Electric Supply Company at the usual pressure of 110 volts. Thursday was the first printing of an entire edition of two papers published by the proprietor of the *Gazette*—the *Birmingham Daily Gazette* and the *Birmingham Weekly Mercury*—and henceforth the papers will be so produced. The two larger machines produce up to 20,000 papers per hour each.

Electricity in Agriculture.—We have several times alluded to the experiments of Mr. Rawson, of Boston, U.S., on the electric forcing of lettuces and other crops by electric light. A recent report states that the effect of this illumination every night in hastening the maturity of crops of lettuces is such that a single crop will pay for the cost during an entire winter. Prof. Bailey, after visiting the establishment declares his belief that the electric light will probably become a factor in vegetable forcing. One of the 13 houses devoted to this crop covers nearly a third of an acre, and from this covered space the cultivator takes at one crop as many as 2,000 dozen heads of lettuces twice the size of those ordinarily seen in the markets. The light used in this case is stated to be three 2,000-c.p. arc lights, which are kept shining all night throughout winter.

Telephoning to New York.—We gave last week a short note on a new invention for submarine cable relays, invented by M. Willot, for cabling direct from Paris to Algiers. Something more wonderful is at hand, if we are to believe the Paris *Figaro*, which says: "The great difficulty in the way of long-distance telephonic communication under water has now disappeared. In a few weeks messages will be transmitted as quickly and as easily from Paris to New York as from Paris to Versailles. This discovery, which is of great economical importance, is due to M. Willot, inspector of telegraphs at Paris. As soon as the necessary apparatus has been installed, M. Willot expects to be able to telephone from Paris to New York." We hope this new discovery will not resolve itself into a further application of cable relays to the Atlantic lines." *Figaro* distinctly says "telephonic communication." But it is a little hazy about the spelling of the inspector's name, so perhaps "telephonic" means simply "telegraphic" after all. Nevertheless, rumours have reached us time and again, even from one of our highest authorities in electrics, that determined attempts were to be made soon in Atlantic telephony, and that he was convinced the thing was practical—Mr. Preece's formula notwithstanding. We live in hope.

Cyrus Field's Will.—Cyrus W. Field had a large number of articles of historical interest in his possession at the time of his death. He leaves the paintings connected with the Atlantic cable laying to the New York Historical Society; and he leaves to his children (to be drawn for by lot) the gold medals presented by Congress, the Paris Exhibition, the merchants of New York, the State of Wisconsin and other bodies, the decoration presented by the King of Italy, the table on which the contract was signed, March 10, 1854, for connecting England and America by cable, together with the chair and other articles used on this memorable occasion, and the interwoven flags of England and America which floated at the masthead of the "Niagara" in the expeditions of 1857 and 1858, and of the "Great Eastern" while the cables of 1865 and 1866 were laid.

Electrical Fire Brigade Apparatus.—A full parade of the Bradford Fire Brigade took place on Tuesday for the testing of the new electrical apparatus, erected in order to obviate the necessity of ringing up the fire brigade. The installation is connected with the quarters of the superintendent, and with the residences of the permanent members of the brigade, who have been provided with quarters just opposite the fire station. The switchboard is placed in the dayroom, and immediately a telephonic communication is received from the Town Hall the whole of the 10 firemen can be summoned from their homes by two moves of the hand. The superintendent can also be called up at the same time. The electric switches consist of a small lever with a projecting knob, and they can be either moved separately or together, calling up either the 10 men or just as many as the occasion may be thought to require. Above the switchboard there is an index board with a black dial pierced with 20 holes. As the men are summoned a red disc appears in the eyelet, and this remains there until the fireman answers the call. When he does so there is a switch which he turns on, and the red disc disappears in the index frame. This experiment was witnessed by members of the Corporation, and was highly satisfactory.

Electro-Medical Apparatus.—Medical electricity is taking a very important position in hospital and private practice, as may be easily seen in the illustrated list of apparatus for this purpose recently issued by Mr. K. Schall, of 55, Wigmore-street, W. Mr. Schall has great facilities for producing useful and practical electrical appliances, having supplied a very large number of hospitals and medical men with instruments, batteries, and apparatus, many of the patterns having been designed by the doctors themselves for special requirements. Induction coils of various patterns are, of course, largely used, batteries for cautery and electrolysis, with indiarubber-sheathed platinum needles for destroying tumours. A special piece of apparatus we recently mentioned, made by Mr. Schall, is a small transformer set for obtaining currents for medical purposes from the ordinary alternating-current circuits. Lamps for investigation of the larynx, and ingenious arrangements for illumination, direct or by reflection, of the abdominal cavities, the ear, and the mouth, are illustrated carefully, and electric motors for dental or other operations are shown. Altogether the catalogue is a credit both to the medical profession and Mr. Schall, and its usefulness is not a little enhanced by a carefully written introduction, giving in a

brief space a considerable amount of practical information upon electrical subjects. The list of references includes the principal hospitals and some hundreds of prominent medical practitioners.

Croydon Tramways.—The chairman of the Croydon Tramways Company, Mr. W. J. Carruthers-Wain, at the recent meeting of the company referred in the following terms to the question of electric traction on their line: "I told you at the last meeting that we had made arrangements with the Electric Tramcar Syndicate on a system of which I am very fond—namely, 'Heads I win, tails you lose.' They were to run a certain number of cars at a fixed figure per mile, and the result to us has been satisfactory. The greater the facilities you give the public, the greater will be the advantages to you. You increase your traffic because you give the public, first of all a novelty, and when they have got tired of the novelty they find that the improved mode of traction in itself is a better method of getting about to their work or pleasure than the old types. I am sorry that from circumstances with which we have nothing to do, the Electric Tramcar Syndicate is not at present working that system of cars; but I hope that some arrangement will be made by them whereby they will be able to continue. I should like to see the whole of the line equipped and worked on the same terms, because you and your directors would be freed from responsibility and anxiety, and you would have nothing to do but to assemble every half-year to hear the declaration of the dividend." In reply to a question by Mr. Forbes, the chairman further said the Electric Syndicate, who had run cars upon the company's line with satisfactory results, were undergoing what was called domestic reconstruction at the present time, and he had no definite proposition from them. When their arrangements were complete, the board would endeavour to make an arrangement with them if the board were assured that they could carry it out.

Telegraphs and Telephones.—From the Postmaster-General's report, recently issued, it appears that the increase in the number of telegraphic messages of all kinds over that of previous years is 3,276,269, or 4 9 per cent. The London local telegrams show an increase of 335,152, or 6 per cent., the number being 6,081,276 as compared with 5,746,124 in 1890-91. An important alteration has been made in connection with the delivery of telegrams at night in the outlying portions of large provincial towns after the hour for closing the local branch office. Formerly porterage used to be charged from the head office on such telegrams, but now they are, like other telegrams, delivered free within the area of the ordinary free delivery of the local office. With regard to telephones, it is stated that the results of the working of the London Paris telephone, which was opened on 1st April, 1891, have been satisfactory. The number of conversations has increased from 1,221 during the month of April, 1891, to 2,157 in April, 1892, and it has been necessary in consequence to allocate a second circuit for the purpose. The charge is 8s. for a conversation of three minutes. As regards the acquisition of the telephones the Postmaster-General says: "One of the largest companies concerned has bought up most of its rivals, and gone a long way towards constituting the monopoly which Parliament desired to prevent. The expiration of the patents and the dissatisfaction evinced by the public at the want of development of the telephone system necessarily obliged the Government to examine the whole subject. Serious difficulties presented themselves, and the Government decided that the Post Office alone should possess the trunk wires between towns and co-operate with the companies in rendering additional services to the public. The object aimed at is to develop and cheapen the telephone service, as explained in the Treasury minute which was laid before Parliament in May last. A Bill founded upon the minute is under the consideration of Parliament."

Telephone Statistics.—From a census report on telephone companies in the United States during the census year (1890), it is possible, says the *Times*, to gather some idea of the enormous development which this new industry has undergone during the past decade. It is important to remember that at the beginning of the previous census year, 1879 80, the business of telephone companies in the United States amounted to little or nothing. During that year the business passed through the stages of an unprecedented development. This is strongly brought out by the fact that in 1880 there were no less than 148 telephone companies or firms reported as engaged in the business. In 1890 this number was reduced to 53; but this is the only respect in which a reduction is reported In every other respect the statistics show an enormous increase. The total amount invested in the business in 1880 was 14,605,787dol., in 1890 it was 72,341,736dol.; the gross earnings in 1880 were 3,098,081dol, in 1890, 16,404,583dol.; the gross expenses in 1880 were 2,373,703 dol., in 1890, 11,143,871dol.; the net earnings, which in 1880 were 724,378dol., in 1890 were 5,260,712dol; the number of exchanges had increased from 437 in 1880 to 1,241 in 1890; the number of telephones and transmitters, which in 1880 was 108,638, in 1890 was 467,356; in 1880 there were 34,305 miles of wire, in 1890 there were 240,412 miles; the number of employés in 1880 was 3,338, in 1890 it was 8,645; the number of subscribers, which in 1880 was 48,414, had increased in 1890 to 227,357. No record was kept of the number of conversations during the former year, but in 1890 they reached the enormous total of 453,200,000. The report points out, moreover, that, interesting as are these statistics, it is impossible by such methods to convey a proper representation of the actual changes that have occurred in the business of operating telephone companies during the decade from 1880 to 1890. Improvements in instruments and exchange switchboards, changing from grounded to metallic circuits, placing wires underground, extension of lines to extra territorial districts, and, finally, the introduction of long-distance service, combine to make the service rendered in 1890 more valuable and satisfactory to subscribers than the service rendered in 1880.

Strowger Automatic Telephone Exchange To dispense with the telephone girl entirely would be a sufficiently radical reform in central exchange practice, yet no less a change is proposed by Mr. Strowger, who has designed and perfected an automatic telephone exchange. If all that is claimed for it can be realised, then telephone directors may bless their stars and draw their dividends in peace. A picture is given in the *Electrical World* of August 13th of a Strowger central exchange. No switchboards are to be seen, no rows of listening ear-capped girls, only shelves of clock-like instruments and their batteries. The manager's chair even is empty, and the only person is a mechanic fitting up a new instrument. The method of working is simple enough. On the telephone shelf in the subscriber's office is a keyboard with five keys. Suppose he wishes to speak with No. 1,423. He presses the thousand key once, the hundred key four times, the ten key twice, and the units key thrice, and he is connected. No shouting, questions, or listening. To make all safe, a dial in front of him shows the number on his own telephone as well. He can now ring up and converse to his heart's content. If another subscriber wants to join in he can do so, but only to the extent of ringing the bell—he cannot speak through, and the first subscriber can finish his talk, and then, cutting out by a

release key, rings on to No. 2, who, we suppose, is waiting. The instrument which accomplishes all this is small, only 6in. by 4in. by 4in., but is naturally somewhat complicated. It has a disc of vulcanite, provided with circular rows of perforations, 100 in each row, $\frac{1}{10}$in. apart. Through these perforations extend wire connections to the main line wires, so that the wire of every subscriber comes to the instrument, passing up and ending in a good metallic contact. A moving arm or needle makes contact with these points. A combination of ratchets and pawls enables any contact to be made at will. When the conversation is finished, the telephone is hung up and the release key pressed. This sends a current, energises a magnet, and unlocks the ratchets and pawls, which return to zero. Each wire has, of course, one of these instruments, and as an instrument for 10,000 subscribers would have a dial of only 10in. diameter, it is claimed that quite large exchanges could be managed entirely without operators in attendance. Even if it should not be practicable in the larger and busier exchanges, there is a wide field of usefulness for such a system in the local exchanges and private telephone installations.

Irish Water Power.—Ireland is somewhat like Switzerland with regard to its large latent resources in water power, though unlike in the little use that is made of them, and it may be worth while at the present time to draw further attention to this fact. Not only for electric installations, now, we are happy to say, rapidly increasing, but for many manufacturing purposes by means of electric transmission might these waste powers in the future be usefully employed, as they have long been in Switzerland, and it would be well if electrical engineers in Ireland were to do more in trying to arouse public and private interest, by means of the papers and otherwise, in the sources of revenue that lie around waiting to be tapped. Without coal and without ports Switzerland has been able, by means of its lavish water supply, to erect and carry on fine factories and compete with other countries successfully in manufacturing products. A Foreign Office report just published—"Report on the Condition of Labour in Switzerland," Eyre and Spottiswoode, 6d.—brings the position out plainly in the following paragraph: "The manufacturing interests of this country mainly depend upon their rich water resources. Of the 2,322 factories which employed motive power at the close of 1888, 1,114 exclusively employed water power, and only 658 exclusively steam power, while 457 employed both water and steam; and, taken altogether, these 2,322 factories used 54,243 h.p. of water and 27,432 h.p. of steam, and only 717 h.p. of gas. The facilities which science is daily multiplying for the transmission of force by electricity, recently exemplified by the Lauffen transmission exhibited at Frankfort, are likely still further to accentuate this special feature in Swiss industry." We know that since 1888 immense strides have taken place in this department of science, and Switzerland now stands with Italy at the head of the European countries in the utilisation of natural forces. In America equal progress prevails, and in this and other commercial and educational departures American authorities are careful to have full reports from the centres where most efficiency and activity is found. Special commissions of professors, architects, and engineers are sent over from time to time to report fully upon all points that can aid progress. If a few travelling commissions could be arranged by the Irish colleges, or other authorities, to send over students and engineers to study and report upon the utilisation of water power in Swiss industries, this might give rise to a development of electric transmission plants that would benefit largely the financial and commercial aspects of the sister country.

Birmingham Electric Cars.—In a very full report that Mr. Carruthers-Wain (managing director) has made to the chairman of the Birmingham Central Tramways, he thus refers to the electric traction in the Bristol-road. He says: "I regret that my own idea as to the traffic upon this line has not been justified by the result. You will remembered that my estimate of the traffic was an average, taking the year through, of £250 per week, but the failure to reach this figure arises from causes with which you are well acquainted. There is no doubt that if we had had the means at our disposal to have conveyed the traffic, my estimate would have been fully justified. One set of the new batteries has been delivered. Had we been able to maintain the service originally contemplated, the difference in traffic would have been £2,700, which would have converted the deficit into a profit of £1,000. The undue strain put upon the rolling-stock, owing to the lines having been so constructed by the Corporation that they were too wide for the cars—*i.e.*, that they were out of gauge to the extent of as much as 1½in., resulting in the constant breakage of axles and wheels, and the consequent effect upon the working parts, and the enormous consequent strain upon the batteries, which were practically trying to grind a new groove in the metals—has naturally increased the maintenance charges to a very high figure. Again, the charge for permanent way is monstrous. It is absolutely impossible that ordinary repairs to a line which has only been constructed two years could in the past 12 months cost the sum of £1,352. That this is so is shown by the fact that on the small portion of line belonging to us beyond the city boundary on this route we have spent practically nothing during that time. The electric expenses in fuel will show a reduction this year. The new boiler will be able to do the bulk of the work, and owing to the price of fuel generally being reduced, we have been able to make a contract more advantageous to the company. After making many enquiries we have negotiated an arrangement with a company under which they guarantee, after the first cost for batteries is paid, to keep them in repair, and renew them when required for one penny per car mile run. The recent reduction in the electric service (which has, as the daily returns show, worked for the past few months with scarcely a hitch) has been due to the diminution of the number of batteries available for working, owing to others being worn out; and during that time the desire of the Board was not to incur indefinite expenses in batteries pending the investigations then in progress. A suggestion has been made that the electric and cable cars should be canopied. The company would have no objection if the Board of Trade and local authorities would agree to it, although it would add considerably to the weight, and therefore to the cost of haulage, but the local authorities have hitherto declined to allow canopies to be placed upon the cable cars. The following figures show the percentage of expenses to receipts in each branch for the year 1892: Steam, 75 per cent.; horse, 39 per cent.; cable, 50 per cent.; electric, 116 per cent.; total, 75 per cent. The gross receipts for the year ending 30th June are £152,238. 15s. 2d., as compared with £106,000 for 1887, and show an increase of £46,238. 15s. 2d. and a profit of £37,028. 1s. 9d., as against £18,000 for 1887, this being an increase of 43·62 per cent. on the receipts and 105·71 on the profits—*i.e.*, while we have increased the traffic by half as much again, we have doubled the profit. The whole of the departments have worked exceedingly well during the past year. There have only been trivial complaints from the public, and those mostly unjustifiable."

A BATTERY PROBLEM.

ON THE DETERMINATION OF THE RESULTANT E.M.F. OF TWO OR MORE CELLS JOINED PARALLEL.

BY W. A. RUDGE AND R. ALLEN, M.A., B.SC.

If the poles or terminals of a cell be joined by a wire, the available E.M.F. at the terminals will be reduced, and the reduction of the E.M.F. will bear a definite relation to the resistance of the wire as compared with the resistance of the cell. Let A B be the terminals of a cell of E.M.F., E_1, R_1 = resistance of cell, R_2 resistance of wire. On joining A B by R_2 the E.M.F. between those points will be reduced (the decrease of E.M.F. being inversely proportional to) in the ratio of R_2 to $R_1 + R_2$.

Let E = resultant E.M.F. after connection, then

$$E = E_1 \times \frac{R_2}{R_1 + R_2}, \text{ and } E_1 R_2 = E(R_1 + R_2).$$

If R_2 be very great, the E.M.F. is practically unaffected; if $R_2 = 0$, then the E.M.F. is reduced to 0 at the points A B.

Proof.—Let A E_1 B C be a circuit containing a cell at E_1, the points A and B being the terminals of the cell, C the wire used to join the terminals of cell A and B between which the E.M.F. is measured.

Fig 1

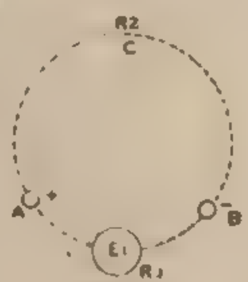

Fig 2

1. Consider the wire C removed. The cell will now have an E.M.F. = to E_1; as no current is passing E_1 will be independent of R_1.

2. Join A B by C of resistance R_2. A current will now flow, and the difference of potential between A and B will be lowered, the potential falling through A C B and A E B respectively, at rates inversely proportional to the resistances R_2 and R_1, therefore the available E.M.F. between A and B will be reduced in the ratio of R_2 to $R_1 + R_2$.

Then resultant E.M.F. $= E_1 \times \dfrac{R_2}{R_1 + R_2}$.

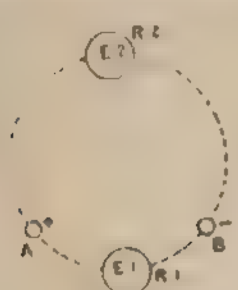

Fig 3.

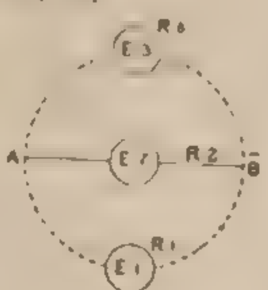

Fig 4

Consider the case when the external resistance R_2 contains an E.M.F. acting in the opposite direction to E_1 (Fig. 3)—*i.e.*, joined parallel. Then neglecting E_2, the available E.M.F. due to $E_1 = E_1 \times \dfrac{R_2}{R_1 + R_2}$, and neglecting E_1, the available E.M.F. due to $E_2 = E_2 \times \dfrac{R_1}{R_1 + R_2}$, and the total resultant E.M.F., E, due to both cells

$$= \frac{E_1 \times R_2 + E_2 \times R_1}{R_1 + R_2} \quad . \quad . \quad . \quad . \quad \text{(i.)}$$

But if $E_1 = E_2$, as is the case when two cells of similar construction are taken, then resultant E.M.F.

$$= \frac{E \times R_2 + E \times R_1}{R_1 + R_2}$$

= E, *which proves that when two cells of similar construction are joined parallel the E.M.F. is equal to that of one only.*

Combination of three cells of E.M.F.'s, E_1 E_2 E_3, and resistance, R_1 R_2 R_3, as Fig. 4. Neglecting E_2 and E_3, E_1 will be joined by a resistance, $\dfrac{R_2 R_3}{R_2 + R_3}$ ∴ available E.M.F. between A and B due to

$$E_1 = \frac{E_1 \dfrac{R_2 R_3}{R_2 + R_3}}{R_1 + \dfrac{R_2 R_3}{R_2 + R_3}} = \frac{E_1 R_2 R_3}{R_1 R_2 + R_2 R_3 + R_3 R_1},$$

Similarly, that due to $E_2 = \dfrac{E_2 R_3 R_1}{R_1 R_2 + R_2 R_3 + R_3 R_1}$,

and that due to $E_3 = \dfrac{E_3 R_1 R_2}{R_1 R_2 + R_2 R_3 + R_3 R_1}$,

and the resultant E.M.F. of the three cells

$$= \frac{E_1 R_2 R_3 + E_2 R_3 R_1 + E_3 R_1 R_2}{R_1 R_2 + R_2 R_3 + R_3 R_1} \quad . \quad \text{(ii.)}$$

If four cells be taken of E.M.F. E_1 E_2 E_3 E_4, and resistance R_1 R_2 R_3 R_4, and joined parallel as before, then resultant E.M.F.

$$= \frac{E_1 R_2 R_3 R_4 + E_2 R_3 R_4 R_1 + E_3 R_4 R_1 R_2 + E_4 R_1 R_2 R_3}{R_2 R_3 R_4 + R_3 R_4 R_1 + R_4 R_1 R_2 + R_1 R_2 R_3} \quad \text{(iii.)}$$

and so on.

In (ii.) let $E_1 = 0$, then E.M.F.

$$= \frac{E_2 R_3 R_1 + E_3 R_1 R_2}{R_1 (R_2 + R_3) + R_2 R_3} = \frac{E_2 R_3 + E_3 R_2}{R_2 + R_3 + \dfrac{R_2 R_3}{R_1}} \quad \text{(iv.)}$$

In (iii.) let $E_1 = 0$, then E.M.F.

$$= \frac{E_2 R_3 R_4 + E_3 R_4 R_2 + E_4 R_2 R_3}{R_3 R_4 + R_4 R_2 + R_2 R_3 + \dfrac{R_2 R_3 R_4}{R_1}} \quad . \quad . \quad \text{(v.)}$$

which gives formula for E.M.F. of two or three cells when there is an external resistance R_1.

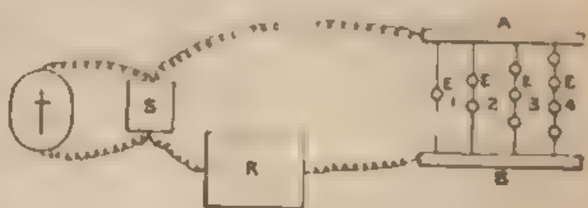

Fig 5

If R_1 be very great, then (iv.) and (v.) will become

$$\frac{E_2 R_3 + E_3 R_2}{R_2 + R_3}$$

and

$$\frac{E_2 R_3 R_4 + E_3 R_4 R_2 + E_4 R_2 R_3}{R_3 R_4 + R_4 R_2 + R_4 R_3}$$

For the experimental proof of the above a number of "Minotto" cells were prepared and arranged in four groups.

Groups.*	Consisting of	Relative measured E.M.F.	Relative measured resistances.
(1)	1 cell	1	1
(2)	2 cells	1·94	2
(3)	3 cells	2·92	4·25
(4)	4 cells	3·87	5·85

* The groups are afterwards considered as single cells.

The circuit was arranged as Fig 5. A and B were two brass rods fitted with binding screws, so that any combination of cells could be easily and quickly made. The resistance of R was altered for each experiment, so that the total in the circuit was 10,000 ohms. The galvanometer being a high-resistance reflecting one, the E.M.F.'s were considered to be proportional to the deflection.

RESULTS OF EXPERIMENTS.

Combination of cells.	Observed E.M.F.	Calculated.
Two cells.		
1 and 2	1·33	1·31
1 and 3	1·34	1·34
1 and 4	1·43	1·42
2 and 3	2·28	2·22
2 and 4	2·42	2·43
3 and 4	3·26	3·26

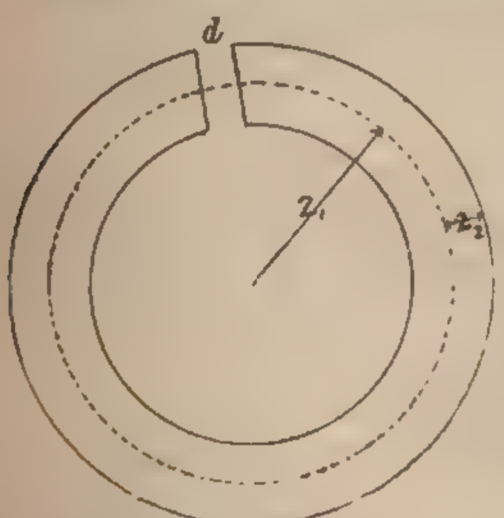
Three cells.		
1, 2, 3	1·51	1·51
1, 3, 4	1·64	1·63
1, 2, 4	1·53	1·57
2, 3, 4	2 51	2·52
Four cells.		
1, 2, 3, 4	1·71	1·70

The formulæ would probably apply in the case of dynamos or other sources of E.M.F., but we have had no opportunity of experimenting in this direction.

ON LEAKY MAGNETIC CIRCUITS.*

BY DR. H. E. J. G. DU BOIS.

Ever since the Hopkinsons' researches, a great many experiments on magnetic circuits have been made; mostly, however, in the form of measurements on dynamos of various types. Now the results obtained with a particular dynamo may offer a certain degree of interest, especially to its maker; but the utmost care has to be taken in generalising from such data. Quite apart from the consideration that ballistic measurements on dynamos suffer under the undue proportion their time-constant bears to the period of even the slowest ballistic galvanometer, dynamo circuits are not designed for giving interpretable scientific results, but for economy. For all these reasons it seemed to me a useful thing to thoroughly overhaul the whole subject by theorising and experimenting on the simplest conceivable type of magnetic circuit, and though the subject of these circuits has been amply discussed for the last 10 years, I venture to hope that its importance may warrant my bringing the first results of this rather lengthy investigation before Section A.



Consider a split-ring, magnetised by a uniform peripherical field. Let r_1 be the radius of the central circle, r_2 that of the circular section, d the width of the air gap. Assuming, then, as a first approximation that the magnetisation is uniform over the whole section of the ring and its direction everywhere peripherical, it may be shown† that:

$$N = \frac{2\left(d + r_2 - \sqrt{d^2 + r_2^2}\right)}{r_1 - \frac{d}{2\pi}} \quad . \quad . \quad . \quad (1)$$

where N is the well-known "demagnetising" factor which determines the amount of shearing over of the magnetic curve.

According to a theorem first enunciated by Kirchhoff, the above state of affairs will strictly occur when the external magnetising field becomes infinite; the direction of the lines of magnetisation is then bound to coincide with that of the applied lines of force. The values of N actually found must therefore approximate to those given by (1) as the field increases.

For weaker fields an exact calculation is impossible, but it may be stated that in this case

$$N = \frac{2\,d\,n\left(\frac{d}{r_2}\right)}{r_1 - \frac{d}{2\pi}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where the functional notation $n\left(\frac{d}{r_2}\right)$ means a number which is a function only of the ratio of width to radius of air-gap, independently of the rest of the circuit. This number, n, is practically equal to the reciprocal of the leakage coefficient as defined by the Hopkinsons.

It may be remarked that both the expressions given converge towards the simple form

$$N = \frac{2\,d}{r_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

when the width of the air-gap diminishes more and more towards zero. In this case the value of n is unity, whereas for wider gaps n becomes a fraction. Moreover, the number n, as well as the factor N, vary somewhat with the magnetisation in a way which it must be left to experiments to determine.

These were carried out, under my advice, by Mr. H. Lehmann. A ring, about 15 cm. mean diameter and 2 cm. thick, was turned out of best Swedish plate and well annealed. It was wound uniformly all round with primary and secondary wire, and its normal curve first taken in the unsplit state. It may be remarked that curves of ascending reversals were taken throughout, the thickness of the iron giving so much time-lag that the step-by-step process would not give correct results. The magnetising field could be pushed to 400 C.G.S., the ring being immersed in a trough of iced petroleum.

The ring was now cut, beginning with a very narrow gap of a few tenths of a millimetre width. A small brass disc was fixed in the gap to prevent the iron from yielding to magnetic attraction, and a small secondary wound so as just to enclose the lines of induction crossing the air. Another auxiliary secondary coil could be moved around the ring so as to explore the leakage.

The general results may be summarised as follows:

1. For the very narrowest gaps the formula (3) holds, as it should.

2. As the width increases (2) becomes applicable; the values of n found from the throw due to the auxiliary secondaries, when substituted into (2), give numbers for N in good agreement with those found by the "shearing backwards" graphical process.

3. Both n and N remain practically constant up to values of I, about half the "saturation" value—*i.e.*, 850 C.G.S.; for higher magnetisations they begin to show an *increase*, N approaching to but *not* superseding the value given by (1), as was theoretically predicted above.

4. As a rule the *mean* magnetisation was deduced from the throw due to the principal all-round secondary; this was almost identical with the result given by the auxiliary secondary when diametrically opposite the air-gap. And by further exploration with this secondary it was found that an appreciable leakage began to occur only at about one-eighth of the circumference on both sides of the gap.

The numerical values of n within its range of constancy (which is the range of magnetisation mostly worked with) are of general interest, because they, or their reciprocals, depend only upon the ratio of width to radius of air-gap, as explained above. Moreover, it will hardly matter much whether the section of the gap be exactly circular so long as its area be the same; we thus obtain numbers of a certain utility in all questions of design where air-gaps occur. I prefer not to give the actual figures here, they being liable to slight corrections; they will soon be published in full in *Wiedemann's Annalen*, together with the experimental detail.

The result 3 that n finally *increases* with I, I consider to be fully proved by experiment; it corresponds to a final *decrease* of its reciprocal, the leakage coefficient. Now this is in complete disagreement with what is generally accepted as a dogma—viz., that leakage becomes more and more pronounced with larger inductions. This fallacy, as I cannot now help calling it, has generally been explained

* Paper read before the British Association at Edinburgh.

† See "Mathematical Theory of Ferro-magnetism," *Wied. Ann.*, xlvi., p. 494, 1892.

by the fact that the permeability of iron decreases, and so becomes more equal to that of the surrounding medium. If then Ohm's law held, there is no doubt but that more leakage would occur. But a true ohmic law does not hold in magnetism, or rather, the excellent results obtained by applying it in particular cases do not warrant its generalisation. Its complete failure to predict or explain in the present typical case may be hoped to bring home a little more care in its manipulation to those liable to grow too enthusiastic about magnetomotive force and reluctance.

On the other hand, physical theory is quite competent to explain the final decrease of leakage, which experiment has demonstrated to occur in the split-ring uniformly magnetised. For Kirchhoff's theorem already alluded to, in connection with the tangent law for the "refraction" of lines of induction at bounding surfaces clearly shows that those lines will tend to become more and more exactly peripherical as the applied field is being pushed up, thus diminishing the number of lines leaking away into the air.

In conclusion, it may be remarked that it is quite possible that leakage may yet increase in particular forms of circuits where the magnetising field is not uniform all round—*i.e.*, where coils are arranged in some haphazard way, more especially so if there be no coils near the gaps. It has to be borne in mind that on increasing the current in such coils the strong field so applied will finally overpower the self-demagnetising tendencies altogether, and arrange the lines of induction after its own fashion. Of course, exactly the reverse happens when weak fields are applied. I intend shortly to investigate this subject a little further by means of a large-sized ring electromagnet with 12 separate coils made from my designs by Messrs. Siemens and Halske.

ON A MAGNETIC BALANCE AND ITS PRACTICAL USE.*

BY DR. H. E. J. G. DU BOIS.

In a paper on "Magnetic Circuits and their Measurement," read to the Frankfort Electrical Congress in 1891, the principles of a magnetic balance were explained, with which magnetic curves of any material might be readily obtained in absolute measure. Theoretically it may best be defined as an electromagnetic system of variable configuration, the reluctance of which always naturally tends towards a minimum, the variations, however, remaining exceedingly small. I now propose to describe the instrument exhibited to the section; it is the outcome of a year's evolution of constructive detail. By means of a gauge belonging to the instrument, one test piece T, is cut to 15 cm. length and 1.128 cm. diameter,

* Paper read before the British Association at Edinburgh.

corresponding to 1 cm.^{2} section; the latter need not necessarily be adhered to if inconvenient, but has the advantage of obviating all further calculations, as will be seen below.

The coil C is 4π cm. long*, and wound with 100 turns, therefore near the middle it gives a field = 10 × current (in amps.). It will carry currents up to 30 amperes, which may be conveniently measured by the usual ampere meters; the corresponding range of field (0 to 300 C.G.S.) is all that is required in the great majority of cases. The test-piece is supported on two adjustable M plates, by means of which it may be readily set concentric to the coil, which is then slipped into position, the test-piece being automatically clamped by the plunger in the upright, V_2. Fig. 1 is a cut (one quarter of the natural size) showing the curved yoke, Y Y, of best Swedish iron playing over the stop, A, and screw, I. The latter is enclosed in a cap after calibration, so that the adjustment cannot be interfered with. P is a lead counterweight. Fig. 2 gives a perspective view of the instrument.

FIG. 1.

I have made a series of observations to find experimentally what function of the magnetisation of the test piece the resulting moment on the yoke (measured by compensating with the sliding weights) would prove to be. A small secondary was slipped over the middle of T, and connected to a ballistic galvanometer. It was found that the resulting moment was accurately proportional to I^2 (or B^2) up to values of $I = 1,300$ (or $B = 16,000$), with a test piece of 1 cm.^{2} section; this is all the range that is usually required; however, by using a somewhat thinner sample magnetisations up to 1,700 C.G.S. may be measured, as the tractive forces really depend upon the flux of induction through the test-piece only.

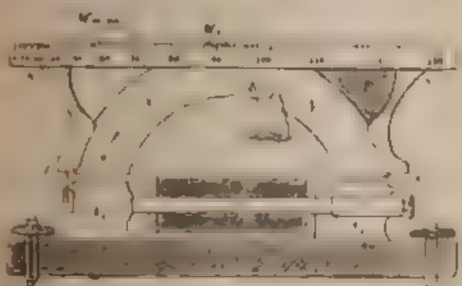

FIG. 2.

After this law had been experimentally established, it was evidently better to introduce a quadratic scale, along which two mutually independent weights, W_{100} and W_4, slide, of 100 and 4 grammes weight respectively. Accordingly the scale readings have only to be multiplied into the square roots of those weights—viz., 10 or 2—in order to obtain the absolute value of I in the sample. The smaller weight is used for the range $0 < I < 260$. It is then slid back to zero and measurements continued with the larger weight for $260 < I < 1,300$. The instrument does not indicate whether one is to take $+\sqrt{I^2}$ or $-\sqrt{I^2}$; but on plotting the results this becomes at once evident, one of the two points falling entirely outside the smooth curve joining the observations. It is therefore unnecessary to add a special permanently polarised arrangement with which to detect the direction of magnetisation.

The demagnetising factor, N, for a cylinder of dimensional ratio (length/diameter) 15 is about 0·12*). It is found in the balance to be reduced to 0·02, corresponding to the threefold ratio 45. This number was found by plotting the curve of a standard sample directly from the balance and shearing it backwards into coincidence with the normal curve obtained with a ring of the same material.

The result was, moreover, arrived at, that the usual rectilinear pseudo-axis of ordinates would do well enough up to half the saturation value, but that on the whole it was more accurate to introduce a generalised curvilinear shearing-base. This may be called an instrumental directrix, as it remains characteristic of the instrument when once determined by means of a standard sample; all the corrections due to the uprights, V_1 and V_2, the yoke, Y Y, the air spaces with their variable leakage, etc., are contained in it; it is used when ordinary unlooped curves of ascending reversals are being taken. In order also to correct for hysteresis of instrumental parts of the magnetic circuit, it is advisable to introduce two other directrices, the horizontal distance of which measures the coercive force of the apparatus. The left one is used for plotting ascending curves, the right one for the descending branches.

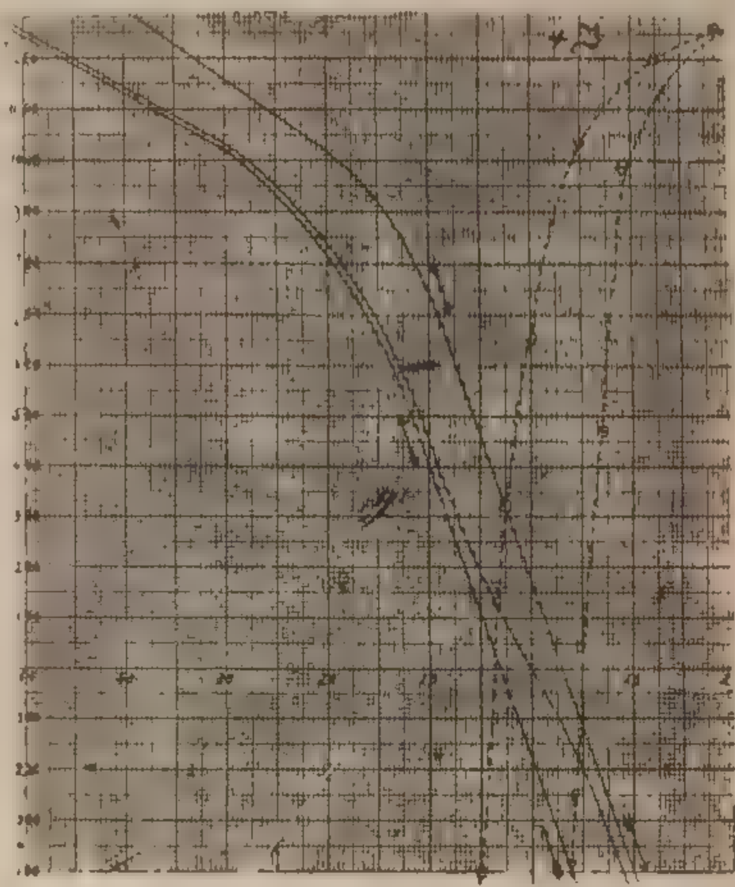

FIG. 5.—20,000 ergs per cm^3. Coerc. = 4. No. 9. Iron-Wire (annealed).

In conclusion, I may offer a few remarks on the practical use of the magnetic balance. The coil is placed in circuit with a reversing key, a good ampere-meter, one or two storage cells, and rheostats (preferably liquid) so as to admit of easily and gradually reversing, varying and reading the current between 0 and 30 amperes. In the first place, everything should be thoroughly demagnetised by diminishing reversals: accordingly, the yoke is slowly lifted by an arrangement provided for the purpose, while the reversing key is being quickly worked; it ought to remain in the lifted position when the instrument is not used, in order to spare the knife-edges, E. Then the coil is moved towards the observer and the test-piece gradually pulled out, reversing all the time.

* Really it is slightly shorter (12·2 cm.) to compensate the end effect.

* See the table in my "Mathematical Theory of Ferro-magnetism," *Wied. Ann.*, xlv., p. 498, 1892.

The method of taking readings will be sufficiently obvious from the above description; I will only add that, on account of magnetic instability, the position of the sliding weight is determined which will just pull the left-hand stop off the screw I, it has been found an unnecessary complication to introduce a secondary bell or telephone circuit as a criterion for the breaking of contact. The observer's ears and fingers afford a readier means, and after some little practice different observers alway find exactly the same reading to one or two tenths of a scale division (corresponding to a unit of magnetisation); this is more than sufficiently accurate.

The tenfold ampere and scale readings (or with the small weight, only double the latter) directly give abscissæ and ordinates respectively in C.G.S. units. The former are measured from the instrumental directrices as explained above; these are drawn on a transparent card belonging to the instrument, which is laid on the upper left-hand or lower right-hand quadrant of the squared paper, the plotting on which is thereby rendered as simple as when the usual method is followed. If the section of the test-piece is not 1 cm.^{2} it has to be measured, and the ordinates have still to be divided by it *after* the above process of plotting.

The dotted curves of Figs. 3, 4, and 5 were obtained with actual samples in the instrument exhibited. The full-drawn lines are the directrices, the middle one for ascending reversals is seen to considerably deviate from the straight line corresponding to $N = 0.02$ as the magnetisation increases beyond 850. From the malleable iron curve, Fig. 4, the first given for this material so far as I am aware, it may inferred that its magnetisation (for $H = 65$) is about 50 per cent. greater, and its coercive force as much less than those of ordinary cast iron. Fig. 5 was obtained with a bundle of 124 thin iron wires, representing a total cross-section of 1 cm.^{2}.

A NEW FORM OF WINDMILL FOR ELECTRICAL AND OTHER PURPOSES.*

BY PROF. J. BLYTH.

At the present time the employment of the form of energy known as the electric current to industrial purposes has become very extensive; and, in the near future, its application in that direction is likely to be still further increased. We have already many large private installations of the electric light. Every steamboat of any size is now electrically lit. In many places the current is used for the transmission of power. Already several large towns have adopted it instead of gas for street lighting, and the question of general house to house lighting is one whose solution only awaits a slightly greater economy in current production and distribution. It may be said that as yet the current is generated almost exclusively by dynamos driven by steam engines, so that it is merely a transformation of the potential energy of coal, and, so long as this is the case, it is obvious that any cheapening in its production can only arise either from an increase in the efficiency of the dynamo or of steam engine, or of both. Now these machines have attained so great an efficiency that there is scarcely any hope for much improvement in this direction. Primary batteries of several forms have been suggested and tried, but currents got from the oxidation of metals will always, I think, be too dear for practical purposes. Something may be expected from thermo-electric batteries, for here we have the direct transformation of heat into current electricity without the intervention of the wasteful middleman represented by the steam engine and dynamo. This, however, can hardly be said to have reached even the experimental stage.

Considerations such as these have led electrical engineers to look about and see if there may not be some other source of power at present unused, and which might be utilised for current production. Naturally, water power first suggests itself. The Niagara Falls have often been spoken about, and their available energy for that purpose calculated. In several places electric lights are run from water wheels where the fall happens to be near at hand, but in the great majority of cases the available falls of any size are so far from the centres of population that the cost of conducting the current almost prohibits their use. Much, no doubt, may be done by employing rapidly alternating currents of high voltage, and so diminishing the cross section of the necessary leads, but even then, when the distance is considerable, the cost of conduction comes in as a serious item. And, besides water power is not free. Although a fall may be unused just now, still, when it is proposed to use it, it immediately acquires a money value, and must either be vended or bought outright.

Next, after water power, comes the consideration of wind power, and it is about this that I am principally to speak. The wind is proverbially free, and is to be had everywhere, although it is of a very intermittent nature. Up till recently, this entirely precluded its use for current generation, as it was obviously impossible for it to work electric lights or do any kind of work where a steady current at a fixed time was required. But all this has been changed by the invention of storage cells or accumulators. These are now highly efficient, though a little too expensive; but disregarding the expense, we are now able to stow any quantity of electric energy and get a high return, even although a considerable time elapse between the storing and the using of it. No sooner was the accumulator invented than windmills for electric storage began to be thought of. At the York meeting of the British Association, Sir William Thomson suggested the construction of cheap windmills to run dynamos for charging accumulators, but, so far as I know, no practical trial was made till the summer of 1887, when I erected my first electric windmill in the village of Marykirk, Kincardineshire. At that time I procured a set of 13 accumulators and constructed a windmill of the old English type, having four arms and canvas sails. The length of the arms was about 14ft., and the sails were 8ft. by 3ft. The mill was provided with bevelled gearing at the top of a vertical shaft, and bevelled gearing below, so arranged that the driving wheel moved always in the same vertical plane, no matter in what direction the wind shaft pointed. The mill was turned into the wind by hand, having no tail or other gearing for keeping automatically head to wind. The dynamo was driven by a belt from the driving wheel, and with this I was able on two or three windy days to store my cells. Although the experiment was not on a very large scale, it was sufficient to show me that accumulators could quite well be charged, when the electrical connections were properly made, by a dynamo driven at the irregular speed characteristic of a windmill. Sails I found were not a great success, especially since I had no way of reefing them. To prevent them being torn to pieces, the mill had to be stopped when the wind was high—that is, just at the time when it should have been going at its best.

I remedied this partially. I altered the wind-wheel from the English to the American type, having a number of arms and blades of sheet iron. I also introduced the further improvement of doing away with the driving wheel being always made to go in the same plane. This is absolutely necessary if the windmill is to drive a saw-mill, a corn-mill, or anything of that sort, but for electrical purposes the dynamo can quite easily be attached to the wind-shaft platform so as to turn with the mill as the wind changes. In this way all gearing is avoided, as the dynamo can be driven by ropes from a large wheel keyed directly on to the wind shaft. This I found to answer very well so long as the wind had a moderate speed, but, like all other windmills, I soon found that it had either to be made self reefing or stopped altogether when a breeze came. This is obviously very unsatisfactory, as the best of the wind for storage purposes is lost, and hence this problem presented itself—viz., how to construct a windmill that would satisfy the following requisites: (1) it must always be ready to go; (2) it must go without attendance for lengthened periods; (3) it must go through the wildest gale, and be able to take full advantage of it.

A possible solution of the problem is presented in the Robinson anemometer, which consists of four hemispherical cups attached to four arms, and moving in a horizontal

* Paper read before the British Association at Edinburgh.

plane about a vertical axis. From the theory of this instrument, which is, however, only approximate, it appears that whatever might be the speed of the wind, the speed of the cups attained a certain terminal value, such that the couple due to the wind pressure was exactly equal to that produced by the resistance to the motion through the air, and the friction on the bearings.

Last summer I erected a machine of this kind, which has been considerably improved within the past three months. The cups are replaced by semi cylindrical boxes attached to four strong arms, each about 26ft. long. The opening of each box is 10ft. by 6ft., and the vertical shaft is a long rod of iron 5in in diameter. At the lower end it carries a massive pit wheel, which actuates a train of gearing, and drives a flywheel 6ft. in diameter with the requisite speed for driving a dynamo connected with it by a belt in the ordinary way. This machine worked most satisfactorily, and with a fair wind speed gave about 2 e.h.p. I also tested it in a strong gale by allowing it to run with no load, and the result was perfectly satisfactory, as a safe terminal speed was attained, and all racing avoided. Hence I think that electrical windmills, at least for small installations, are likely to assume this form, as there is no limit to the size and strength with which they may be constructed, and, if necessary, several could be placed in any well exposed position, each having its own dynamo and set of accumulators. During the past few months I have increased the power of the machine by adding an auxiliary box to each arm with a gap between it and the previous one. This I find to be better than merely increasing the size of the previous box. As the whole is a case of vortex motion, the theory is very difficult. Information can only be got from models and applying the principle of dynamical similarity.

Regarding the electrical connections necessary I may say a word. All that is needed is that the circuit be broken when the dynamo is running at less than the storage speed. This is easily managed by a governor attached to the dynamo shaft, and which makes and breaks contact in a mercury pool at the required speeds. I have also tried a form of governor which throws a greater or less number of cells into the charging circuit as the wind varies, and in this way the machine is always doing some work.

We may next turn to the uses for which windmills are specially applicable. These are:

1. *For Lighting Lighthouses.*—These are always in exposed situations, where wind is plentiful, and often in such out of the way places that stores and coal for generating the electric light in any other way could only be sent with difficulty.

2. *For the Lighting of Private Country Mansions.*—Here, whatever form of power is used, accumulators must be provided. The wind, I think, specially recommends itself, from its cleanly nature, if it can be applied without the trouble of much attendance.

3. For factories so situated that a suitable mill could be placed on the roof, and thus be in an exposed situation.

In closing, I may just refer to the probability that the present system of electric lighting by incandescence will be superseded by some method of getting light from cold sources. When we think that 99 per cent. of the energy spent in a gas flame is waste, as far as light is concerned, that a percentage almost as high in the electric light is also waste, we are strongly tempted to think that lighting by incandescence cannot be a final form. Recent discoveries have distinctly proved that rapidly oscillating currents send out waves exactly similar to light-waves, but only having a much greater wave-length. Attempts have been made to get alternate current machines of such frequency as to send out such waves. Should these be successful, then light will be generated with much less expenditure of energy, and windmills even of very moderate power may be all that is required. I can quite easily fancy the time coming when each house has its own little windmill storing current which may be used to drive such machines as those alluded to, and giving a light suitable for the house. We should not require to drive large steam engines in order merely to let us see each other or read a newspaper.

Prizes.—The Société Industrielle de Mulhouse offers for award in 1893 several medals, amongst which are the following. A medal for treatise on factory lighting—choice of system; comparison between gas and electricity; cost, maintenance, power absorbed; hygienic conditions, fire risks, arrangement of buildings; advantages and the reverse of electric light in textile industries, spinning, weaving, printing, machinery; description of existing installations, results and defects. A silver medal will also be awarded for the application of electricity in any way to the printing industry. Papers must be sent before Feb. 15, 1893, to the President of the Societe Industrielle, at Mulhouse. Further particulars can be obtained of the secretary.

CONSULTING ENGINEERS FOR SMALL STATIONS.

There is an interesting paper by Mr. P. J. Salmon, of Galway, read before the North of Ireland Association of Gas Managers on August 9, given, with the discussion, in the *Gas World* last week. It was upon the necessity for a consulting engineer for small works—gas works, of course—and as the same necessity is present for small electric works even in a greater degree, and as this necessity will be greater as the number of main central stations increases, it may, perhaps, be well to refer more fully to this point. Mr. Salmon refers pathetically to the ignorant though well-intentioned interference of local committees, consisting of butchers, or grocers, and others, and relates his successful endeavours to raise the status of the various works in which he has been engaged into that of a respectable paying concern. His difficulties suggest the necessity of a consulting engineer to such works, both at the time of establishment and to uphold and supervise the efficiency. As every company, even with a good secretary and accountant, has its auditor, so should they have, he argues, their consulting engineer.

We need not enter into the question from the gas point of view—the gas managers are competent to discuss and settle the subject for themselves. From the electric lighting point of view, however, the problem is equally interesting and even more important, as the undertakings to which it may apply are not yet all started. One of the chief items of expenditure for the maintenance of an efficient central electric station is always that of the engineer-in-charge, who is responsible in all cases for the carrying on of the work, and in many cases for its actual erection. Now, a really competent electrical engineer is not and ought not to be a cheap man, and an item of three, four, or five hundred a year added to the expense of running a small central plant is a serious addition, and one often enough done away with. Nor is it likely that in a plant such as we are imagining—say of some five thousand lights or so—that the full attention of such a man would be occupied. The necessity, therefore, seems obvious for the introduction of a central station consulting engineer, who shall be called in, as the auditor is called in, to make quarterly inspection, analyse the accounts, and impartially report upon the progress and efficiency of the plant. His necessity is acknowledged theoretically at the time of the erection of the central station, but in many cases that could be named in the past his services have been dispensed with in the beginning, just that time when they would have been most valuable, and are only called in afterwards when the most he could do was to suggest modifications. The circumstances of each district are so diverse, and the necessity for careful choice so evident, that the wonder is that business men should ever have been led to institute erection of plant at considerable expenditure without careful discussion of every point of detail. Yet cases are by no means uncommon of the choice haphazard of, say, a high-tension system, or triple-expansion engines, or a certain type of

boilers, simply from imitation or a vague idea or assurance by the makers that they were the best, rather than from a sure knowledge that they were the best suited to these particular requirements. And it may well be that high-tension, triple-expansion, and complicated boilers, good in their way in large works, may, both on account of cost and absence of suitability, run away with that margin of profit which a properly thought-out system might have produced. Then, again, there are two matters which it is pre-eminently the function of a good consulting engineer to study—namely, economy of maintenance and facility for extension. Economy of maintenance does not mean alone proper choice of the system of production and distribution, but also the most careful consideration of the arrangement of the station, water heaters, steam economisers, mechanical stokers, condensing apparatus, and so forth; and the manager of a firm of electrical engineers who may be admirably suited for installing engines, dynamos, and mains, is not necessarily capable of arranging all these matters to the utmost satisfaction. Nor is the question of future extension always fully considered. The consideration of these matters, however, is the duty of the consulting engineer, and his fee in most cases is the most economical expenditure of the whole cost. As regards maintenance, again, for a comparatively small sum the station, otherwise overcharged with the salary of an experienced engineer, might be supervised in conjunction with several others, with all the advantage of the best advice and experience, and without the cost of paying the whole charge for such expert knowledge. When the fight is so keen between methods of illumination, when every attention is being turned to efficiency and cheapness of generation of current in the large towns, there should yet be the same possibility of efficiency, and even greater possibility of comparative cheapness, with the moderate-sized installations of our smaller towns, if arranged and supervised with the aid of the central station consulting engineer.

INSTITUTION OF CIVIL ENGINEERS.

The list of suggested papers for reading before this institution has just been issued, and the plan of suggesting papers might well be followed by kindred institutions. The electrical engineers have an institution, and it is a great pity that there exists so much jealousy within its borders. Successful societies, like successful companies, are successful because of the predominating influence of one or two master minds. It is so with the Civil Engineers, but not so with the Electrical Engineers, though the latter has, in a certain sense, been somewhat successful of late years. Its numbers have increased, its balance-sheet is respectable; but its influence is not to be compared with that of the parent institution. It cannot command the best papers. It hardly dare say, "Papers which have been read at the meetings of other societies or have been published cannot be accepted by this Institution." The fact is that "paste and scissors" and second-hand papers are admitted. Discussions are mainly within a ring fence, and new blood is not always welcome. Pushing business men make its boards part of the shop, and much of its proceedings has become to be looked upon as "merely a matter of business."

But to return to the suggested papers of the Civil Engineers, we find that the list contains between fifty and sixty different subjects upon which the institution desires information. Of course, this does not mean that the institution restricts itself to the accepting of papers upon these particular subjects, but the list is given as an aid to those who desire to prepare papers. That electrical engineering is taking a high place in general engineering work, may be seen from the fact that the list contains not less than nine or ten subjects in that branch of the profession. The suggested subjects are:

The cost of working electrical tramways, taking account of interest on capital, and of a sinking fund for depreciation.

The most suitable form of electric light mains, having regard to durability, economy of conducting material, and facility for making and laying house connections.

The risks of electric lighting to life and property, with the means to be taken to prevent or lessen them.

The best arrangement of engine for any given electric light station.

Electrical motors for (*a*) inland navigation, (*b*) ocean vessels.

The electro-deposition of copper.

On the application of water power and its transmission to a distance by electricity.

The design of electric locomotives.

The practical working of multiphase alternating-current motors.

In our opinion, the Institution of Electrical Engineers might well make out as lengthy a list of suitable subjects for paper to be read before it. Why, for example, should the Civil Engineers obtain interesting information as to electrical tramways, or to electric light mains, or to any of these other suggested subjects? We are quite sure, however, that, as at present constituted, a good deal of energy is wasted in fruitless directions; the younger members of the Institution of Electrical Engineers not having sufficient guidance, nor perhaps have they sufficient incentive to prepare papers. We are among those who contend that if a learned society can make its income and expenditure meet, it ought not to save up money—hence the Institution might well spend some of its surplus funds in subsidising the members who will prepare the best papers.

NOTE ON SOME EXPERIMENTS WITH ALTERNATING CURRENTS.*

BY DR. LOUIS DUNCAN,

Assisted by Mr. E. R. Carichoff and Messrs. R. H. and G. E. Hutton.

I must apologise for the brevity and scope of this paper, not because I sympathise with long papers, but because I had intended to embody in this the results of a considerable

* Paper read before the American Institute of Electrical Engineers.

amount of work done during the year, and I find that the rush of work at the last of our term has made it impossible for me to do more than write a note descriptive of the methods used, and to give a few illustrations of its use. Last fall I published a preliminary statement of a method for obtaining alternating-current curves, and it has proved so satisfactory that we have used it in a number of investigations of alternating-current phenomena.

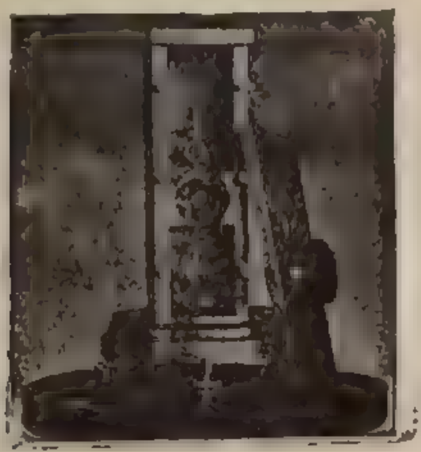

Fig. 1.—Dynamometer.

The first real representation of an alternating-current curve was made by Joubert, who employed a contact piece rotating with the armature of a dynamo, touching a fixed brush at a point of the revolution determined by the position of the brush with relation to the dynamo poles. He obtained a curve for current which was approximately a sine curve. Later, in 1888, Messrs. Wilkes, Hutchinson, and myself modified the method to obtain the curves for E.M.F. and current in the primaries and secondaries of induction coils. This modification was used afterward at Cornell, where Prof. Ryan and others made valuable experiments, and it has been more or less generally employed. The principal difficulties lie in the fact that with

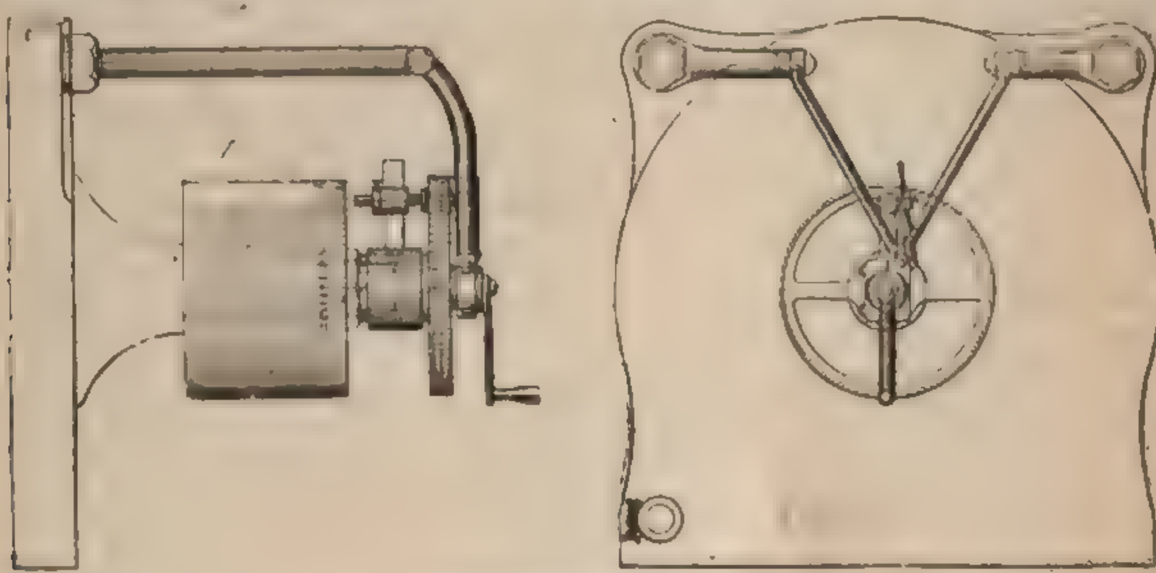

Fig. 2.—Contact Arrangement.

a single commutating arrangement but one curve can be taken at a time, and as an experiment involving four curves takes something like 45 minutes, the condition may seriously change, while the whole voltage of the dynamo is at times on the commutator. It is at best rather a tedious method. In our work referred to above, and in the work at Cornell, E.M.F.'s were measured by an electrometer, and currents were obtained by getting potential differences at the terminals of a non-inductive resistance through which the current passed. Lately, in France, two commutating arrangements have been used to give two curves at once, with a condenser charged through the contact and discharged through a d'Arsonval galvanometer.

By the method which I described last fall, any number of curves may be obtained simultaneously, with only a few volts on the commutator and with a rapidity and accuracy much greater than by the other methods. Briefly, a number of dynamometers are used, equal to the number of simultaneous curves to be obtained. These dynamometers are very cheap and convenient. The first ones used were made by Mr. Carichoff and myself, and were quite satis-

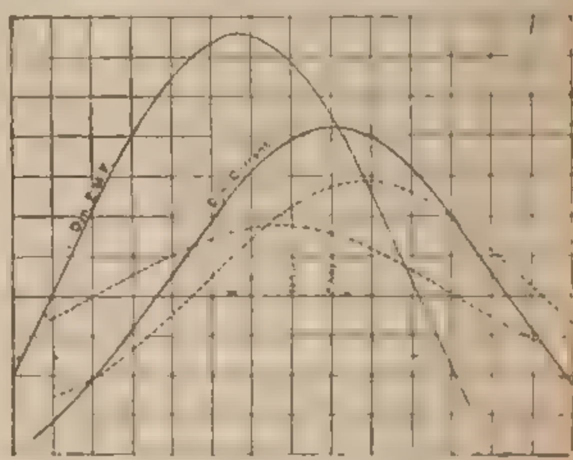

Fig. 3.—Tesla Fan Motor—Period $\frac{1}{140}$.

factory; but experience having suggested some improvement, and our time being fully occupied, Messrs. E. S. Ritchie and Sons made four of them, such as are shown in the picture, Fig. 1. I will describe them more minutely below.

The four dynamometers have their stationary coils wound for, say, primary current, primary E.M.F., secondary current and secondary E.M.F. The movable coils are wound with fine wire, and are all connected in series. The E.M.F. instruments are made exceedingly sensitive, so their self-induction may be made a minimum, and in series with them is placed a large non-inductive resistance, the relation of the self-induction and resistance being made such that the former may be neglected. The circuit of the movable coils is through a battery of a few storage cells to a brush, which may be moved by hand through the arc of a circle, and which touches a contact piece on the dynamo shaft once every revolution. The other end of the circuit being joined by a sliding connection with the contact piece, the circuit is closed through the cells and coils for a short period once every revolution. The instant of closing this circuit is determined by the position of the movable brush with respect to the dynamo poles. Now suppose an alternating current is sent through the stationary coil of one of the dynamometers. If an instantaneous current be sent through the movable coil,

an impulse will be given it dependent on the value of its current and on the instantaneous value of the current in the stationary coil. As the period of the coil is great compared with the period of the dynamo, we will get a steady deflection dependent on this product. If now we move our contact brush, the instantaneous current will pass at some other point on the alternating-current wave, and our deflection will be proportional to the value of the current at this point. By moving the brush through an angle corresponding to a complete wave we can plot the wave exactly, providing we have properly calibrated our dynamometer.

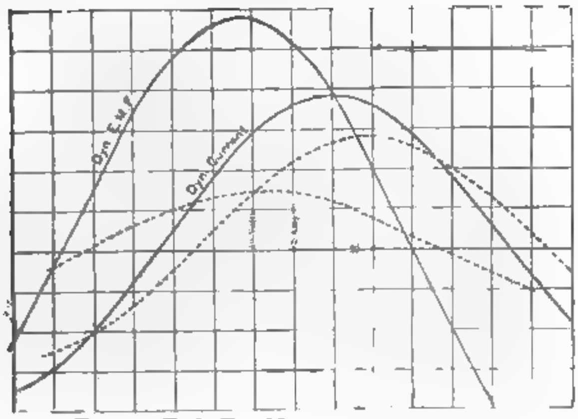

FIG. 4.—Tesla Fan Motor, held—Period $\frac{1}{133}$.

It is apparent that in order to attain accuracy, our instantaneous current must be very brief and very steady, and its value must be the same in actual work as in calibrating. A d'Arsonval galvanometer in the circuit allows us to judge the two last points, and we found that when a high resistance was used in the circuit, so that any variation in the contact resistance was eliminated, almost absolute steadiness was obtained. It was also assured by using a condenser charged during part of the revolution and then discharged by the contact brush through the circuit. To give an idea of the current in this circuit, an ordinary arrangement, when the condenser was not used, was 12 volts through 1,000 ohms, and it must be remembered that this current only passes an exceedingly small part of the time.

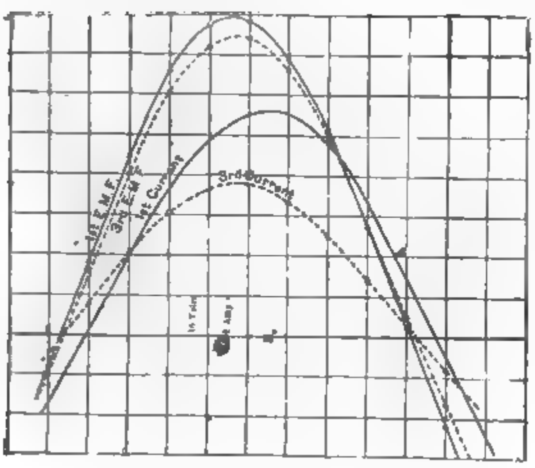

FIG. 5.

Dynamometers.—The dynamometers were made of wood mounted on a revolving base, so they could be adjusted with respect to the meridan. It will be seen on looking at the picture, Fig. 1, that one side is made removable to facilitate adjustments. The fixed-coils are wound in two cylinders, which move in and out through holes in the sides, and whose distance apart is adjusted when the instrument is calibrated, so the scale divisions read directly in volts or amperes, or fractions of them. The movable coil is suspended by a silk fibre, which gives it no directive force, but which sustains it. Directive force is given the coil, and current is introduced to it through two palladium hair springs, which are fastened to stiff brass wires, which serve as the axis of the coil. A vane in a beaker filled with glycerine damps the swinging and makes the instrument absolutely aperiodic. I have rarely used instruments which give more satisfactory results—the zero is invariable, readings may be taken with great ease and rapidity, while a reversal of the current gives equal readings on the two sides of the zero. To show the rapidity of the readings, six curves, representing different quantities in a step-up-and-down transmission were taken in a little over five minutes, and in this case two instruments were used for four curves—those at the sending and receiving ends of the plant—and, therefore, had to be switched from one side to the other at every reading. Twenty points were usually taken for each wave. The curves could, of course, be

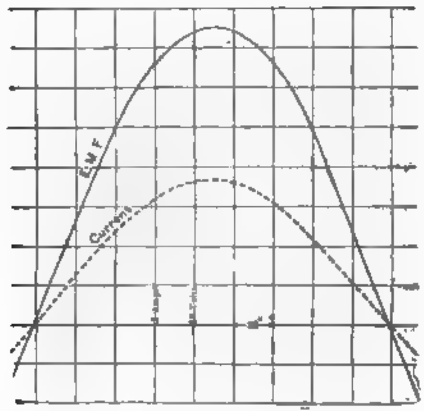

FIG. 6.—Dynamo Direct on Lamps.

photographed instead of observed, but the latter is so much simpler and more satisfactory that—especially in a laboratory where there are plenty of observers—I much prefer it.

Contact Arrangement.—This is shown in Fig. 2. As it comes outside the belt, and as it was often necessary to remove the latter, the swinging arrangement shown was designed and constructed by the Messrs. Hutton. On the shaft was a hard rubber cylinder, with the brass contact almost flush with its surface. The whole arrangement worked admirably. The results of our work will have to be another story. I will simply give a few to illustrate the method.

We have a small Tesla fan motor, intended to work on an ordinary incandescent circuit. There are eight poles, the alternate ones having their windings in different circuits, one set of poles having a few turns of coarse wire, the others having a greater number of fine wire turns. The curves in Fig. 3 show the condition of affairs when the

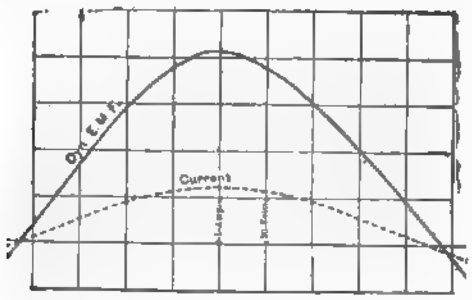

FIG. 7.—Copper Condenser with Coils. Cap. 1·35 M.F's. Wire Core.

motor was working; in Fig. 4, where the armature was held. In the same case, the energy represented corresponds, of course, only to the losses. It seems to be the general impression, by the way, that a rotating field motor starts up with the same torque as a corresponding continuous-current machine. I have shown, however, that a two-phase motor corresponds exactly to a converter—or rather two converters—in which the secondary has an outside resistance of $\frac{p^1}{p - p^1}$, where p^1 is the angular velocity of the armature and p that of the field. When p^1 is 0—that is, when the motor is at rest—it will be seen that the current is in the worst possible condition for starting, and the torque for a given current is small. It is like starting a continuous-current motor with the brushes almost 90deg. from the proper position.

But most of our work has been with circuits in which both self-induction and capacity have been introduced. It is a well-known fact that circuits carrying alternating currents may be given the same period of vibration as the current, or, to put it another way, circuits may be so arranged that with currents of a given period the sum of the energies stored up in the circuit and given out by it is zero. With a condenser and self-induction properly adjusted, if

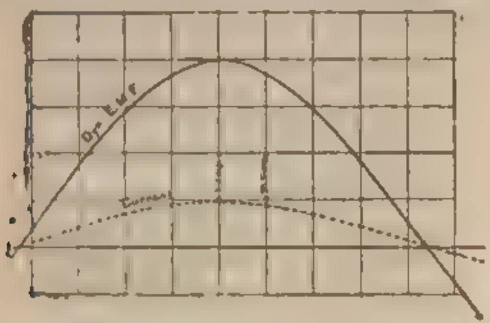

FIG. 8.—Tinfoil Condenser with Coils. Cap. 1·33 M.F.'s. Wire Cores.

energy from the current is being stored up in the condenser, an equal quantity is being given to the current by virtue of the self-induction. That is, we can neutralise our self-induction by a capacity. I can hardly think of any fact more likely to play an important part in the future of alternating-current work. For instance, if a circuit has in it a periodic current consisting of a number of sine curves of different periods—one-third, one-fifth, one-

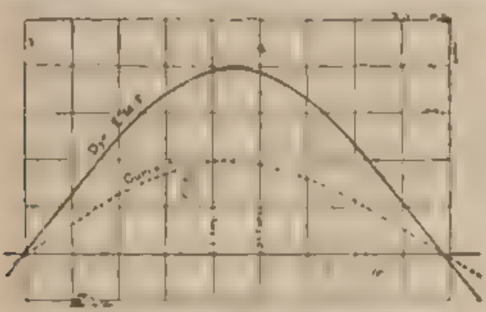

FIG. 9.—Tinfoil in Parallel with Copper. Condenser with Coils. Cap. 2,675 M F.'s. Wire Core.

seventh, etc., the period of the fundamental wave; then if we put in inductive relation to this circuit another circuit whose period is, say, one-third that of the fundamental wave, this current will pick out the one-third period waves in the primary.

An ordinary sine curve E.M.F. may be made to give a periodic current wave with these higher harmonics in several ways—by having in the circuit a self-induction coil whose iron core is saturated when the current nears a maximum, or by using the same coil with a capacity which

FIG. 10.—Tinfoil in Parallel with Copper Condenser with Coils.

neutralises one of the values of the varying self-induction; so we can produce these higher harmonics, and we can pick them out. But it is a complex subject not to be treated here. In all such experiments, however, there are several points which must be carefully attended to, or there will be very unsatisfactory results. If the iron core of the induction coil—provided such a core is used—is not properly laminated and annealed, or if there are considerable losses in the condenser the results will be disappointing. Take the case, for example, where there are eddy currents in the core and there is loss in the condenser. The first effect corresponds to a short-circuited secondary near the coil; the loss in the dielectric of the condenser means that energy is taken from the current, and this energy must be represented by the product of the current into the E.M.F., e corresponding to a transfer of energy, or it is $e\,i$. The

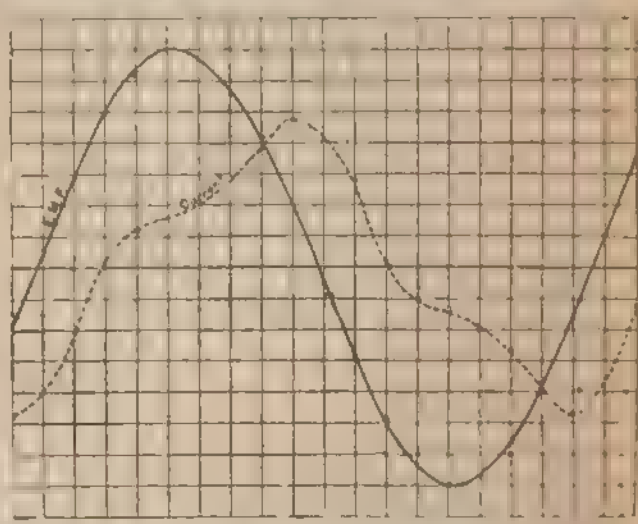

FIG. 11.—Siemens Dynamo on Transformer. Secondary Open Curves taken with Experimental Dynamometers.

value of e is a maximum when the displacement is greatest—that is, when the current is greatest—and for a given current and dielectric varies as $\frac{1}{c}$. If we represent these effects by a revolving diagram as is ordinarily done, and suppose we have neutralised the self-induction by a capacity, we get something like the figure, Fig. 12. The result is that relation between R I and E instead of being 1 to 1, as would be the case were there no disturbing causes, is 1 to 1 +. That is, for a given E.M.F. the current is less than it should be, and a glance at the figure will show that it is thrown ahead of the E.M.F. No possible change in our self-induction and capacity can remedy this decrease in the current, although we may, of course, make the phase angle zero if we wish.

An excellent way to make an iron core, by the way, is to shellac fine, well annealed wires, spread them along a

FIG. 12.

piece of thin paper, brush them over with shellac and then roll the mat so formed into a cylinder. The losses in a condenser are usually small. They are discussed in a paper of Messrs. Hutin and Leblanc, published last spring in *La Lumière Electrique*. We find, however, that if the condenser is made of very thin tinfoil and has a large area, then for heavy currents it may considerably decrease in capacity and offer a definite resistance to the current.

The curves given have been selected almost at random from a mass of data. We have not the time to discuss the results, which are hardly within the scope of this paper. Fig. 5 gives the curves at the two ends of a transmission plant where the voltage was raised from 50 to 1,000 volts and reduced again. Fig. 6 gives the curves for the dynamo directly on the same lamps. It is seen that the transmission decreases the E.M.F. and current, and increases the lag of the dynamo current.

Figs 7, 8, 9, and 10 give curves taken from the dynamo circuit when self induction and capacities were inserted. In Fig. 7 the core of the induction coil was only fairly well laminated; and a condenser with copper sheets between paraffined paper was used. The maximum current is a little over 1·2 amperes, while it should have been about four amperes if there were no losses in the circuit. The second point of crossing is thrown out by a change of speed of the dynamo. Fig 8 shows the result of substituting a tinfoil condenser of the same capacity in place of the copper one. In Fig. 9 both condensers were used and a considerable part of the wire core was withdrawn. In Fig. 10, with the same two condensers, a solid iron bar was used as the core of the induction coil.

Fig. 11 gives the curves obtained in the circuit of a dynamo connected to a transformer whose secondary circuit was open.

ANTI-FRICTION MATERIALS FOR BEARINGS USED WITHOUT LUBRICANTS.*

BY KILLINGWORTH HEDGES, M.I.C.E.

The use of oil as a lubricant in machines is to separate the rubbing parts and to diminish the friction of metal upon metal by an intervening film of the lubricant.

If the oil is supplied in sufficient quantity to cause the entire separation of the metals, the friction may be reduced to a measure of the viscidity of the unguent used; where oil is furnished in less quantity, then the friction of metal upon metal is usually resistance due to interlocking particles of the revolving and stationary parts, the oil used under this condition finding its way from the bearing loaded with the metal that is gradually torn from either the revolving shaft or the bearing in which it has worked. It is a well-known fact that heavy lubricants effect a better separation of the metals than those that are more limpid, although the power required to slide the surfaces one upon the other is much less with the latter than with the former, but at the same time the wear and tear of the metal may be greater. It has been stated by more than one authority that it makes little difference what metal is used for the bearing of a revolving shaft provided oil in sufficient quantity can be introduced, so as to separate the shaft from the bearing in which it revolves; this is proved by the success which attends the use of cast iron for the bearings of ordinary shafting, it being no unusual occurrence to find the cast-iron sleeve of an adjustable hanger showing the tool marks after running several years with an excess of lubrication. Such a bearing would, however, quickly seize if the oiling was neglected, and therefore the friction may be said to vary according to the attention paid to the oiling. For very low pressures, amounting to only a few pounds on the square inch on the rubbing surfaces, oil causes a loss of power, so to make it advisable wherever possible to dispense with it altogether; Prof Coleman Sellers even goes further than this and states that even when the pressure on the rubbing surfaces is less than 50lb. per square inch, the viscidity of the unguent acts as a sensible retardent.

Engineers have for a long time been looking for a material capable of being used for bearing surfaces, and having a low coefficient of friction when worked dry and without any oil. The idea is not one of recent date only, but may be said to go back to the time of the Romans, as some of the hand flour mills found at Pompeii have the lower stone fitted with an iron bearing which evidently worked dry in the stone socket of the upper stone. The celebrated Coulomb experimented with an iron axle moving in a bush of elm: the friction was stated to be "one-twentieth of the force of pressure;" he also made numerous experiments with wood axles slightly smeared with tallow, and also recommended the use of blacklead; the material he found to give the best results was green oak on elm, and I believe the wooden axles of the waggons which are used in Derbyshire at the present time to transport the heavy grindstones from the quarries, are constructed with axles of oak in a similar manner; throughout Egypt, in the Nubian waterwheels, which are everywhere employed for irrigation, unlubricated wooden bearings are used, which appear to wear very slowly, the surface of the bearing acquiring a fine glaze. Stone bearings have also been employed for shafts; according to Rankine, the natural stones fit for this purpose are those which are wholly free from grittiness, and are somewhat inferior in hardness to iron, such as gypsum, pure clay slate, compact limestone, marble, and silicate of magnesia; from the latter the substance called "adamas" was made by calcining the magnesia, grinding and moulding it by hydraulic pressure into blocks, which were then baked.

In addition to these oilless bearings there are others in which perhaps a small quantity of grease might have been employed, such as the leather bushes used in spinning wheels, and which we are familiar with on that part of the oar which works in the rowlock. Glass has also been tried, but the only kind which has survived to the present and has been the most successful of all is the plumbago bearing. The author has been told by the old millwrights that this material was often used as the footstep bearing of the upright shafts in water mills, and most of us have seen plumbago employed instead of tallow for lubricating wooden bearings, and there is the familiar example of the carpenter's screw. The first adaption of plumbago in a more practical form was the invention of Gordon, who inserted a number of moulded plumbago plugs in the standard size axle-box of an ordinary carriage wheel. It is said that the vehicles ran successfully without any lubricant.

Graphite or plumbago is the principal ingredient in numerous inventions for dry bearings, many of which have not got further than the Patent Office; it has been mixed with pulverised iron, asbestos, vegetable fibre, paper pulp, blood, and in one curious adaption sponge is used. In nearly all these applications the anti-friction composition is packed into suitable grooves, which are used in the bearing, very much in the same way as asbestos is used in cocks. A substance which has been termed "metalline," which, although it contains graphite, appears to be composed of finely-divided lead, has been rather extensively employed. The chief disadvantages were the expense due to the way the material was used in the form of little plugs let into drilled holes, and the necessity for oiling when the plugs were worn sufficiently to cause contact between the metallic surfaces, thereby changing the character of the bearing.

The latest form of dry bearing is of solid material, which can either be moulded so as to fit any plumber's block, or can be tooled or worked in the same manner as an ordinary brass. A new material for this kind of bearing has been recently tried in the United States, and consists of finely-ground plumbago, mixed with wood fibre in a moist condition, and pressed into a mould of proper form; it is then saturated with some drying oil, and oxidised in hot dry air. This bearing has been favourably reported on by the committee of the Franklin Institute, and a shop has been fitted up complete, so that the whole of the machinery, including the steam engine, runs without any lubrication at all. The report, which may be taken to apply to dry bearings generally, states "that an invention of this kind, by diminishing the use of lubricants, diminishes the cost of machine construction, by doing away with the many devices incident to oil—oil cups, oil-hole covers, the oil-holes themselves, which have to be carefully placed, oil tubes to lead the lubricants to the inaccessible parts of machinery, as well as the cost of the personal attention and the cost of the lubricant required to keep the machinery in perfect order."

My own investigations of a suitable material for an oilless bearing began with the use of plumbago, which was moulded so as to form a circular bush, but this was soon discovered to be a failure on account of its rapid wear. I then constructed bearings of ordinary carbon, such as is

* Paper read before the British Association at Edinburgh.

used in batteries, and for producing the electric light by means of the voltaic arc. The first experiment was made with the bearings of a small dynamo, which ran for a considerable time, but the drawback of using carbon was mainly on account of the impurities which it often contained. A small amount of silica in the carbon was found to cut the shaft very badly, whilst if soft carbon was used the wear was as rapid as with plumbago. In order to lessen the cutting action and the friction, finely powdered steatite was mixed with the carbon, and henceforth no difficulty was experienced, even when the load was unequally distributed on the bearing. The name of carboid has been given to this mixture, its specific gravity being 1·66, that of carbon, as used in arc lamps, being about 1·68; therefore carboid is about one-fifth the weight of brass, it can be moulded with the same ease as carbon, and can be turned, bored, or shaped to any desired form. In practice it is found that the cylinders, as they leave the dies, are quite true enough to be put into bearings without any tooling, although it is preferable to run for a short time with half the load, and then remove and scrape the bearing so as to equalise the surface of contact.

Friction as compared with Lubricated Bearings.

Prof. Sellers, writing on the Franklin Institute report, states that "the coefficient of friction is lower with the dry bearings experimented on than that of many oiled bearings in good condition, and that it is undoubtedly lower than with metal bearings, as usually operated with moderate attention and poor qualities of oil. It seems to be constant in its frictional resistance, whether warm or cold, while it does not run lighter when worn by use, as some oiled bearings do. Its uniform action is better than many oiled bearings and very much safer; the constant amount of frictional resistance being known, can be provided for in the power of the machine."

The above agrees in the main with Prof. Unwin's experimental results with carboid. A bearing, 1¼in diameter by 2½in. long, cut in halves, was recently tested under loads varying from 100lb. to 1,800lb., or about 15lb. to 170lb. on the square inch, at speeds from 110 to 490 revolutions per minute, the period of test extending over six days, during which it was kept almost constantly running without any lubrication or attention.

Summarising the experiments, it appears: 1. That the coefficient of friction is almost the same, and has not diminished as the carboid became worn to a better bearing surface. 2. That the coefficient of friction increased as the temperature increased during the run, but is practically the same for any increase of pressure, and diminished with increase of speed, the maximum number of revolutions per minute being 490. 3. That no injury is caused to the shaft even if the bearing gets very hot, as it was found to be impossible to make it seize.

The trials were made in one of Prof. R. H. Smith's new design of testing machine, in which there is no bending pressure upon the journal at all, the load being adjusted by the compression of a spiral spring, which presses upon both halves of the bearing with equal force. The heat generated by this form of machine is twice as much as that in which the load is applied to one step only, and this to a certain extent limited the pressure to which the bearing was subjected, and the experiments with greater pressures will have to be completed with another design of holder, so arranged that the heat generated has a better means of escape.

The conclusion arrived at by the author with regard to dry bearings is that the conductivity of the shaft and the holder or support of the bearing; if this was arranged that any heat generated is dispersed, the coefficient of friction will not exceed that of a lubricated bearing.

First Costs.—If the bearing works under such conditions that any heat generated at starting a new bearing may readily be conducted away, the first cost of a dry bearing will be less than any form of brass, but taking the case of a dynamo bearing where any excess heat might be disadvantageous, it will be necessary to carefully true the bearing by scraping so as to fit the shaft, and under certain conditions where there is a great pull on the belt, it may be necessary to keep the bearing cool by means of a circulating flow of water.

Economy of Working.—This is very marked; besides the cost of the lubricants used in large establishments, there is also the attention required to apply the oil and keep the parts clean. In laundries and in other trades where unskilled labour is employed, the danger of oiling machinery in motion is very great; besides this there are instances where the lubricant used is in itself a source of danger, such as the risk of oil waste taking fire by spontaneous combustion, and the drip from bearings certainly renders the floors of mills highly inflammable.

The principal application of carboid up to the present time has been for the bearings of ordinary shafting, and for bushing loose pulleys; it has also been applied for the bearings of steam-heated rolls such as are used in cloth mills and paper works. The result of two years' experience and many experiments with light trucks seems to point out the desirability of extending its use to the axle boxes of tramcars, and perhaps railways generally, as it involves no change in the axle-boxes; even the existing brass can remain and be faced with carboid, which material can be cemented to either a smooth or rough surface.

Exhibits.

The bearing used in Prof. Unwin's experiments after six days' running.

Carboid blocks similar to those used for the wire-rope tramways in Edinburgh.

Two-inch carboid bush taken from shaft after a year's constant use.

ON THE CLARK CELL.*

BY DR. KAHLE.

In connection with the report of Prof. Glazebrook, I beg to call your attention to some researches I made, by order of the Physico-Technic Institute at Berlin, on Clark cells. The time is too short for communicating my measuring methods and results in full extent; I can only give you a short summary of the chief points.

I used in my researches Lord Rayleigh's H form, the positive electrode being mercury once distilled, the negative an amalgam containing 90 parts of mercury and 10 parts of zinc. The last was filled in the vessel as a hot liquid, and solidified on the bottom. The paste, which covers the positive electrode, is made by grinding together mercurous sulphate, mercury, and a mixture of crystals and concentrated solution of zinc sulphate. No heat was used in preparing this paste. The mercurous sulphate was bought, and contained, according to chemical analysis, no foreign ingredients. The zinc sulphate was made basic by boiling with rods of metallic zinc; after cooling, the dissolved oxide of zinc precipitates, and with it the oxides of the metals more negative than zinc. For oxidising the ferrous sulphate, which is always present in commercial zinc sulphate, a small current was sent between two platinum electrodes through the boiling basic solution; the ferrous sulphate was changed by the generated oxygen into ferric oxide, and fell out. The H cells set up with these materials showed a great agreement in their E.M.F.'s, I never found a difference greater than $\frac{1}{10000}$th of a volt between the E.M.F. of any two of them.

The next point I studied was the influence of the impurities in the different materials composing the cell on the E.M.F., because on the one side it is well known that the smallest impurity of the mercury alters very distinctly the E.M.F., and on the other side the mercurous sulphate I bought never contained impurities of a remarkable amount, and different samples always had the same qualities; I only investigated, as the most important matter, the impurities of the zinc and its sulphate. It was found that the foreign ingredients of the zinc sulphate are of very little importance, and that only the presence of free acid in the above described cleaning process, the result of boiling with metallic zinc, alters the E.M.F. in a considerable degree. Among the impurities of the zinc only those caused by metals more positive than zinc are of importance; the zinc may contain considerable quantities of the negative metals without any alteration of the E.M.F. I suppose the impurities of the zinc are of greater importance. If we use

* Paper read before the British Association at Edinburgh.

it in the form of rods amalgamated on the surface, it seems to be a great advantage to dissolve the zinc in mercury, using it then as a solid amalgam.

The following are the values I found by a great deal of observations for the temperature coefficient of different forms of cells, measuring between 10deg. and 30deg. in rising and decreasing temperature. The figures here given are the mean values of some cells of the same form, treated in the same manner.

Form of the cell.	Temperature coefficient.	Mean difference between calculated and observed values of E.M.F.	Mean difference between the E.M.F. of the different cells and that of the mean of several H cells used as standards.
		The unit being $\frac{1}{10000}$ths of a volt.	
H cell set up in Lord Rayleigh's manner.	+0·000812+0·000013 (+ − 15)	12	+ 3
H cell, the paste covering both electrodes.	+0·000774+0·000020 (+ − 15)	12	+ 7
A new form for researching purposes, the paste covering both electrodes.	+0·000791+0·000017 (+ − 15)	9	+ 9
The cell issued hitherto by the German Reichsanstalt.	−0·000806+0·000006 (+ − 15)	30	− 29

The mean value of the temperature coefficient, therefore, would be

0·000796+0·000014 (+ − 15).

Lord Rayleigh has given the following values for the two different cells he investigated:

+0·000827+0·000018 (+ − 15)
+0·000740+0·000016 (+ − 15)

the mean being

+0·000783+0·000017 (+ − 15).

I suppose, for practical purposes, the value found by Lord Rayleigh and by me are identical.

The most important matter is to obtain the absolute term of the E.M.F. For the purpose I used a measuring arrangement similar to Lord Rayleigh's. The current, which produces on the terminals of a known resistance a pressure equal to that of the Clark cell, was obtained by the silver voltameter. It was found that the same current deposits the more silver the more oxide of silver is dissolved in the solution of the nitrate. I made a solution of nitrate crystals, and boiled a part of it a long time with oxide of silver; the deposit gained with this basic solution was about $\frac{5}{10000}$ths greater than that with the original solution. Therefore, using a certain number for the equivalent of silver, there will be a little uncertainty of some parts of 10,000 in measuring currents by the deposit of silver. Now, as first shown by Prof. Schuster, and also proved by me by a good deal of experiments, the deposit, when the voltameter is in vacuo, is about four parts of 10,000 greater than in ordinary air. But the absolute value of the E.M.F. is not touched by this fact, because making the electrolysis in this manner one has certainly to take a greater figure for the equivalent, and therefore the ratio between the unit and the measured amount of current remains the same. The following figures are given by taking one ohm = 1·063 S.U., and by assuming that a current of one ampere strength deposits in an hour 4·0259 amperes; the last figure exceeds that given by the Board of Trade only by six parts of 100,000. I found by some 30 experiments, the E.M.F. of the H-cells, set up with clean materials in the above-described manner, as 1·4332 volts at 15deg., and am sure that, when using the same arrangement of the silver voltameter, this value will be right by five parts in 10,000 if the equivalent is sure in this limit. If I express the value given by Lord Rayleigh for the cells of the original Clark's form in this unit, it is 1·4346 volts at 15deg. Lord Rayleigh finds the E.M.F. of this H cell a few ten thousandths of a volt greater than that of the old form. Therefore it would, perhaps, be 1·4350 volts at 15deg.

Recently, Prof. Glazebrook has made a new determination, and finds in the above fixed units as E.M.F. of the original Clark cell, 1·4312 volts at 15deg. He has also compared H cells set up by me and now brought to England, and finds their E.M.F. by $\frac{4}{10000}$ths of a volt smaller than that of the original form. Therefore, the E.M.F. of the H-cell is 1·4338 volts at 15deg. This last value and that found by me are in good agreement. It is remarkable that the anodes and cathodes in my voltameters are much smaller than those in the English ones.

It may be mentioned here that the mean E.M.F. of four H cells set up in the same manner as before, but containing, in accord with Prof. Carhart's directions, a solution of sulphate of zinc, saturated at 0deg., was found as 1·442 volts at 15deg., using the same units as above.

It only remains to give some directions on the best form of Clark cells. I suppose it will be good to distinguish such cells which shall remain as standards in the laboratories and are used by their manufacturer, and such ones which shall be used for practical purposes. These do not need to have the same degree of accuracy, but they must be able to be carried about. In the Board of Trade's memorandum, the original Clark cell is adopted as the standard, but I suppose Lord Rayleigh's H-form gives more accuracy and is easier to set up. In the old form, not all the parts of the zinc rod are in saturated solution, and therefore the value of the E.M.F. will be a little uncertain. Another disadvantage is, that parts of the zinc rod may fall down in the mercury, and will so produce a considerable changement of the E.M.F. On the other hand, the electrodes of the H-form are always in concentrated solution, and there is no possibility of parts of the negative electrode coming over to the positive one. I have set up about 60 H-cells, and have found no difficulty, when using carefully cleaned materials, to keep the difference of the E.M.F. of the single cells under a ten thousandth of a volt.

To construct cells for practical purposes which will stand carriage, the most simple way is to separate the two electrodes by a porous wall. I can show here such a cell of a form constructed by Dr. Feussner and issued hitherto by the German Reichsanstalt. The positive electrode is an amalgamated platinum plate with the surrounding paste in a porous vessel of clay. The zinc rod forming the positive electrode is on the upper part protected by a glass tube; the lower part is blown rectangularly and covered with crystals of sulphate of zinc. The whole glass vessel is filled with a concentrated solution of this salt. The E.M.F. of such cells is about $\frac{3}{10000}$ths of a volt higher than that of the H-cells. The agreement of different cells of this form is very sufficient for practical purposes; the difference between the E.M.F. is always smaller than $\frac{1}{1000}$th of a volt. The only disadvantage of this form is, that its E.M.F. does not follow quickly the alterations of temperature; but I suppose one could improve that by diminishing the size of the cell.

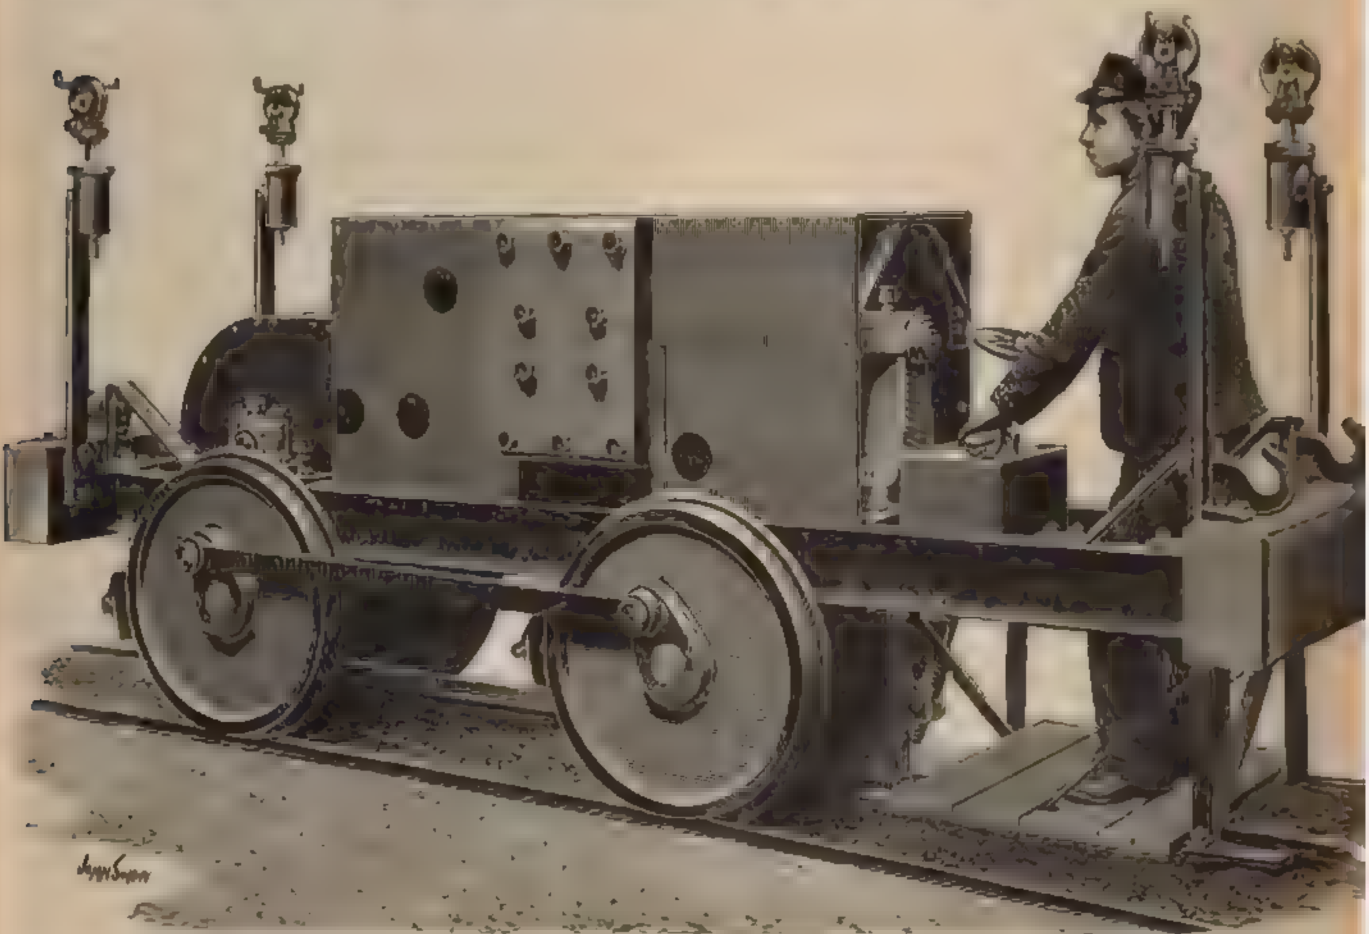
We endeavoured in the Reichsanstalt to get transportable Lord Rayleigh's H form on account of its good qualities, and to do this without introducing foreign substances as porous walls. The investigations in this direction are not yet finished, but I can show you here a cell which was constructed for this purpose and seems to be good. The positive electrode is formed by an amalgamated platinum plate fixed on a wire of the same metal, which is melted in the bottom of one of the two tubes forming the vessel. The negative electrode is formed by the 10 percentage zinc amalgam solidified on the bottom of the other tube, and also connected with a platinum wire melted in the glass. The whole vessel is filled with the paste and closed by a glass stopper perforated by a thermometer, of which the bulb is within the vessel. Such a cell can be turned

without any danger and is suitable for transport. The E.M.F. is about $\frac{1}{10000}$th of a volt smaller than that of the H cells; the agreement between the E.M.F.'s of different cells constructed in similar manner does not exceed $\frac{5}{10000}$ths of a volt. But before using such cells for practical purposes they must be observed for a longer time till one is sure that their behaviour will not be altered by age.

These are the principal results gained during the last time in the Reichsanstalt on this matter. Some of them will be already known here, but I hope to have given new proof that the Clark cell is a very accurate standard for E.M.F. and a good measuring instrument for practical purposes.

AN ELECTRIC LOCOMOTIVE.

The accompanying illustration represents an electrical locomotive recently made by the General Electric Power and Traction Company, Limited, of 35, New Broad-street, E.C., at their Kentish Town Works, and is part of a large installation supplied to the Greenside Mining Company,



Cumberland. The locomotive is for mining work underground, the road on which it runs being in some places as narrow as 32in., the gauge of rails being 22in. It was found impossible in the small space available to place the motor across the frame with its shaft parallel to the axles, so it was arranged parallel to the rails. Three reductions of gearing are employed, one necessarily being through bevel gearing. The whole framework of the machine is hinged from the driving axle, which is made exceptionally strong for the purpose; the weight on the other wheels being taken through strong spiral springs on the top of gunmetal axle brasses.

The design of the "Immisch" motor, as shown, was chosen owing to the protection afforded to the field windings by this type of machine. The motor is series wound for a difference of potential of 200 volts, and develops 15 brake horse power, at 1,000 revolutions per minute. The length of the road is 1,200 yards, and the current is collected from two bare copper wires carried on insulators overhead. The E.M.F. is reduced from 500 volts to 200 volts by means of a motor transformer placed at one end of the line. The whole installation is rendered doubly interesting from the fact that a copious natural supply of water on the side of a hill is utilised as a prime source of power to drive a large Vortex turbine, the water being conveyed down the hill through 15in. pipes. A building has been erected on the hillside of this wild-looking country, in which the turbine drives an "Immisch" four-pole dynamo, which develops 100 e.h.p. at about 600 revolutions per minute. The dynamo is compound wound, with a working difference of potential of 600 volts, and supplies current also for motors driving pumping and winding plants, besides lighting the colliery both above and below ground.

THE DEVELOPMENT OF THE TELEPHONE.

The Duke of Marlborough writes to the *Times* as follows:

You have on several occasions done me the favour of inserting letters on the question of the development of the telephone in this country, and I venture to make one more appeal for space in your columns for a few further remarks on this subject.

There seems to be a misconception in certain quarters of the Press that the arrangements which have been come to between the two great telephone companies, as the result of their mutual agreement, are not likely to bear any immediate useful fruits in the public interest. It will not be long before this misconception is cleared up by the efforts which these companies are about to make to introduce, not only in the metropolis, but also in all the other large towns of England, a system of telephony more perfect even than any which exists in other European countries. The public have been led to suppose that the competition of these two companies among themselves might have produced this result in a more satisfactory manner since competition must have led to rate cutting between these two rivals in this industry. A little consideration of the matter would, however, show that, though a lower scale of

charge might have been produced by competition, the eventual cost to the public and also to the shareholders would have been considerably greater. I need not instance the disastrous effect of rate cutting and competition generally, as they must be very well known. We have some notorious instances of the waste of capital and the cost to shareholders of rate-cutting enterprises in the matter of American railways, and with regard to the telephone the consequences would have been even more disastrous. The establishment of two completely independent rival systems of telephony, say, in the metropolis, would mean that when the amalgamation eventually took place on the surrender of one of the rivals the victor would become possessed of a system which would be no earthly use to amalgamate electrically with the other. The whole system would thus be crystallised into a bad system of distribution which could not be altered, and the public would therefore be, electrically speaking, inefficiently served.

As to the cost to shareholders of a competition, that speaks for itself; and, as to subscribers, though they might appear to have the advantage of lower rates, they would have great inefficiency, and they would also be compelled to pay two telephone subscriptions instead of one and have two sets of instruments in their business premises or homes. All this will now be avoided by the working arrangement that has been come to between the two telephone companies. The area of England is so large that the demand for capital expenditure will be so great that the apportionment out of areas should present no insuperable difficulty to the respective companies. As to commercial arrangements there is no reason to see that these should present any insuperable obstacle to a harmonious scheme of development, considering the fact that both companies are in harmony with the General Post Office, and are willing and ready to assist in the development of the great trunk system and inter-trunk connection throughout the country which the Government is commencing. It is not at all improbable that the demand for the use of the telephone throughout this country will increase to an extent little anticipated, and that in the course of a very few years instead of 40,000 subscribers, as there are at present, the number will reach nearer 200,000, owing to the demand which will be created to speak over the Government trunk systems. We have as yet had no experience of the use of the telephone in England, but with the knowledge which is at present possessed by electricians in this country and abroad the two companies are now in a position, acting together on a settled plan, to establish systems of distribution on the twin-wire principle throughout the large towns of England, which will practically result in the establishment of a new industry. By the Act which was passed last session, the Government taking all the receipts on these trunk lines, the profits of distribution alone are left to the companies. The organisation, however, which it represents to carry out this work efficiently is enormous, and would require the creation of a new public department if the country were to ever undertake the working of the system itself.

As to the matter of rates this question produces some difficulty to determine at present, owing to the Government having established a system of telephone areas which will necessitate sound consideration on the part of the companies before establishing their new scale of charge. The first requirement to be met is undoubtedly efficiency. This applies not only to private service to subscribers' houses, but also with regard to the connections which are now to be made with the post offices throughout the country and the establishment of call offices, which should be located in every town in all convenient situations. In the matter of price it must be remembered that there will be great disadvantage in having the rate so low that the demand would become larger than it would be possible to meet conveniently from an electrical point of view. If every householder throughout the country possessed a telephone the amount of unnecessary talking which would take place is somewhat inconceivable, and in some ways it is better that the price should be one which should have some relation to the purposes of the user. For the general convenience of the public call offices should be largely multiplied, so that no one should be deprived from the use of the telephone from the charge being too high for a private instrument.

I observe in your to-day's issue the publication of the statistics of the telephone companies in the United States, from which it appears that the number of subscribers has grown between 1880 and 1890 from 48,414 to 227,357, and that the net earnings in the year 1890 from this industry represent 5,260,712dol. on a capital expenditure of 14,605,787dol. With regard to Sweden, which is probably the European country which has developed the telephone business more completely than any other, the system of Government trunks and local exchanges has arrived at a wonderful state of development. From what I have seen of the working of the telephone in that country the facility with which persons in one town converse with those in another is quite remarkable. The subscriber calls up the Stockholm exchange, say, and requests to have a conversation arranged with either Malmö or Gottenburg. The trunk operators communicate together by comparing the lists of persons who have appointments, and the operator at Stockholm telephones back to the subscriber the hour at which the conversation required has been negotiated. In the busy time of the day it may take some two or three hours before the conversation can take place, at other times half-an-hour is sufficient, and even less. It is easy, therefore, to see, when this system is properly applied in England by the action which will now be taken up by the General Post Office in laying inter-trunk wires all over the country and by the action of the telephone companies establishing an efficient distribution in all telephone areas, that the development which has taken place in America can be easily equalled by that which must come about in this country in a remarkably short time. England is an ideal country for the development of the telephone. It is inhabited by 36 millions of people, all living in a small area, and there is no town so distantly situated from another that they cannot be put into telephonic communication. The companies have thoroughly realised the situation both from the point of view of the public demand, and from the point of view of electrical knowledge, and it is certain that a new era is about to commence in this important industry which will largely change business relations throughout the country. To be able to hold a conversation of a thoroughly audible character between Glasgow and London may save several letters, telegrams, and also a railway journey. The price at which this boon has to be paid for is no measure of the value to the business man in time and labour. In large cities, such as London, the saving of time and expense in journeys in cabs, in making appointments for interviews, and the sending of letters is often enormous. All this development has been impossible up to now. The facilities which the telephone companies possessed were absolutely insufficient even to carry out a single-wire system in an efficient manner. The powers which the Post Office now possess will be conceded by the department to the telephone companies under certain conditions, and it is confidently believed that these powers will be sufficient to enable the companies to establish underground twin wire systems in all large towns. No doubt, if Parliament would have treated the telephone companies in the same liberal manner that the electric light companies have been treated, there would be less expense and less difficulty in laying the telephone distribution system. It is hoped, however, that these difficulties, which still exist, will be all successfully surmounted, and that before long London will have a telephone system laid underground capable of serving 50,000 subscribers in the metropolis alone; while the other large towns of England will be equally well engineered from the telephonic point of view.

As there seems to have been some misconception in the public mind as to the attitude which the companies have assumed towards one another and also as to the relation of the companies to the scheme which has been formed by the Post Office, I shall be very glad if, by the insertion of this letter, the public may see that the Act which was passed last session regarding the telephone industry and the action of the companies themselves is likely to bear immediate and important fruits.

Major-General Webber, R.E., has also written to the *Times* on the same subject, as follows:

Sir,—Ever since the prospectus of the New Telephone Company came out, on July 29 last, the public interested in the use and progress of telephony in this country have waited patiently for a statement such as the Duke of Marlborough has favoured us with in your issue of this date.

That some such statement was necessary was obvious as soon as it became apparent, by the constitution of the directorate of the Board of that company, that its control must necessarily fall into the hands of the representatives of the National Telephone Company, who occupy half the seats, and whose knowledge and experience of the subject must give their influence a preponderating weight in its deliberations.

May I ask the public, through you, to consider if the letter of the Duke of Marlborough has done anything to dispel the conviction, which has naturally arisen in their minds, that the recent developments can do anything else than perpetuate a great monopoly which the possession of patents in 1880 and their protection since that date created and maintained up till now, to the enormous retardation of the industry and with the result of a telephone service in this country second to none in inefficiency?

The Duke of Marlborough, in his able letters to you last year, was the vehement representative of the expression of the national discontent on the subject. His letter to you, Sir, of yesterday is not the only instance of how easily the assumption of "office" may completely justify what, when "out of office," appeared worthy of every kind of animadversion.

To a large extent his Grace's letter is a repetition of the well-known and oft-repeated advantages to the community of an efficient system of telephone exchange communication and its eminent adaptability to the commercial and domestic wants of this country.

He then proceeds to make wide promises as to the future performances of the "two great telephone companies."

As regards these promises, it may be observed that they are identical with those held out by the Bell and Edison, the United, and the National Telephone Companies in the early part of the last decade, except that to the "two great companies," now practically "one," is left the work of providing for "distributing" what the Government trunk lines will convey from centre to centre.

The Duke, in admitting to you that "we have as yet had no experience of the use of the telephone in England"—a postponement brought about by a monopoly—claims that this new monopoly, the character of which is undisguisable, will confer a great boon on the public, because he proposes to adopt certain electrical arrangements, the advantages of which were, however, nearly as well known to telephone engineers in 1880 as they are now.

Is it to be expected that, even while acting as the handmaid of the Postal Telegraph Department (itself a huge State monopoly), a private undertaking—or two undertakings, practically, under one direction—is likely to become suddenly the benefactor of its customers, as suggested by the Duke, or that there is any hope of its becoming "a system of telephony more perfect even than any which exists in other European countries"?

But in using all the well known arguments in favour of monopoly his Grace has "let the cat out of the bag," but with becoming reserve.

He deprecates all "competition" and "rivalry," as if we in this country of railway and other competition do not know its value when we have to be served well and cheaply. His words with reference to the past are worth quoting. "Though a lower scale of charge might have been produced by competition, the eventual cost to the public and also to the shareholders would have been considerably greater."

Because London has not had the wholesome advantage of this "would have been," it is that we have had (as the Duke states) "no experience of telephony," not only as regards efficiency, but as regards economy of rates.

It would take too much of your space to show how all these "would have beens" can be scattered to the four winds, but I will quote once more what I submit is a most "damning" admission in the letter: "In the matter of price it must be remembered that there will be great disadvantage in having the rates so low that the demand would become larger than it would be possible to meet conveniently from an electrical point of view."

Between the lines only the monopolist will fail to see that the demand for telephone facilities, which, but for monopoly, would long ago have reached vast proportions in this kingdom, is to be regulated, as heretofore, by the facilities which the companies choose to afford and by the charges they select to make.

In 1884, in a paper I read before the Society of Arts, I attempted to describe the vast development of the industry which its adoption into the daily life of the people ought to bring about; I showed how no electrical difficulties lay in the way of practically indefinite extension, how the then subscription of £20 per annum might be easily reduced to £8 for all ordinary demands, and how desirable it was that if any great advantage (the existence of which I deny) was to be obtained by the public from monopoly, it should be in the hands of the State, when the light of public opinion can, at any rate, be brought to bear on the conditions of efficiency and cost.

The spread of the industry I had in view did not exclude "the householder," as the Duke of Marlborough suggests, and did not relegate that individual to the use of a "call" office, nor confine it to a paltry 200,000 subscribers. Nothing since then has occurred to alter the conditions then propounded.

So long as the Duke bravely combated the existing state of things and realised that they were due to the absence of healthy competition, no one more cordially went with him than I did; but there is now no misconception in my mind that the fruits which the monopoly (perpetuated by him) must bear, in spite of the Act under which he attempts to shelter it, will fall far short of what the public has had a right to expect after patiently waiting for more than 12 years for an efficient and cheap telephonic service.

CORNWALL POLYTECHNIC EXHIBITION.

On Tuesday, August 23, the sixtieth annual exhibition of the Royal Cornwall Polytechnic Society, held in the Polytechnic Hall, Falmouth, was duly opened. In the absence of the president, Sir Joseph Pease, Bart., M.P., owing to domestic bereavement, the opening ceremony was performed by Colonel Tremayne. The same evening a highly interesting lecture, entitled "A General View of the Application of Electricity," was given in the large hall by Mr. R. N. Worth, F.G.S.

This year the exhibits seem to be exceptionally varied and highly interesting. All goods shown are divided into 12 sections, which includes mechanics, fine arts, photography, and natural history. This year a successful effort has been made to secure a representative display of electrical goods and appliances. Largely owing to the energy displayed by the secretary, Mr. Edward Kitto, the society may be congratulated on having been the means of bringing together a most comprehensive and complete collection of electrical goods.

Messrs. Veale and Co., electrical engineers, of St. Austell, are showing a number of appliances actuated by electricity. Among the other exhibits at this stand is an electrically driven pump, which is capable of raising 17 gallons of water per minute to a height of 60ft. The motor used is very small, and was specially constructed by Messrs. Veale for this purpose. To work the pump at full power it requires from six to eight amperes, at a pressure of 100 volts. Among other goods shown in action at this stand are electric blowers and fans, and electrically driven screw-cutting lathe, and electrically-heated flat and curling irons, kettles, and other similar domestic appliances similar to those shown by Messrs. Crompton and Co. at the late Crystal Palace Electrical Exhibition. Messrs. Veale, who we understand are Messrs. Crompton's agents for Cornwall, are showing samples of this firm's dynamos, arc lamps, and measuring instruments.

Messrs. Benham and Froud, of London, have a good display of their well known electric light fittings.

The General Electric Company, of London, are showing electrically heated irons and double surface heaters, electric fans, ventilators, motors, and a large assortment of electrical accessories.

The Lithanode and General Electric Company, of Millbank-street, London, S.W., have a good display of Lithanode batteries chiefly of the portable type. At this stand the Stella Lithanode miner's lamp is well represented; they also have a number of portable hand lamps for travelling and other purposes. A complete outfit, including battery, wires, switch, lamp and holder, etc., similar to those now being supplied to the London omnibuses, is being shown in action. In addition to the large Frankland Lithanode cells, as used for installation work, this company have on view brougham electric lamps, medical batteries, and small testing cells.

Mr. W. J. Corse, of Old Town-street, Plymouth, has a good selection of medical batteries, electric cigar lighters, distributing and switchboards, and other electrical apparatus of a similar nature, all of which we understand are his own manufactures.

Mr J Blight, jun, of Falmouth, is showing bells, burglar and fire alarms, telephones, and other electrical signalling apparatus. At this stand may be seen a somewhat novel development of the ordinary tread door alarm. This arrangement appears to be like a doormat, but underneath the carpet are placed a series of laths, somewhat after the fashion of a Venetian blind. Each alternate lath is supplied with fine flat spring contacts placed a distance of about six metres from each other. In each mat there are about 40 separate contacts, any of which may be caused to start an electric bell by simply pressing it. By this simple arrangement it is nearly impossible to enter or leave a room where it is placed without bringing into action the alarm-bell.

The mechanical exhibits are highly interesting. **Messrs. Crossley Bros.**, of Manchester, are showing one of their petroleum gas engines. This machine is used for working an air compressor for actuating rock borers and other similar pneumatic contrivances. The new engine is of the horizontal type, is stated to be 4 h.p. nominal and 10 h.p. indicated, and it only consumes three-quarters of a pint of paraffin oil per horse-power hour. If all that is said about this engine is reliable, there is a great future for it for electric lighting purposes.

Messrs. Weyman and Co., of Guildford, are showing the "Trusty" oil engine, which machine, it is stated, has been specially constructed to consume common oils and paraffins. The makers assert that oils of a specific gravity of 800 and upwards, and whose flash point ranges from 80deg. to 300deg. F., may be safely used with this machine.

Mr W. B. Rogers (Messrs. Crossley Bros.' representative) is daily showing in action a new pneumatic caulking tool of very ingenious construction. The new labour-saving machine, which we understand is now being adopted in most of the large shipbuilding yards in this country, is said to caulk the heaviest class of plates at the rate of 3ft. per minute.

Messrs. Stephens and Son, of Carn Brea, Cornwall, are exhibiting their well known "Climax" rock drills.

Messrs. Gates, of Queen Victoria-street, London, have working a small rock and ore crusher which is driven by a small electromotor.

The following awards have been made:

Silver Medals.

Messrs. Veale and Co., St. Austell.
The Lithanode and General Electric Company, London.
Messrs. Benham and Froud, London.

Bronze Medals.

General Electric Company, London.	R. B. Rogers, Falmouth.
W. H. Perrow, Truro.	W. M. Hodges, London.
	W. H. Corse, Plymouth.

Commended.

Messrs. McGeoch and Co., Glasgow.

COMPANIES' REPORTS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY.

Directors: Sir David L. Salomons, Bart., chairman; the Duke of Marlborough, the Earl of Suffolk and Berkshire, the Hon. Alan Charteris, Joseph Bevan Braithwaite, jun., Edward Lucas, Colonel B. H. Martindale, C.B., Frederick W. Reynolds.

Report of the Directors to be presented to the shareholders at the second annual general meeting of the Company to be held at Winchester House, Old Broad-street, E.C., on Thursday, September 1, 1892, at 2.30 p.m.

The Directors beg to submit their first annual report and statement of accounts for the period ended June 30, 1892. The Board has constantly pressed forward the necessary work, and the progress made is satisfactory. All the provisional orders and contracts are now in the possession of the Company, and the former have received the Royal assent. The Directors have secured on favourable terms the freehold of the Bankside central station, and have entered into an "agreement for a lease" of 90 years for the other central station at Wool Quay. Suitable buildings have been erected for all plant now running. Additional buildings for the machinery on order are in progress, the work for which is being carried on by night and day. Sites for several transformer stations have also been acquired, and the necessary work of construction and equipment is far advanced. Contracts for the full equipment of plant for the generating stations have been entered into under such conditions and specifications as will ensure all material and work being of the highest class and efficiency. There is already installed machinery of a capacity of 700 public arc lamps, and 23,000 8 c.p. glow lamps, including reserve. Additional machinery of a capacity of 56,000 8 c.p. glow lamps is being constructed, part of this is expected to be running by the end of October, and the remainder in the early part of 1893. The arrangements for duly executing this work within the limited time allowed by the contracts formed the subject of serious consideration by the Board. With the object of avoiding the inconvenience to the public inseparable from frequent opening of the same streets, it was decided to lay, at one operation, "ways" sufficient for immediate requirements, together with a number of spare tubes to meet all probable developments of the Company's business. By recent legislation, electrical supply companies are authorised, subject to certain consents, to lease for telephonic purposes any spare tubes they may have. One hundred and eighty-four arc street lamps were in use on June 30. The greater number of lamps contracted for will be in operation by about the middle of September. The final date for completion specified in the contracts is the 5th November, 1892. The demand continues to be exceedingly good. On June 30 signed applications had been received for 32,028 lamps, mostly from the limited area in which current was then available. Of this number 11,800 were connected up. The Directors have endeavoured to make their capital outlay earn revenue at the earliest possible moment, having regard to the proper execution of the work and the provision of adequate reserve power. The result is that a considerable income is already accruing. Public and private lamps installed at 30th June were estimated to be earning at the rate of £11,600 per annum, a figure which is daily increasing. From calculations based on the lamps already connected to the Company's mains, it appears that the consumption of current per lamp installed in City offices, shops, etc., will be much greater than was anticipated. There is every indication that the position of the Company is exceptionally favourable. **Messrs. W. H. Pannell and Co. retire, and, being eligible, offer themselves for re-election.**

Dr. CAPITAL ACCOUNT, JUNE 30, 1892.

	£	s.	d.
Share capital authorised:			
£400,000 in 40,000 ordinary shares of £10 each, and £400,000 in 40,000 preference shares of £10 each	800,000	0	0
Share capital issued:			
36,410 ordinary shares of £10 each	364,100	0	0
Less calls in arrear	1,514	0	0
	362,586	0	0
	£362,586	0	0

Note.—Under existing contracts relating to the equipment of the stations and other works there are further contingent liabilities, which become due only after delivery and final testing of the plant.

Cr.	£	s.	d.
Amount paid to the Pioneer Company under the agreement of 13th July, 1891, for works executed, and other matters	94,000	0	0

	£390,529	9	8

BUSINESS NOTES.

Western and Brazilian Telegraph Company. The receipts for the week ended August 19 were £2,603.

Agent Appointed.—Mr. Leoline A. Edwards, of 19, Laurence Pountney-lane, Cannon-street, E.C., has been appointed sole London agent for T. L. Hemming and Co., Limited, electrical engineers, of Birmingham.

Ludgate-hill.—The most recent addition to their orders for the electric light received by Messrs. Evans, Stewart, Palmer, and Co., is a large installation they have commenced at Nops's Electrotype Agency, 19, Ludgate-hill, E.C.

Electricity Supply Corporation, Limited. This Company has declared an interim dividend for the half-year ended June 30, 1892, at the rate of 5 per cent. per annum on the ordinary share capital of the Company, after payment of all interest on debentures.

City and South London Railway Company.—The receipts for the week ending August 21 were £724, against £728 for the same period of last year, or a decrease of £4. The total receipts for the half-year have been £6,148, against £5,680 for the corresponding period of 1891—an increase of £468.

Newcastle.—Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle-on-Tyne, are extremely busy in both their electrical and engineering departments. In the former department they have just secured the contract for the lighting of the Co-operative Wholesale Society's premises in Waterloo-street and Thornton-street, Newcastle-upon-Tyne. This installation is perhaps the largest driven by gas engines in the kingdom, the plant consisting of three 25 n.h.p. nominal gas engines to give 55 effective horse-power each, three "Tyne" compound-wound dynamos to run 600 16-c.p. lamps each, and about 800 16-c.p. lamps fixed throughout the premises. In addition to this the firm have the contract for lighting the Ashington Colliery throughout, and are also lighting Messrs. Chadwick Bros.' mill in Russia. They have more recently secured the contract for an electric pumping plant for the Newton Colliery Company; this plant is to be capable of delivering a maximum of about 200 gallons of water per minute. In the engineering department, they are extremely busy with their specialities in connection with auxiliary machines for warships. They have in the hand for the Admiralty six duplex pumps of the Worthington type, with cylinders 9 by 6 by 9; they have also in hand an order from the India Office for their Admiralty type of pump, and are building a considerable number of this type of pump also for various contractors doing Admiralty work. They are also busily engaged with electric fans, having recently received orders for a considerable number.

PROVISIONAL PATENTS, 1892.

AUGUST 15.

14674. **Improvements in electric telephonic transmitting apparatus.** Alexander Marr, 70, Market-street, Manchester.

14676. **Improvements in commutatorless direct current dynamo-electric machines.** Arthur Cuthbert, Rosebourne, Castle Hill, Maidenhead.

14709. **A method of making and using bionomic baths, to mechanico-chemically and hydro-electrically exalt the health of the people.** James Darsie Morrison, 8, Quality-court, Chancery-lane, London.

14719. **Improvements in and relating to electrical storage batteries.** Thomas Floyd, 11, Furnival-street, Holborn, London.

NOTES.

Taunton.—The extension of the underground mains has been commenced.

W. H. Preece.—Our contemporary, the *Machinery Market*, contains a portrait and biographical sketch of W. H. Preece, F.R.S.

Eastbourne.—In Eastbourne, in spite of the electric light, the gas company's business compels them to spend £10,000 for extensions.

Glasgow.—The æsthetic population of Glasgow are exercising their minds about the possible disfigurement of Kelvinside by a central station.

Electric Launch Company.—The Thames Electric Launch Company has been taken over by Mr. Andrew Pears. Mr. Sargeant remains manager.

Bradford.—Electrical communication is now used for fire alarm work. The necessary apparatus has been installed by Mr. O. Firth, electrical engineer, of Bradford.

Derby.—Tenders for electrical plant for Derby will be required soon. Messrs. Bramwell and Harris are the engineers, and tenders for the buildings are already invited.

Kingswood.—Complaints of the power of the incandescent lamps at Kingswood have elicited a reply from the company that they are intending to put in fresh lamps.

Budapest.—The Municipal Authorities of Pest have signed a contract with the local gas company for the general introduction of the electric light for the illumination of the public streets.

Taunton.—The crusade against the electric light is still continued, but it is clear from whence it arises. Mr. J. Standfast, writing to a local paper, says "the gas company having proved too strong for them."

Calcutta and Madras Telegraph.—The length of the new wire which the Telegraph Department is about to erect between Calcutta and Madras, through Manmad and Nagpore, is stated to be 19,000 miles.

Genoa.—We learn that a favourable report has been received by the Superior Court of Genoa from the State Railway Commission to grant the concession for an electric tramway on the Sprague system, to be opened by the 31st of December next.

Conservative Club.—The Conservative club in St. James's-street, which is being redecorated, is to be wired for some 400 electric lights, under the superintendence of Mr. A. A. C. Swinton as consulting engineer. Tenders for the work have already been obtained.

Brain's Conduit System.—On Tuesday last an experimental line on this system was inspected at the works of the Telegraph Manufacturing Company, at Helsby. Our description of this system must remain over for another issue, when we hope to illustrate its peculiarities.

Electrolysis.—According to the *Journal* of the Electrical Society, M. A. Chassy proposes to substitute the following for the law as enunciated by Faraday, Becquerel, and Wiedemann: "When any substance whatever is electrolysed there is always liberated an equivalent of hydrogen, or the corresponding quantity of the electro-positive radicle.

Railway Carriage Lighting.—The new Royal saloon carriage for use on the Belgian railway has been fitted by the State railway engineer very completely with electric light. Julien accumulators are used, giving light for 10 hours. The recharging is effected at either of the stations which have electric plant. This carriage is the first to be lighted electrically in Belgium.

Colon.—We understand that the lighting of the town of Colon (in Cuba) has been given to M. J. Vallice, of Matanzas. The installation will be on the three-wire system, the mains being of naked wire carried overhead. It will comprise 1,200 incandescent lamps of 16 c.p., and 20 arc lamps lighted by two Desrozier's machines, and is to be carried out next November.

Electric Bath.—A new idea is described as a bath of electric light, the head being placed in a chamber full of incandescent lamps. The effect is said to be salutary and pleasant. The men in a testing-room get plenty of this kind of bath. Still, a company might earn sixpences for electric baths as well as for letting in the public to see the machinery, which itself might more often be done.

Telford Medals.—The Council of the Institution of Civil Engineers have awarded a Telford medal and a Telford premium to Alexander Pelham Trotter, B.A., A.M.I.C.E., for his paper on "The Distribution and Measurement of Illumination"; a Telford premium to Charles Preller Shiebner, Ph.D., A.M.I.C.E., for his paper on "The Florence and Fiesole Electric Railway"; a Miller prize to Charles Henry Wordingham, A.K.C., Stud.I.C.E., for his paper on "Meters for Recording the Consumption of Electrical Energy."

Marseilles.—An electric tramway has recently been established at Marseilles to serve the outskirts of the town in the direction of the Aix route. The line commences at the Cannebiere, ascends the Rue d'Aix, which has a gradient of 6 to 7 per cent., and proceeds as far as Saint Louis. Here is situated the terminus of the *octroi* depôt, and various important refineries and blast furnaces. The total length of the tramway, which consists of a double line nearly the whole of the distance traversed, is three and three quarter miles.

Dundee.—The Finance Committee of the Dundee Gas Commissioners have fixed the price of the electric light which is being introduced into the city at 5d. per unit, being 1d. less than is authorised by the Electric Lighting Order, and 1d. less than the price charged at first elsewhere. It was stated that the Secretary for Scotland had approved of the proposed borrowing for electric lighting purposes, the sinking fund being fixed to extend over 60 years. It is expected the works will be completed and the light supplied by November.

Alternating Current Motor.—Mr. Shippey brought in for our inspection this week one of the new alternating current motors which he is putting on the market, under the name of the "Pioneer." It it a small and neat motor, with two-pole single magnet wound with one coil. The peculiarity is in the armature, which is double wound with heavy and thin wires. It has a commutator like an ordinary motor and is self-starting. The one we were shown was fitted to a ventilating fan, and the motor, which is about ½ h.p., should prove very useful for this purpose.

Communication with Lighthouses.—The Royal Commission appointed to enquire into the subject of electrical coast communication arrived at Plymouth in the "Enchantress" from the Scilly Isles, and, after taking the evidence of local witnesses, left for the Start, Portland, and Portsmouth. In their present course they have inspected most of the lighthouses and lightships between Liverpool and Plymouth, and along the east coast of Ireland. Next week they proceed to the Goodwins, and after visiting also the Thames group of lights, will voyage north to Edinburgh.

City Transformer Sub-Stations.—The Consistory Court of London was applied to on Monday to grant a

faculty to authorise the construction by the City of London Electric Lighting Company of a transforming chamber in the churchyard of St. Nicholas Cole Abbey. The Chancellor of London reserved judgment. A similar course was taken in the case of the application that was made for a faculty to authorise the construction of a transforming chamber in the churchyard of St. Benet Finck, Royal Exchange-avenue. It is expected, however, that no difficulty will be raised.

Derry.—On Tuesday night some thousands of the citizens of Derry assembled in the Diamond and adjoining thoroughfares to witness a trial of the electric light, for the purpose of street lighting, under the auspices of the Corporation. The trial was a great success, and there has rarely been a better and steadier display. Mr. Blake is the acting electrical engineer. It is well known that many places in Ireland are looking forward to having the electric light, and at the forthcoming meeting of municipal engineers to be held in Belfast no doubt opportunity will be taken to examine into the question.

Italian Government Decree.—A decree upon the distribution of electrical energy has just been issued by the Italian Minister of Posts and Telegraphs. All instructions upon the insulation of wires, transformers, fittings, and so on are set forth. No high tension wires are allowed overhead in towns. All continuous currents above 300 volts, and alternating currents above 150 volts, are considered "high tension!" The decree seems to be a kind of Italian Board of Trade act. We hope it will not tend to discourage the extension of electrical enterprise in Italy, where up to the present great progress has been made in the electrical industry.

A Timely Reminder.—Those in charge of the machinery at central stations should remember that it is friction and not work that wears out a machine. It is, therefore, the object of every good mechanic to lessen the friction of every bearing surface, either by strict attention to the character of the bearing surfaces themselves, or by the application of carefully selected lubricators. Lubricators are used freely, too freely sometimes, on almost all machinery, but it is not always that the operators understand the nature of the lubricant that they employ, and consequently it often happens that they make anything but a wise selection.

Trafalgar-square Theatre.—This new theatre, which has been leased by Mr. Levenston, was thrown open on Wednesday night to the inspection of a large number of invited guests. It is situated in St. Martin's-lane, and may be described as of medium size, approximately to the Prince of Wales's. Mr. Emden, from whose designs it has been built, has provided for some 1,200 spectators. In the matter of upholstery an innovation has been successfully attempted. The prevailing hue of the interior is amber, which has a beautifully soft and delicate effect. The theatre is lighted by electricity, and the drop curtain represents a view of the Thames Embankment.

Croydon.—The chairman of the Croydon Gas Company when questioned at the half yearly meeting on the prospects of competition by electricity, expressed the opinion that there were very few shareholders in gas companies who would venture to speculate in electric lighting shares in Croydon for a few years to come, at any rate. He ventured to think that so long as they could sell gas at 2s. 10d. a thousand, the use of the electric light would be very limited in Croydon. As soon as they felt they could do so with confidence, the directors would lower the price of gas still more, and be able to cope with electricity in Croydon even better than at present.

Reading.—The Reading Gas Company, confronted by the electric light, as promoted both by a company and the Corporation, has decided on a Fabian policy. "Your directors," said the half-yearly report, "have observed that a company called the 'Reading Electric Supply Company, Limited,' and the Corporation of Reading have each taken preliminary steps for obtaining power by means of a provisional order of the Board of Trade for the purpose of supplying electricity for both public and private lighting. When the plans of the above two bodies are more matured, your directors will be prepared to take such steps as they may deem necessary for protecting the interests of the shareholders of the company."

Mill Lighting in India.—The *Indian Engineer* states that Messrs. N. N. Wadia and Sons, engineers, have fitted up at the Sir Dinshaw Petit Mill, at Tardeo, an installation of electric light, and nearly completed the plant for the transmission of power by electric means. This innovation is also put up by the City of Bombay Mills, at Chinchpoogly. It is the intention of the agents of both mills to work from seven o'clock in the evening to three or four the next morning by a second relay of hands. The present spurt given to the twist market is due to a large demand from China, which has sprung up quite unexpectedly. Almost all the mills have sold their production in advance up to the end of the year, and it is probably to meet such extra demand that electric lights are to be fitted up in the mills to work them at night.

Rotherham. — A correspondent of the Rotherham paper strenuously objects to the extension of the gas works, as the nuisance from them is already almost unbearable. He wants to know why electricity cannot be introduced, not only for lighting, but to supply electricity to give motive power for many small manufactures, such as stocking weaving, printing, driving sewing and sausage machines, and many others. For lighting purposes in the day time, only half-price, or threepence per unit might be charged, as at St. Pancras. He adds: "If our Corporation do not introduce the electric light, it is almost certain that in a year or two some other company will obtain powers to do so." He wishes they would, for "the advantage to the public health over our present barbarous system of burning gas in confined rooms will be incalculable."

Boiler Economy.—As is well known amongst engineers, the boiler is the least satisfactory part of a steam plant. Engines and dynamos can be made to give a combined efficiency of 85 or more per cent. from ingoing steam to outgoing watts. The boiler is the point where the greatest loss of coal energy takes place (after the always present loss of heat in actual steam conversion, of course), and the attention of engineers has been directed to this question with a view of preventing some of these added losses. Amongst these attempts at progress we see some have been directed to the prevention of corrosion and incrustation by the direct means of enamelling the whole interior of the boiler. It is stated that firms in Glasgow have found this process extremely successful, and that further tests will be made and the results published.

Bath.—The first of the fortnightly reports from Mr Gatehouse to the Bath Surveying Committee, as to the electric light, was submitted at the last meeting. It stated that there were 84 lamps burning $7\frac{1}{2}$ hours a day. Eight had been out for periods varying from 20 minutes to three hours. Six of these were out on the same night, and the regulation and cleaning of the lamps had been badly done in each case. Other particulars as to pressure, current, average energy, resistance, etc., were given, and Mr. Sturges said it was not necessary to report this. It would not be understood. The Chairman: Hebrew! Mr Ricketts

thought the inspector should give all the information. Mr. Morris also thought the entries should be retained, but it was of no great service to read them. The committee took this view of the subject. The report was passed.

Water Power and Electricity.—Arrangements have just been completed for lighting Overtown, the baronial residence of Mr. J. Campbell White, amidst the hills overlooking the Clyde, by electricity generated by the water power which is so abundant in this part. The installation, according to the technical description in *Engineering*, is for 300 lights of 16 c.p. It is computed that the system, as compared with the gas, which it supersedes, will in three or four years have paid for itself. The waters from the neighbouring hills are gathered into a reservoir of 700,000 gallons capacity, and into it there is said to be a continuous supply. From this point a 12in. cast-iron pipe is laid a distance of 640 yards to a turbine and dynamo house at the foot of a glen, the fall being 170ft. There are two turbines, each driving a separate dynamo, so that the plant is in duplicate, and thus there is little likelihood of the current falling at any time.

Ship Lighting.—A new steamboat, the "Grange," built by Messrs. Wigham, Richardson, and Co., of Newcastle-on-Tyne, for the Carron Company's service between London and Grangemouth, in the Edinburgh and Glasgow trade, made her official voyage on Tuesday from Tilbury out to sea and back to the company's wharf near the Tower. The party on board included Mr. McLaren, director, acting for Sir John Brodie, chairman of the company; Sir E. J. Reed, M.P.; Mr. Tweedy, representing the constructors of the ship; Mr. Cowan, Mr. Jardine, Mr. Robertson, a number of guests, several of the older officers of the company, acting in other days, and Captain Francis Carne, one of the new school at the head of passenger steamers. The vessel is splendidly engined, is furnished throughout in modern style, and electrically lighted. The "Grange" is 280ft. in length, 36ft. breadth, 17ft. depth, of 1,517 gross tonnage, and of 4,000 h.p.

Great Northern and City Railway.—On June 28th last the Royal Assent was given to a Bill for the construction of a new underground electric railway between Moorgate-street and Finsbury Park. The necessary preliminary details have now been worked out by the engineers, Sir Douglas Fox, Mr. Francis Fox, and Mr. J. H. Greathead, and the construction of the line will very shortly be commenced. A land valuation has been made by Messrs. Vigers and Co., and they estimate the cost at some £400,000. The whole cost of construction will exceed £1,200,000; this sum, however, includes everything with the exception of plant. The first directors of the company, which is to be called the Great Northern and City Railway, will be Lords Camoys and Lauderdale, Messrs. Roger Richards, Daniel Bayley, and John Hamlyn Boner, and the required and authorised capital is £1,500,000. The terminus will be at Moorgate-street, and stations will be built at Essex-road, Drayton-park, and the rail junction with the Great Northern Railway at Finsbury Park.

Dublin.—The correspondent of an Irish newspaper says, with reference to the Dublin lighting: so far the electric light in Dublin is a decided success. Every person you meet is for it. All the leading streets are lit with it. During the week thousands of people admired it, especially in O'Connell-street, where the lamps are placed at each side of the street, and so brilliant is the light that you could pick up a pin off the flags on either side. The gas-lights are still there, but they look only as yellow specks beneath the great white electric lamps, which are on metal posts not quarter as high as the wooden poles which support the electric lights in your city. It is now introduced into several hotels, and other places of public resort in Dublin. The corporation intend to light not only the large streets with this light, which is their own, but every one of the small streets as well with smaller lamps. It is said that the shopkeepers and merchants will also take it in as soon as the corporation are prepared to give it to them—so that in course of time it is believed it will prove a large source of revenue to the municipal body.

Electric Launches.—The following details are given of an electric launch known as the "Electra," built by the Electric Launch and Navigation Company of New York, for passenger service on the enclosed waters of the World's Columbian Exposition. She was built at Bay Bridge, and is 34ft. long over all, with a load water-line of 31ft. 6in., beam 6ft., and draught 26in. The storage batteries of the "Electra" are arranged along the hull the whole length of the craft, with seats on the top of them. The batteries are connected in parallel, but can, by means of a switch, be connected in series, and will, when so connected, give a maximum speed of 12 miles an hour; the normal speed, however, is 7 miles per hour, the company stating that they have found that the mileage by a single charge varies inversely as the square of the speed. The motor of the "Electra" is 4 h.p., but is capable of developing 12 h.p. Its normal speed is 600 revolutions, and its armature is coupled direct to the propeller shaft, which is constructed of Tobin bronze. The boat is fitted with electric lights and various electrical attachments, including a signalling trumpet.

Electric Lighting Plants.—A very neat guide to private house lighting has been issued by Messrs. Drake and Gorham, who have an acknowledged position in this class of work. Their book "Electric Lighting Plant and Accessories" contains some neat sketches of a small steam plant suitable for private house lighting. A semi-portable engine is shown driving a dynamo by belting in a neatly arranged engine-room, with tiled floor and electrically lighted, of course, with regulating switch at one end. Alongside, but partitioned off, is the coal bunker and an accumulator room, making a compact installation. A plan of this engine-house is also shown, so that a householder sees exactly what he is going to get. Another view shows a gas or petroleum engine plant in the same way. The pamphlet contains full particulars of wires, fittings, switches, and so forth required, and a number of well-cut blocks show the different switches and switchboards that can be used. There are prices of all these things, as well as instruments, and sample estimates for 50 and 100 light plants make a complete store of information for intending purchasers of installations.

Peckforton Castle.—An important electric light installation is being carried out at Peckforton Castle, Cheshire, the seat of Lord Tollemache, by Messrs. Barclay and Son, electrical engineers, of Regent-street, under the superintendence of their engineer, Mr. Ardebut. An engine-house has been built near the entrance to the grounds, which contains a 40 h.p. Robey engine, of the locomotive type, which serves the double purpose of working a sawmill and the dynamo. The latter is one of the new type of dynamos on the Scott-Sisling patent. It charges 56 E.P.S. accumulators. The whole arrangement is on the same plan as the "model country house installation" exhibited by the firm at the Crystal Palace, for which they obtained a silver medal. From the engine-house a cable, 900 yards in length, conveys the current to the castle. The wiring is being carried out on the concentric system, which requires no casing, takes up a very small

space, is very neat in appearance, and somewhat cheaper than the usual method. We fancy it is the first instance of a large private installation of this kind which has been fitted throughout on the concentric system.

Bradford.—The Gas and Electricity Supply Committee of the Bradford Corporation are making arrangements for the extension of the electricity works. The enlargement consists principally of the erection of two sheds on ground already enclosed, and of the laying down of a steel Lancashire boiler. These arrangements are being made in view of the increase in consumption that naturally takes place on the approach of winter. Last winter there were only three boilers at work, and the resources of the department were severely taxed. About midsummer a fourth boiler was laid down, but it was felt that a fifth was needed before the works could be fairly said to be ready for an emergency. How long this particular addition can be considered as spare plant it is hard to foretell. The demand for electric light is steadily growing, and very shortly the department will have to supply 700 lights for the Victoria Hotel, which is now been renovated. About 17 miles length of cable has now been laid down in the Bradford streets. This, however, only represents an actual distance covered of about four miles, though the busiest part of Bradford is now well supplied.

Maidstone.—At the last meeting of the Maidstone Local Board of Health, the following report was presented on the lighting question: "Your committee have had under consideration the question of preparing estimates and a scheme for the electric lighting of the borough, and the engagement of an efficient electrical engineer for that purpose. Two engineers have attended before and been interviewed at length by your committee. Your committee now recommend that Mr. W. C. Hawtayne be engaged by your authority to prepare the necessary plans, estimates, and specifications, and carry out the entire scheme. That Mr. Hawtayne be required to reside in Maidstone during his engagement. That he be permanently engaged to manage and start the lighting, and be required to act as residential engineer in charge of the works for a period of at least 12 months after completion. That during his engagement Mr. Hawtayne be paid a salary of £300 per annum." The adoption of the report was proposed by Mr. Barker and seconded by Mr. Cox, but in the course of the discussion which followed, the majority of the members were of opinion that the matter should be more fully discussed. A special meeting of the whole Board has been called.

Charging Accumulators by Alternate Currents. We mentioned some few weeks ago the news which until then had been unknown to English engineers, that the method had been found for charging secondary batteries by alternating currents. This statement was received with a good deal of incredulity, as was only natural, and yet at the same time so much has been done with alternating currents that the feeling was present, why not this any less than the other discoveries? We have recently had this news confirmed by one of our correspondents from Paris, who is in close communication with MM. Hutin and Leblanc, who are the experimenters in question, and we are assured that the method is certainly a practical success, at any rate on the scale on which it has been adopted in their works. The rectification of the current is carried out by special apparatus of the nature of condensers, which we hope to be able to publish before very long. It is too early, of course, to be led to believe that new central stations will be operated on this principle for some time, but if the practical difficulties are overcome, there is every reason to suppose that this method of storing the energy of the alternating current will prove as useful to engineers as the storage of the direct current.

Waterford.—On Thursday last week a special meeting of the Waterford Town Council, convened by the Mayor on the requisition of some members, was held to re-consider the question of the public lighting of the city; to rescind the resolution passed on the 11th inst. accepting the gas company's tender; to rescind a previous resolution deciding to light the city by oil; to accept the offer of the electric light company to light the city for six months; and to take competent advice on electric lighting generally. The Mayor presided. Alderman Toole proposed the resolution, and went into figures to prove that electric light was cheaper than gas. The Corporation of Dublin had a splendid installation for £20,000. Mr. Smith interrupted here, and said the estimate for the lighting of Dublin by electricity was £38,000. Alderman Toole stuck to his assertion that only £20,000 was expended in establishing the installation in Dublin. He mentioned that by sticking to their agreement with the gas company the Corporation would be sacrificing their provisional order, which cost them £500. Were they, in face of all he had pointed out—in face of the progressive tendency of the age—going back to the same condition of things that existed in the city 40 years ago? Alderman Redmond seconded the motion. The meeting was interrupted with many personalities, and the motion was defeated by 19 votes to seven.

An Electro-Photographic Thief Detector.—For some time past Mr. Triquet, a cigar merchant, of Toledo, Ohio, has missed cigars from the showcase in his office, and although the premises were watched by detectives for several days nothing unusual was observed. As a last resort he applied to an inventor of a flash light photographic apparatus worked by electricity. The apparatus was placed in the office and left to itself. A few days later it was found to contain a flash photograph showing two boys opening the glass case. The picture led to their apprehension by the police and subsequent committal to prison. The apparatus consists of a camera placed in a box which is closed by a shutter operated by a spring and escapement released by an electromagnet. The necessary flash light is got by means of a match, which presses against a rough disc. An electromagnet on the top of the camera box when excited by a current releases a detent, and allows the rough disc to strike a light with the match and ignite the flashing powder. All this occurs in a fraction of a second, and the shutter closes on the camera, retaining the photograph. The current is supplied by a battery, and is started in the circuit by an arrangement of contacts which are unconsciously closed by the thief. Thus the boys in opening the glass case unawares completed the electric circuit, which immediately exposed the camera, and kindled the flash light, much to their amazement. The apparatus is illustrated in the *Scientific American* for August 13, where a reproduction of the two startled boys is also given.

Cholera.—The world has been startled during the last week by the daily reports upon the outbreak and spread on the Continent, and a good many persons have had their holidays spoilt—not to speak of the horrors of plague and death in the affected parts. After Russia, Hamburg commenced the round, Bremen and Rotterdam have been seized, and Havre suffers a daily death-roll. We are tempted to ask whether electricity has no part to play in the fight with the deadly plague. It is possible to conceive it has. In Havre, for instance, the sewage is poured into the harbour and the surroundings are vitiated month after month, till the tropical warmth of the autumn germinates the seeds of disease. Means should be taken to neutralise this plague bed in the towns. We happen to know that

the authorities in Havre have already considered the application of electrical purification of their sewage. Plans were drawn out and the contract almost arranged with an influential English firm for a practical working of this method of disinfecting. Unfortunately, political elections intervened, and the scheme fell through. Possibly the execution of the project might have prevented the scores of deaths at this town. It may be worth while to press this aspect of the case forward, for every means possible should be carried out to prevent the outbreak of plagues, and cleanliness of water and air are the greatest factors in this connection. Fresh living air itself is a great aid in overcoming disease, and our use of high-tension electricity in purifying the air of fever wards is not yet sufficiently tested and adopted, and the usefulness of electrical action in stopping the spread of germ generation has been long acknowledged in the science of fermentation. If electricity could only come to the aid of medical science in these matters, electrical engineering would have done a great work in the sanitation of the world.

Fleet Street by Electric Light.—On Monday night Fleet-street was illuminated for the first time by the electric light. The scene gave many causes for reflection, and the lighting was regarded as a brilliant success. Light indeed are now the labours of those who are busiest from dusk to dawn in purveying the world's news. The scene of Doctor Johnson's lucubrations by midnight oil is now rendered vividly lustrous by the aid of modern science, of which the worthy doctor knew nothing, and it would be not less interesting for him to learn—if he could be interested in such matters now—that the scene of his labours was enlightened under the superintendence of one of his ancient enemies, a Scotchman, for the manager of the City lighting, as most of our readers know, came from the land o' cakes. Goldsmith, too, might have given us his opinion on the influence of advancing science on the decay of man; and Lamb—the genial Lamb—he who said he could weep with joy to see the fulness of life in Fleet-street—would have additional reasons for wandering at night, when the street is still crowded though other streets are forsaken, in the ghostly radiance of the electric light. Truly, if any place should be illuminated with the latest and best light, it is here. The most crowded piece of ground, probably, in all the earth, and crowded, too, with men of quick intelligence, leaders of thought in literature and politics, Fleet-street is gradually emerging from the squalor in which too many of the renowned London streets still exist. Noble buildings are rising, the air is clearer and purer, the streets are cleaner by far than in the olden time; and if only electricity can come to show up the dark and dirty courts, and can eventually feed our fires and rescue us from the fog fiend, we shall find Fleet-street one of the handsomest, as it certainly is now one of the most interesting, streets in London.

Electrical Engineering in Japan.—A large and important Government engineering enterprise was recently completed in Japan. Lake Biwa, having an area of 500 square miles, is situated about seven miles from the city of Tokio, and at an elevation of about 140ft. A navigable canal has been cut from this lake to Tokio, involving two miles of tunnelling and an aqueduct of considerable length. At the eastern extremity of the city, to which point the canal has been brought, there is a sharp decline of 118ft., from the base of which the canal is continued to the sea. This difference of level is overcome by inclined plane ways, 2,100ft. in length, on which boats are raised or lowered from one canal to the other. These ways are worked by electric power furnished from a Pelton waterwheel connected with a Sprague motor. The waterfall affords also a very valuable water power, a part of which has already been utilised for various mechanical purposes by means of electric transmission. The power station is established at the foot of the incline, and consists of three 8ft. and two 6ft. Pelton wheels, giving a total of about 600 h.p., supplied with water from the high-level canal by three lines of 36in. pipe, 1,300ft. in length, delivering water to the wheels under a head of about 100ft. These wheels are at present supplying power for three Edison dynamos of 80 kilowatts each, the current from which is distributed about the city within a radius of two miles, running rice-mills, spinning-mills, a watch factory, and various other machinery. One Thomson-Houston alternating-current dynamo of 2,000 volts supplies the city with 1,300 incandescent lights, as well as many arc lights. The above works, involving an expenditure of about £250,000, were planned by and executed under the direct supervision of Mr. S. Tanabe, an eminent Japanese engineer. They are said to be entirely successful, both from a scientific and commercial standpoint, and evidently will be the forerunners of many additional power transmission plants in Japan.

Incandescent Lamps and Current.—It was long thought, says *L'Industrie Electrique*, that incandescent lamps taking few watts were economical, but some experiments of MM. Siemens and Halske seem to point to the contrary. They may be economical for the moment, but after, no. The experiments were with lamps to take normally 1·5, 2, and 2·5 watts per normal candle. The actual watts per candle were determined after a given number of hours of burning, with results given in the following table:

Duration of lighting in hours.	Lamps taking normally 1·5 watts per candle.	2 watts per candle.	2·5 watts per candle.
0	1·52	2·01	2·51
5	1·91	2·03	—
10	2·43	2·21	2·52
15	2·81	2·38	—
20	3·19	2·48	2·52
25	3·40	2·57	—
30	3·77	2·71	2·52
35	4·07	2·91	—
40	4·15	2·98	2·55
45	4·25	3·03	—
50	4·45	3·06	2·69
55	4·46	3·25	—
60	—	3·46	2·71
65	—	3·51	—
70	—	3·63	2·79
75	—	3·67	—
80	—	3·83	2·89
85	—	3·93	—
90	—	3·99	3·01
100	—	—	3·09
110	—	—	3·22
120	—	—	3·26
130	—	—	3·30
140	—	—	3·53
150	—	—	3·58

The result will perhaps be better seen from the following:

	Type of lamps in watts per candle. 1·5	2	2·5
Length of test in hours	55	90	150
Initial luminosity	16	16	16
Final luminosity	4·5	7	10
Initial watts per candle	1·5	2	2·5
Final watts per candle	4·46	3·99	3·58

Showing that the lamps initially requiring final watts soon deteriorate and consume more, while those starting with the higher consumption continue to consume more constantly. MM. Siemens and Halske advise the use of lamps requiring from 3 to 3·5 watts per candle, never using those below three watts.

DUBLIN CENTRAL STATION.

DESCRIPTION OF THE MACHINERY.

The central electric lighting station which has just been erected for the Dublin Corporation is centrally situated in Fleet-street, at the rear of the old Parliament Houses. It comprises (1) engine house, (2) boiler house, and (3) offices and test and switch rooms.

Engine-house.

This is what may well be termed the most imposing part of the station. Here are erected the three sets of the two kinds of plant—viz.: The Lowrie-Hall high-tension alternating current system for supplying current to consumers' houses, and a continuous current Brush system for lighting the streets by means of arc lamps. For the private lighting there are three pairs of compound horizontal non condensing engines of 280 h.p. each, working at a pressure of 140lb. per square inch on the valve boxes and running at a speed of 85 revolutions per minute. High and low pressure cylinders are fitted to each engine, the admission and exhaust of the steam being regulated by the well known patent Corliss valve system. The fly wheels, weighing nearly 10 tons each, are 14ft. in diameter, and are grooved for 12 cotton ropes running direct to the dynamos. The engines are of Irish make, being specially built by Messrs. Coates and Co., of Belfast. There are two main ranges of steam pipes and one range of exhaust piping, the latter running from the low-pressure cylinders of the engines to the feed-water heaters, which are erected at one end of the boiler-house. The engine foundations are built of concrete and granite block from the depth of 16ft., where the solid rock was reached.

The Dynamos.

Coupled direct by 12 1¼in. cotton ropes to the engines are the patent Lowrie Parker alternating current dynamos, each giving an output of 75 amperes at 2,000 volts; or, in other words, each machine is capable of supplying current to 5,600 lamps of 8 c.p., or feeding on to a circuit wired for about 10,000 lamps. They are magnificent specimens of dynamo machinery construction. Their speed is 350 revolutions per minute. The mean speed at which the armature conductor is passed by the field magnets is about 6,000ft. per minute, and the number of alternations 10,000 or 5,000 complete phases per minute. The E.M.F. is 2,000 volts. All three machines are identical. The armature is stationary, with iron core of large section composed of the very best charcoal iron sheets, arranged longitudinally and in the same plane with the magnetic fields, clamped to the frame of the machine and thoroughly insulated.

An important feature of this dynamo is that the armature conductor coils are formed of narrow copper tape, each wound in a plane upon a piece of insulating material of the same thickness as the width of the tape, and rounded at the ends. The coils are thus of a flat link shape, the edges of the tape windings being exposed upon the flat surfaces of the coils, and therefore well able to resist deflection. These coils are placed close together upon the cylindrical inner surface of the armature ring, so that the axis of each coil is radial to the ring, and are secured to the same by strips of wood, screwed to the cheeks, and extended over the ends of coils, outside the line of travel of the magnets. By this mode of construction the whole of the conductor (except a small portion at the ends of the coils with the line of the field and therefore useless for inductive purposes) is placed in a strong and uniform field of force; each turn of the conductor is under exactly the same inductive influence, and at the same distance from the moving poles, and consequently in the best position for efficiency. Another great advantage is that no special means are required to keep the conductors from sagging, or lifting from their normal position; and, as no wiring or other like means are used for the purpose named, the clearance space between the revolving magnets and the standing conductors is reduced to a minimum. Furthermore, as the armature coils are simply secured to the face of the armature, they are easily removed or replaced as required, and this remark applies likewise to the magnet windings. The armature ring is parted upon the horizontal line, so that the upper half is removable for inspection or repairs. The moving part of the machine consists of a solid soft wrought-iron ring, with polepieces securely attached thereto, and is arranged so that the centrifugal force of the whole of the moving parts is taken by the ring. The base plate is of strong box pattern, and strongly ribbed and under flanged where it bears on the slide rails. The frame for supporting the laminated iron armature core is cast separate and bolted to planed facings. The plummer blocks for the bearings are also cast separate from the base plate, and secured thereto by bolts and lugs, and wrought iron wedge keys.

The bearings are two in number, 20in long. They are in halves, jointed on the horizontal centre and fitted with loose brasses, top and bottom. The brasses are of hard phosphor bronze. The bottom brass is so arranged that it can be removed without lifting the shaft, and yet well secured sideways; each bearing is fitted with two combined syphon and sight-feed lubricators. Each end of the bearing is provided with oil catchers, consisting of a chamber all round the shaft, by which the oil passing from the bearings is caught when thrown from the oil throwers provided on the shaft and conducted by a passage formed in the plummer block under the brass to a waste oil tank or receiver formed in the plummer block or the base plate. The shaft is of best mild steel, 6in. in diameter, the side thrust being taken by collars, forged solid on the shaft at each side of one bearing only; double grooves are cut for throwing the oil into the collectors at each end of the main bearings. Mounted on this shaft is a hub of cast iron, attached to the ring, on which the magnets are mounted in such a manner as to prevent any magnetic short-circuiting. The rings on the shaft for collecting the exciting current are insulated from the shaft and from each other by ebonite washers. The brushes and holders are supported from the base plate, and do not interfere with the bearings or plummer block; each ring is provided with two sets of brushes, each set being ample for collecting the maximum current; contact is kept by adjustable springs, and each brush is separately provided with a safe and easy means of lifting and keeping it away from the ring while the dynamo is in motion. Fixed to the dynamo is a pulley of suitable diameter for driving the exciter, turned with grooves for four ⅞in ropes.

The exciter is a series-wound machine, with drum armature, speed 800 revolutions per minute. The commutator is of ample size and entirely free from sparking, and provided with two sets of brushes and holders, each set of brushes being ample for collecting the maximum current, contact being kept by adjustable springs, and each brush is separately provided with a safe and easy means, when necessary, of lifting and keeping it away from the commutator while the machine is in motion. The lubricating and oil catching arrangements are similar to those of the alternating dynamo. Efficient means for tightening and driving the ropes are provided, consisting of two cast iron rails of heavy section, fitted at one end of each with forcing screws, provided with holding down bolts for the dynamo, the nuts of which are of rectangular form and sliding in grooves formed in the rails. The bolts being applied from above are removable without lifting the dynamo. The two rails are securely tied together with cast-iron distance pieces. Similar arrangements are supplied for the exciter.

The approximate weight of dynamo, rails, and exciter is 12 tons. The foundations of the dynamos below ground are all built of concrete from the depth of 15ft. 6in.

At the opposite end of the room are situated the three sets of arc lighting plant, comprising three vertical compound engines and three continuous-current Brush dynamos. The engines are 60 h.p., and run at a speed of 220 revolutions per minute. There are high and low pressure cylinders, the low-pressure being fitted with automatic relief valves. The flywheels are 8ft. in diameter, and grooved for eight cotton ropes, thus coupling the engines direct with the dynamos. These are of the Brush make, giving an output of 10 amperes at 3,000 volts. The speed of the dynamos is 800 revolutions per minute, and each machine is fitted on sliding rails for tightening the ropes. The armatures are of laminated iron, wound with coils in 12 recesses, the opposite coils being connected in series,

the free ends being brought out through the shaft, which is hollow, to the plates of the commutator.

A large travelling crane capable of lifting 10 tons is erected in the engine-room, and is used for moving and erecting the heavy portions of the machinery.

Boiler-house.

The steam-generating plant is comprised of four of the Babcock and Wilcox type of water-tube boilers, each capable of evaporating 8,500lb. of water per hour at a pressure of 150lb. per square inch. The total heating-surface in each boiler is 51 square feet. They are set in two batteries of two boilers each, each battery being provided with a steam receiver having outlets for the connections to the main ranges of steam pipes. Each boiler is composed of 14 sections or slabs, each section being composed of eight best lap-welded wrought-iron tubes 4in. in diameter and 18ft. long, connected at the ends with continuous staggered headers or "up takes" and "down takes," the tubes being fastened therein by being expanded into tapered holes. The several sections are connected at

Fig. 1.—Dublin Central Station, Fleet-street.

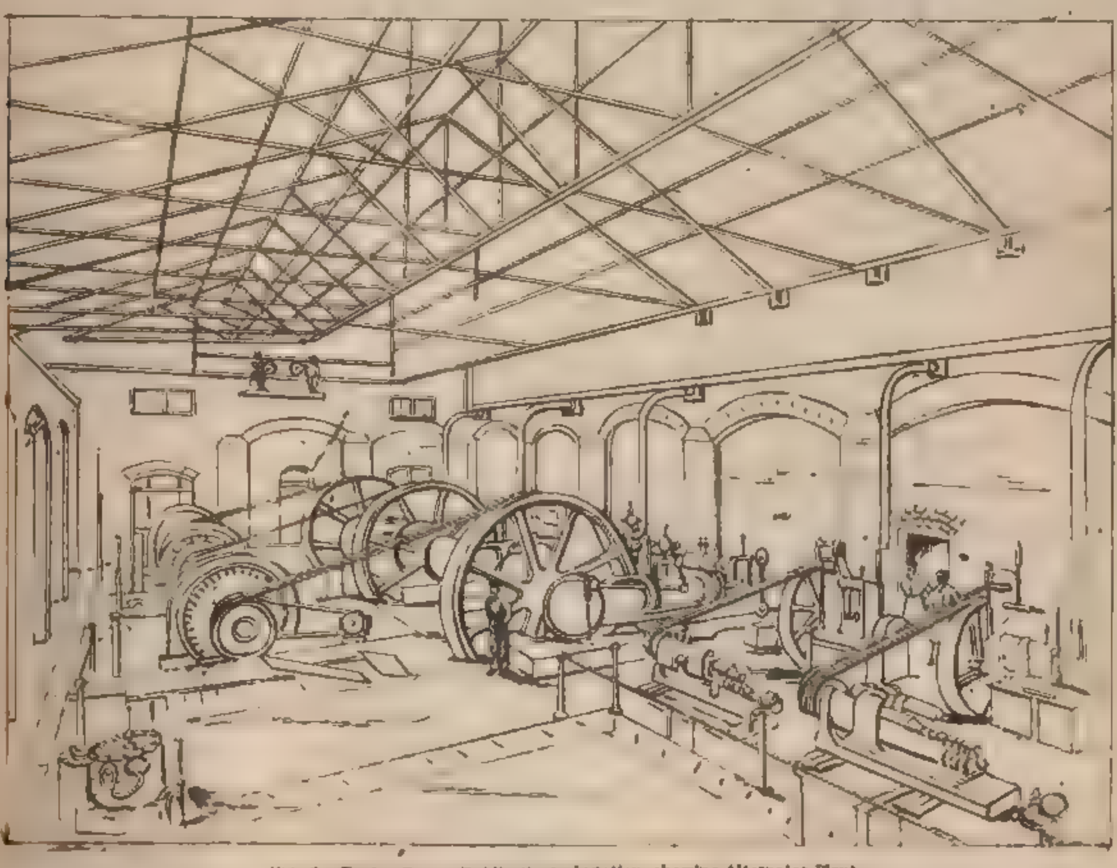

Fig. 2.—Engine Room, Dublin Central Station, showing Alternator Plant.

each end to two steam and water drums, and at one end with a mud drum, by means of lap-welded wrought-iron tubes 4in. in diameter and of suitable length, expanded into cored holes. The steam and water drums are 36in. in

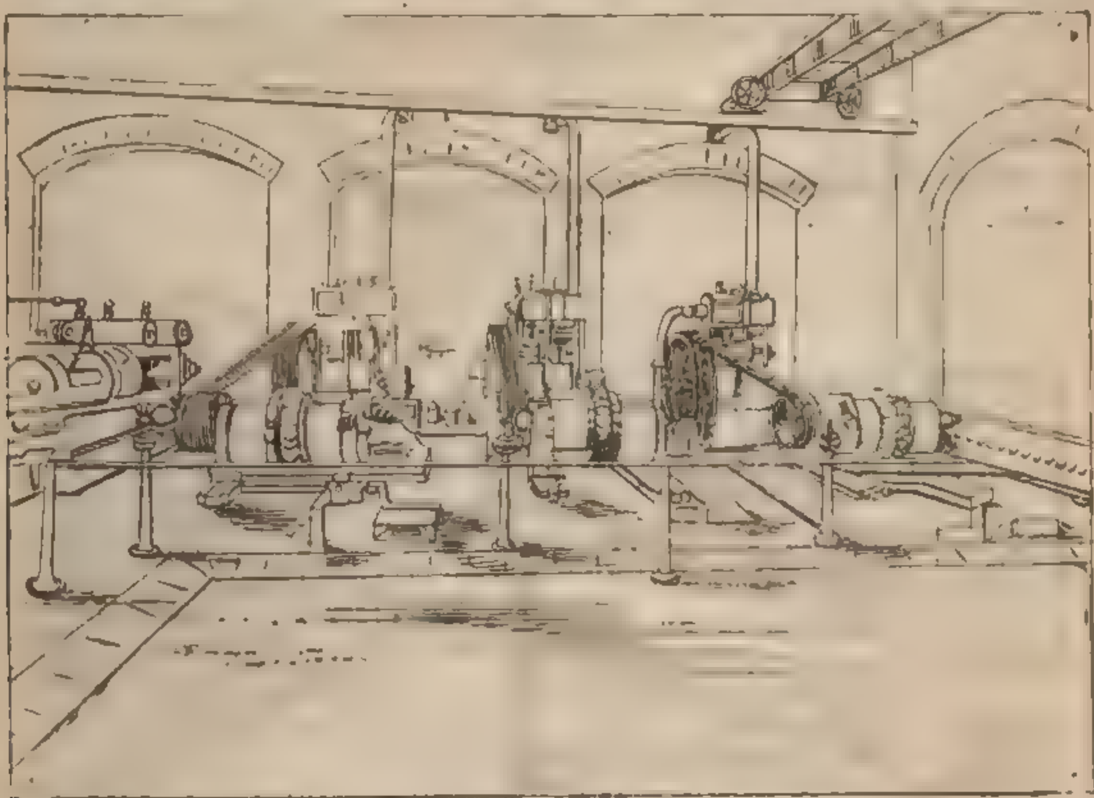

FIG. 3.—Engine Room, Dublin Central Station, showing Arc Plant.

diameter and 23ft 7in. long made of steel ⅜in. thick, and have longitudinal seams double rivetted and provided with a manhole at one end, and two nozzles, one for safety valve and one for taking off steam, 5in. diameter with 11in.

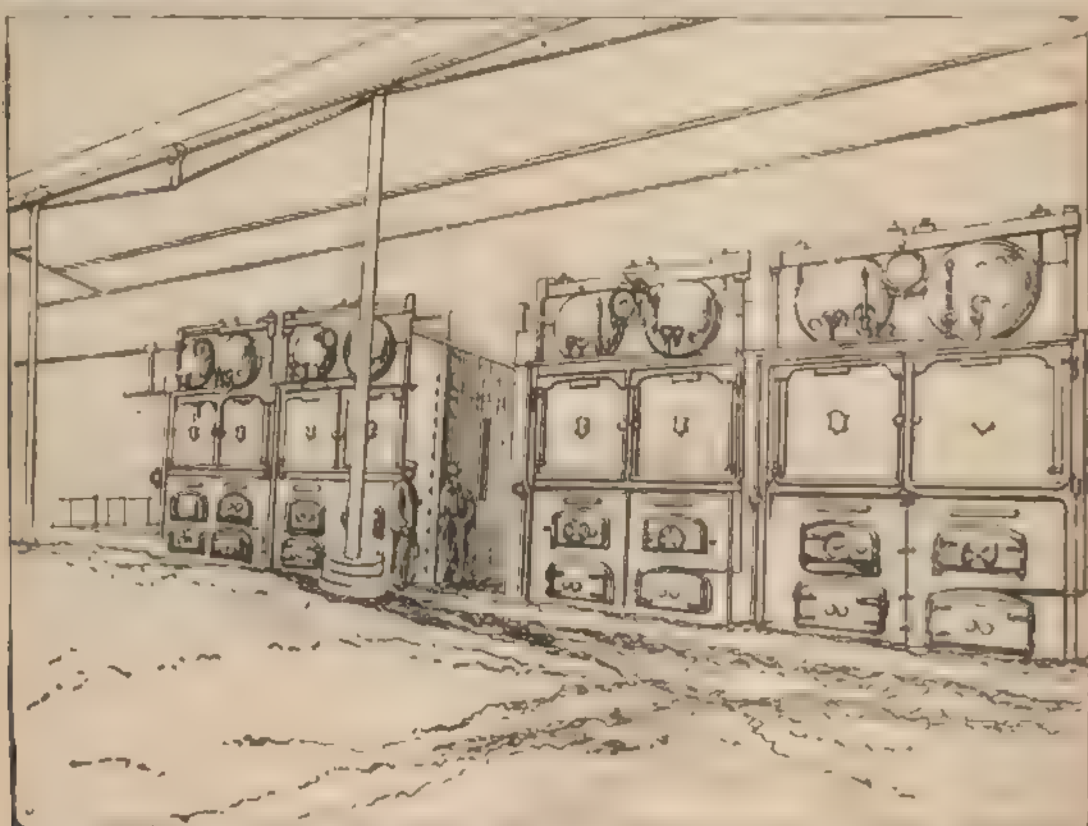

FIG. 4.—Boilers, Dublin Central Station.

flange, faced and drilled. Each boiler is fitted with two safety valves of 5in. diameter, set to blow at 155lb., and there is a steam pressure gauge in front which indicates the amount of pressure of the steam in the boiler.

In close proximity to the boilers are erected three Worthington steam pumps, each capable of supplying water to two of these boilers when fully loaded. There is also all the requisite wrought-iron piping for the connection between the pumps, boilers, and water-tanks, the latter being erected in front of the boilers over the coal bunkers. Close to the large chimney shaft are the three-feed water heaters, each heating a sufficient quantity of water to feed two of the boilers. They are connected with the main exhaust steam pipe, and are fitted with by-passes and a complete arrangement of stop valves to enable the exhaust steam from the engine to be sent through any of the feed water heaters or

past them. The exhaust pipes are carried from the heaters up the chimney to within a few feet of the top.

OFFICES AND TEST ROOMS.

At the east end of the buildings are commodious offices and switch and test rooms. The switchroom, in which all the electrical connections converge, is fitted with a very complete set of instruments for controlling the current and regulating its distribution between the several circuits. The three Lowrie-Parker alternating current dynamos (of 150 units each) are connected by separate leads with the private lighting switchboard, so that any one of them can be run on either of the two mains. The arrangements also permit of the machines being run parallel, and a special synchronising board is provided for this purpose.

It may be interesting to here give a few particulars of this method of running the alternators. The mains from the alternators are first brought to safety fuses in the switchboard, arranged so that a fuse can be instantly replaced without stopping the dynamo, and by a system of four break switches, any dynamo can be put in communication with any circuit or circuits, or the whole of the dynamos be put in parallel circuit. Besides these mains conveying

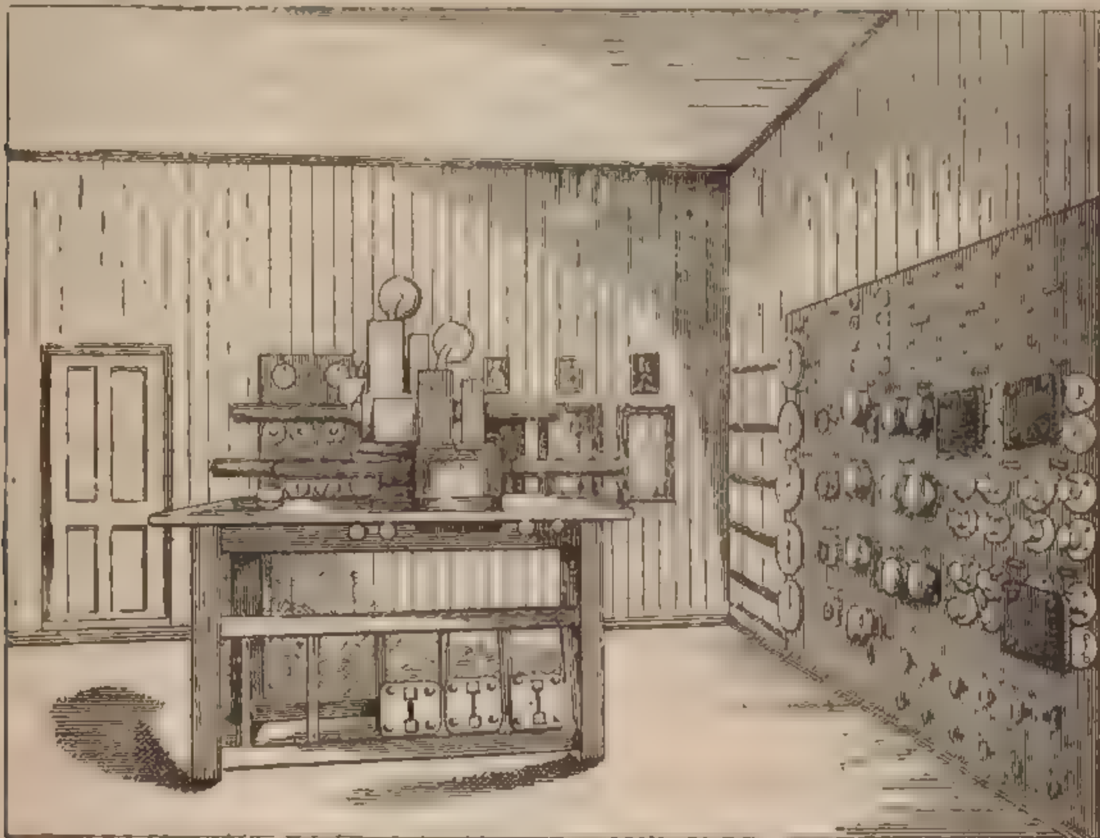

FIG. 5. Switch Room, Dublin Central Station.

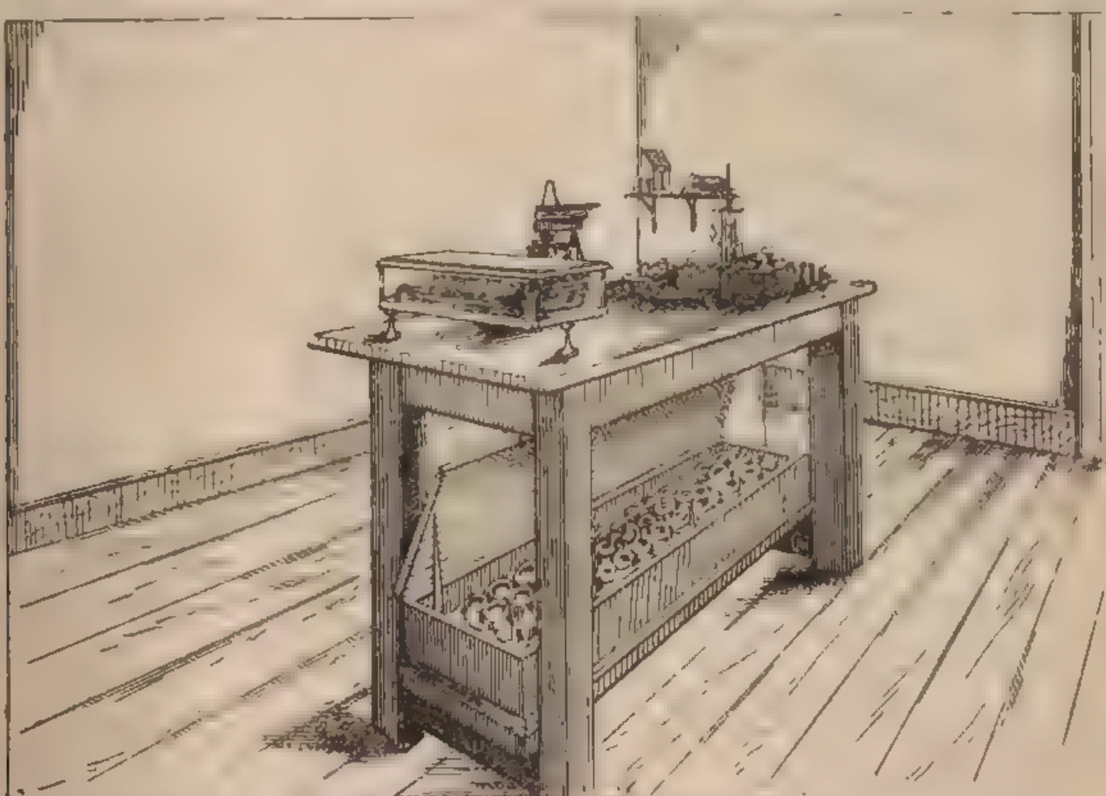

FIG. 6. Test Room, Dublin Central Station.

the entire E.M.F. of the dynamo, a small wire placed across one coil of the armature is also brought to the switchroom; this is for measuring the voltage, synchronising, and for regulating the pressure. Each coil being similar, the measure of one coil is a direct proportion of the whole, and entirely prevents any inaccuracies that would occur in measuring from a transformer. A simple current meter is also included on the switchboard to indicate to the attendant approximately the current given out by each dynamo. When the maximum safe load of any dynamo is reached, the attendant can either put in another machine parallel, or put one of the circuits on some lighter loaded dynamo if working independently. The synchronising is effected through the one-coil circuit; for instance, if one machine shows by the indicator that the load is approaching the normal, and another plant is started, a small switch places the second machine parallel with the first machine, though one lamp only is placed on the synchronising board. When the phases of the two dynamos correspond, the lamp is steady and bright, but not until then. The second machine is then instantly put in parallel with the first by the insertion of one main switch, and at once takes half the load. The slightest inclination of one plant to get out of pulse with the other throws the majority of the work on the faster engine, and reduces its speed, so that one plant entirely controls the other. The regulation is also done from the single coil current, a small converter being interposed between it and the regulator to ensure the attendant from any shocks that might occur from a fault on the circuits or dynamo. It is a very simple, inexpensive piece of machinery, only having to convert a low tension to another about equal.

A complete set of voltmeters and ammeters are provided, the former being of the well known Cardew type. A hand regulator in the form of a variable resistance is placed in the exciter circuits for keeping the voltage constant between the mains. The latter, however, will not as a rule be needed, as three of the Lowrie-Hall patent automatic regulators have been put in connection with the machines. The principle is that of a shunt of varying resistance on the magnets of the exciter. A special feature of the arrangement is found in the main switches. These are made in the shape of four copper plugs attached to a massive block of insulating material with a handle at the back. The plugs fit into porcelain sockets containing brass tubes in connection with the mains, accurately tapered to receive them, and attached to the heavy slate base of the board. A long break is thus made on both poles of the circuit on drawing out the plug handle, and forms a very efficient double-pole switch. The same form of switch is also used in the arc lighting for bringing the dynamos in connection with the three circuits into which the streets are divided. Similar porcelain sockets are also made use of, not only for the switch plugs but also for smaller plugs, to which flexible leads are attached in such a manner that any dynamo can be run on any circuit, or, if it need be, two or three of the circuits can be put in series by simply changing their positions in the sockets.

Automatic regulators of the Brush Geipel type are put in conjunction with each of the arc lighting machines, and serve to maintain a very constant pressure in the mains, and there is thus very little flickering of the lamps. The principle upon which they work is a shunt on the field-magnet circuit of the machines, the excitation of which is modified so as to always maintain the most suitable current in the lamps.

All the instruments for both public and private lighting, with the exception of the automatic regulators, are fixed to the large polished slate bases mentioned above, supported by a strong wooden framework, which forms two sides of the room. Between this framework and the brick wall of the building is a passage of about 3ft. wide, with a trench containing the cables running to the street and dynamos; and from these all the necessary connections to the instruments are made and can always be readily inspected.

THE SYSTEM OF MAINS.

The system of mains for distributing the current in connection with the station is that of the Lowrie-Hall patent. The mains are laid underground, chiefly below the pavements, and consist of lines of cast-iron culverts and boxes, into which the cables are drawn. Various sizes of pipes are used, from 3in. to 6in. in diameter, while the patent Lowrie-Hall surface-boxes are made on the interchangeable system, and are suited to any size pipe, these being placed in the street at a distance of about 70 yards apart. By the aid of these boxes the cables can be easily drawn out and inspected for repairs, if necessary, without any interference to the street from box to box. The pressure on the mains which will convey the electricity to the public street lamps will reach a maximum of 3,000 volts, while the current for lighting up private houses will be transmitted from the dynamo along the cables at the tension of 2,000 volts. Before it enters the houses, however, it is reduced by means of the Lowrie-Hall transformer to a perfectly innocuous current of 100 volts. The wires in the houses will, of course, be highly insulated, but it will be reassuring to nervous persons to know that a contact with a current of this tension, though perhaps it would give a slight shock, is quite harmless and would endanger neither life nor limb.

The transformers used are the Lowrie-Hall patent, and are specially made by the Leeds and London Electrical Engineering Company, Limited, while the meters, which will register the amount of current used by the consumers, are of the Schallenberger type.

At present only the following streets will be lighted by electricity: Grafton street, College-green, Dame-street, Parliament-street, Capel street, Mary street, Henry-street, Sackville street, D'Olier-street, College street, and Westmoreland street. In these streets are erected 78 lampposts, reaching to the height of about 23ft. The lamps themselves are the Brockie Pell patent, recognised for its steadiness and reliability. The light given equals about 2,000 c.p. The testing apparatus consists of a Wheatstone bridge in conjunction with a highly sensitive galvanometer of the Sir William Thomson type, with the usual complement of shunts, a massive reversing, and a large battery of Leclanché cells giving about 115 volts pressure. Most of the instruments in regular use are attached to a table in the test-room of special design with the connections marked upon the top. The galvanometer stands upon a granite column, sunk some 12ft. into the ground to the surface of a hard gravel stratum, the object being to protect the instrument from any vibration which would necessarily interfere with its readings. A complete set of apparatus for re-standardising any of the instruments used in the station is also provided in the shape of a standard current balance, an electrostatic voltmeter, and rheostat resistance, all of the Sir William Thomson pattern. If necessary, the house meters can also be readily tested and recalibrated by means of these instruments. Altogether the testing rooms are fully equipped with the latest patterns of instruments connected with the practice of electric light supply.

The method of testing the insulation of the mains is to take a circuit when the current can be conveniently stopped each day, and then test for insulation with the Thomson deflecting galvanometer and Wheatstone Bridge. This, in a continuous supply, was known to be defective, so a novel and simple instrument has been devised that shows at a glance, and, if necessary, records, any change of insulation in the cables. The instrument used consists of a small box containing a vacuum discharge tube provided with sight-holes. One terminal of the tube is connected to earth, while the other is put to the cable which it is desired to test. If the insulation is good there is a glow in the tube due to the static charge in the conductor, but if there is any defect in the insulation this glow is diminished according to any earth connection which exists. Should any circuit get dangerously low in resistance to earth it is stopped at a convenient time either night or day, and the fault localised and removed in the ordinary manner. By the use of this continuous recorder, a defect can be remedied before it has gone so far as to cause a breakdown, and as all the underground work is very high-class the risk of a defect arising is extremely small.

We have now fully described all the apparatus in use at the central station, and have only to add that it is the universal opinion of the engineers and electricians who have visited the works that it is one of the finest and most complete electric light supply stations in the United Kingdom.

It will be remembered that last year the Dublin Corporation accepted the tender of the Electrical Engineering Company of Ireland to carry out the central station installation. This company had arranged with Messrs. Hammond and Co. for the work of construction, and the latter company has now furnished the installation, a description of which is given above. Mr. E. Manville has acted as consulting engineer to the Corporation, while the immediate supervision of the work has been under Mr. Spencer Harty, the city surveyor, assisted by Mr Ruddle, clerk of the works. Mr. Robert Hammond has personally given a good deal of attention to this work, and was resident in Dublin for a considerable time towards its completion; while Mr. Charles J. Hall and Mr. J. W. Chisholm, of Hammond and Co., have been testing the machinery, and under these gentlemen, the work has progressed in a very satisfactory manner.

ENGINEERS' STORES.

A laundry exhibition is hardly the place where an enquiring mind would expect to find any very novel assortment of stores for engineering shops and central stations. Yet so it is, and at the exhibition now being held at the Central Hall, Holborn, a very creditable show indeed is made by the firm of George Skudder and Co., of 98, Tooley-street. This firm, we find on inquiry, has been established 35 years, and is now in the hands of the two sons of the founder, who actively carry on an extensive trade in asbestos packing of their own manufacture, lubricating oils of their own refining, belts of their own tanning, and stores of various other kinds, produced from their works at Rotherhithe.

A clean and wholesome looking oil, their "B I" lubricating oil, is the principal and most prominent article. This is greatly used for dynamo work at many installations in and around London, amongst others by the famous installations at Messrs. Pears, of "Pears' Soap," and many of the London banks, who nearly all have installations of their own nowadays. This oil is, of course, useful for all kinds of machinery, and the machinery at the exhibition, driven by Hindley's engine, is lubricated therewith.

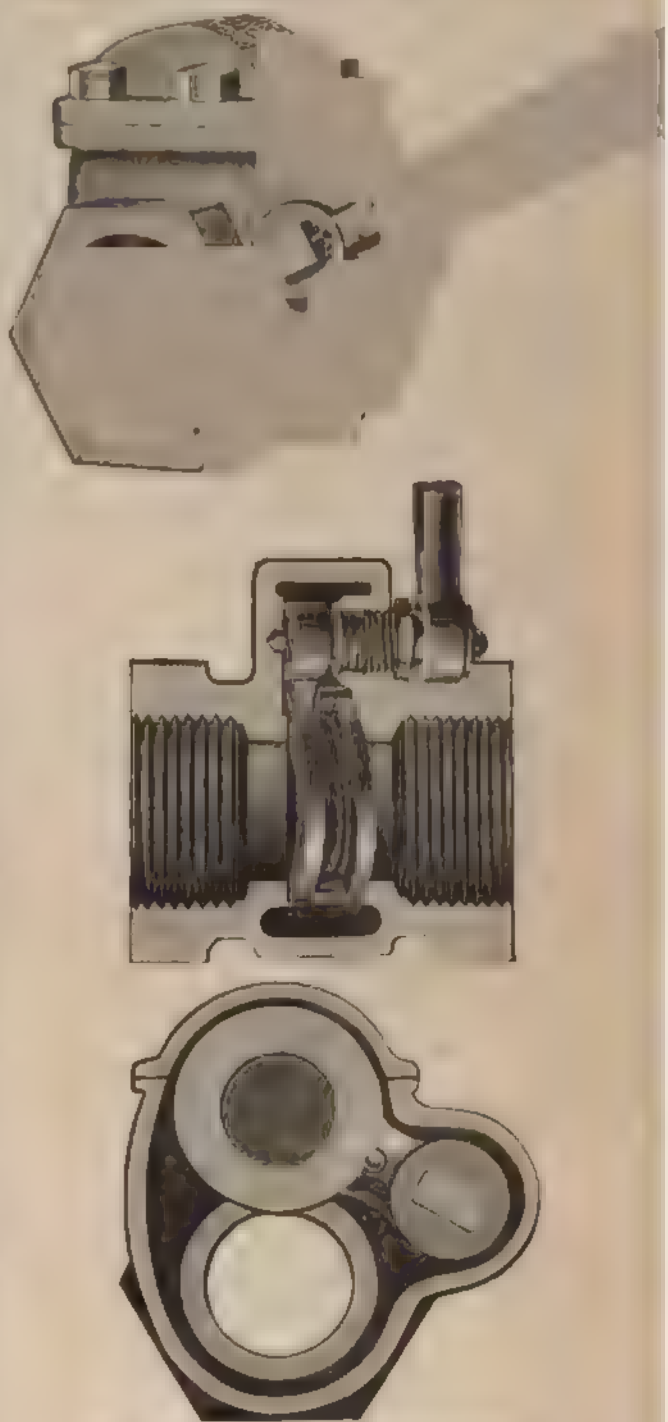
The next article is the "B I" cylinder oil for the cylinders of steam engines—a heavier article; and a third is a special gas engine oil, a fine oil, with a large proportion of lard oil in it, having a high flashing point.

With regard to packing, some interesting samples are made by Messrs. Skudder. They own a half share in a Canadian asbestos mine, and manufacture their packing direct. Rope packing and block packing for pistons, tape for manhole joints, and other sorts and sizes are shown, and asbestos cloth is not forgotten. The ordinary sponge cloths, dear to the heart (and hands) of the dynamo tender and engine man, are here in abundance, white and fluffy, ready to soak up the grease.

An exceedingly useful piece of commodity in engineering works is a removable steam pipe covering produced by Messrs. Skudder and Co. The ordinary steam pipe covering is rather difficult to displace, once it is fixed in position, but by means of making it slightly flexible and in short lengths, and of having a straight joint down one side, attachable by clinching nails, this covering can be removed with the greatest ease whenever repairs or alterations of steam pipes are to be done. This covering is made in different qualities, from the common brown paper up to highly incombustible and non-conducting material for high-pressure pipes. Amongst the other stores on view are to be seen tube and flue brushes, made excellently well with twisted spirals of steel—warranted to last for years of use—and the new patent metallic tubing, here shown applied to a variety of uses, and adjusted to be easily connected together in various lengths.

There is a peculiarly useful thing in steam valves, called the handy valve. Instead of having the ordinary milled wheel for turning by hand, difficult to deal with when, as sometimes happens, the valve is up in the roof, these handy valves have an arm to work the steam passage, and this is moved by a cord or rather a couple of cords, one for turning on and the other off. The action is easy and efficient, the position of the arm showing the extent of the opening, and it makes a very useful variation of steam valve for an engine-room where trouble is desired to be saved, and where the pressures are not over 100lb. to the square inch.

Sight feed lubricators for dynamos are not forgotten. A very neat type of lubricator is shown. It can be regulated from one up to fifty drops per minute; the oil can be seen dropping, and when the machine stops a little turn-up tap cuts off the supply so that there is no waste, and the trouble of attention is a minimum.



The "Handy" Straightway Valve, worked with Cords.

Besides these things, Messrs. Skudder and Co. exhibit a number of excellent belts of various material. A special kind adapted for dynamos is their raw hide belt. These are cut with the grain of the leather, and are not tanned, but heated chemically for about four hours. They are said to last longer than tanned belts. A 10in. raw hide belt, which was on view, has been sold for driving a dynamo in the North of England. Tanned leather belts of excellent quality are also shown, as well as a number of camel hair belts. These latter are very pliable, and are recommended for exposed and damp situations, or for open air work generally. The whole exhibit by Messrs. Skudder and Co. is very interesting from an engineer's point of view.

THE TELEGRAPH BILL AND TELEPHONES.

Two or three things have for the moment directed renewed attention to telephony in connection with telegraphy. There are in the first place the letters of the Duke of Marlborough and General Webber to the *Times* last week. The first of these is an exceedingly clever production from an exceedingly clever man—inasmuch as it is an excuse for what many would call a retrograde movement. The Duke and his colleagues, the promoters of the New Telephone Company, started a crusade against the men in possession, and up to a point seemed about to carry off the honours of war. A large number of telephone subscribers, in London at any rate, attracted it may be by the promise of cheaper rates and a better service, signed on to the New Company. When affairs were ripe and the prospectus was issued we were all surprised to find our old friends—or if you prefer it our old enemies—pulling the controlling wires. The situation is a queer one, but it has to be faced. To the ordinary onlooker what will happen is this: the New Company will hand over the work to be done to the already organised company and its staff of workmen. New twin-wire connections will be made by the old company's staff, and gradually the whole London system will become a twin-wire system. The combined boards will be found inconvenient, amalgamation will take place, and the ultimate board will consist of those who are cleverest in making their power felt. The Duke of Marlborough had two things to consider in his letter, at least, two important questions; the first was to point out the dangers of competition—dangers which had not occurred to him till he had gained his point and position—then he had to play for a fall as to rates. The New Company's subscribers have signed on under certain rates and conditions. It is evident there will be an attempt to modify these conditions. This is gathered from the sentence "As to the matter of rates, this question produces some difficulty to determine *at present* (the italics are ours), owing to the Government having established a system of telephone uses which will necessitate sound consideration on the part of the companies before establishing their new scale of charges." But the National Company was in the position of being able to modify its charges owing to the new conditions—those charges having been arranged under old conditions, while the New Company's proposed charges were made having the new condition of things in mind, and, in fact, while advocating the Government taking the trunk lines. To us it seems that a combination of interests having been effected, the New Company will go back on its promises, and a scale of charges higher than those contemplated three months ago will be brought into force three months hence. Under the circumstances, we have no hesitation in saying that no single subscriber is legally bound by having signed a requisition to the New—that is, if the latter change their promised plans. We frankly acknowledge that we have been completely bamboozled by the action of the New Company, because the outlook at the commencement of their work seemed to point to "efficiency with economy."

As things have turned out, there is no certainty of either. It is well known, however, that our sympathies have always been in the direction of a government monopoly, and we only accepted the competition of the New Company as a *pis aller*. We are as convinced as ever that the Government ought to, and in the long run must, take over the telephones. The combined interests know this as well as anybody, but they are in this unique position, they can hurry up or delay Government action at their own sweet will. If they give us an efficient and economical service their years of existence are very short, because such a service means so large an increase of subscribers that the telegraph return must suffer considerably, and too much public money is locked up in the telegraphs to allow too great a loss. If, however, the telephone service is but moderately good, the telegraph service will just go on paying its way without interest on capital, while year by year the capital expenditure necessary to take over the telephones will increase, and thus induce Postmasters-General, Chancellors of the Exchequer, and Governments, to put off the evil day.

We have left ourselves but scant room to call attention to the special report and report of the Select Committee on the Telegraphs Bill, which together with the minutes of evidence has just been issued. The cost of report and evidence is only fourpence, so that anyone interested in the subject can easily obtain a copy. One or two of the questions relating to the future action of the department were of an insidious character. Mr. Summers suggested that taking over the trunk lines made it evident that the Post Office thinks it desirable the State should take over the telephonic system, to which Mr. Lamb did not disagree, nor to the suggestion of Mr. Shaw Lefevre that taking over the trunk lines was a long step towards the ultimate end. The evidence of Mr. Lamb before the Committee shows that the permanent officials regard telephonic competition as partly at any rate accounting for the falling off in telegraphy. Our argument has always been that if the amount of royalties paid by telephones equalled the estimated rate of increase that should be received from telegraphs, the Government might well hold their hand. Mr. Lamb, in his evidence, said the amount paid on royalties was "A little more than £40,000 for the last year." He gave the gross figures of the revenue of the telegraph department for the year up to March, 1892, as £2,542,200. Mr. J. Staats Forbes in his evidence gave the number of telephone messages as 160,000,000, "at an average cost to the public of a little over one halfpenny for each communication." Say the 160,000,000 verbal messages brought £350,000, which is little over halfpenny per message. Out of this the Government got a little over £40,000. We contend that through not working the telephone system and getting only royalty, the Government lost at least another £40,000, and will continue to lose this and more every year. In the long run some government will be forced to buy the telephone system at a ruinous loss, for telephony having then practically superseded ordinary telegraphy, the capital spent on acquiring the telegraphs must be added to the capital spent on acquiring the telephonic system, or the nation will have to put down the millions spent in acquiring the old telegraph system for which they have received little interest as lost—a not very pleasant prospect.

REVIEWS.

"Electric Lighting for Marine Engineers," by SYDNEY F. WALKER, M.I.E.E., Tower Publishing Company, London.

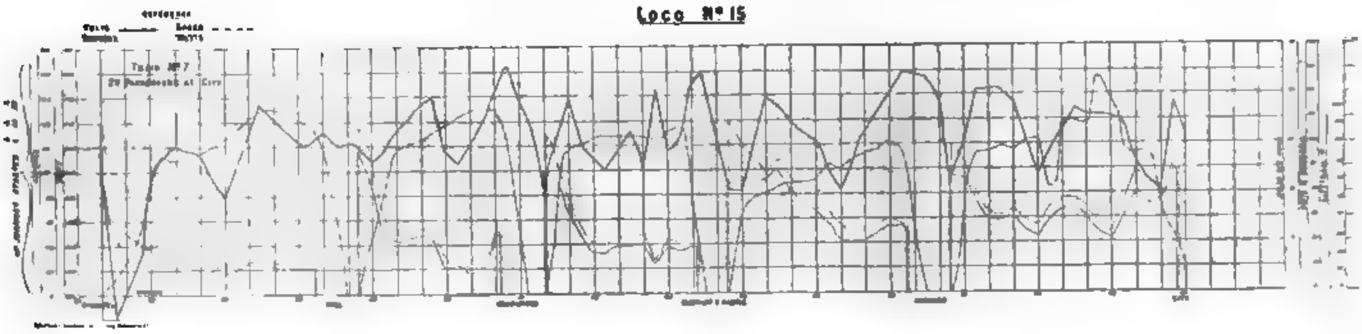
This is a special book with a special object—viz., to instruct marine engineers in the rudiments of electrical work. It is necessary for completeness and for lucidity to give a good deal of information in such books as bears upon the subject generally, and not upon the one branch specially. In this last decade of the nineteenth century we must complain when a book is issued without an index. The table of contents may be full, as in this case, but an index is always required. The book before us is written in a manner and with a method that should commend itself to readers. The preliminary chapters deal with the terms used in considering the subject, with dynamo machines, with cables, wires and wiring, lamps and fittings, switches and cut-outs, and the various details connected with these subjects, as well as with measuring instruments. We imagine, however, that the chapters on faults, or causes of failure and how to remedy them, the use of electric light on petroleum ships and on cargo ships, as well as the information about search lights, will be most appreciated by the class for whom the work is specially written. As a rule, the marine engineer takes charge of the complete installation, and has nothing to do with the actual work of installing the plant, though, of course, in order to maintain it properly it is best to have some idea of the whole work. It is becoming common now to have a spare armature in case anything goes wrong with that originally in the dynamo. In his chapter on "Faults, etc.," which may be taken as a sample of the whole book, the author commences by pointing out the faults likely to arise, and how they may arise. We have then the search, the finding the fault, and when possible the method of remedy. With regard to the safety of the electric light on board petroleum ships, we take it that it is agreed that no light can be absolutely safe, but that the electric light properly installed and carefully maintained is safer than any other illuminant. We believe the marine engineer will welcome this book.

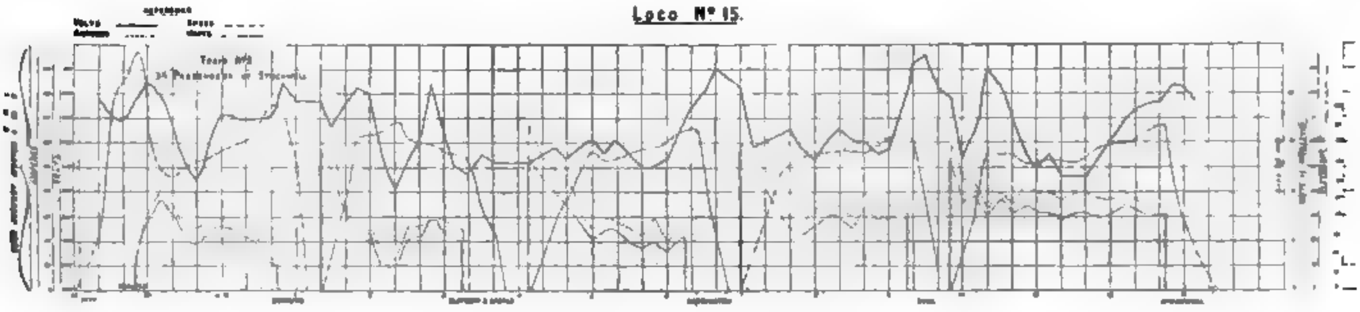
VENTILATION OF BILLIARD SALOONS.

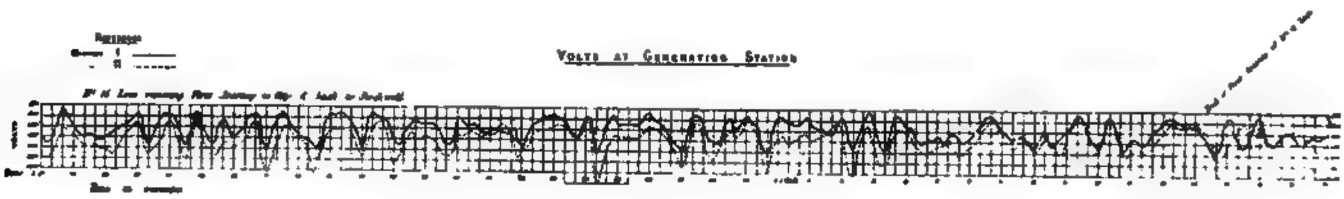
The beneficial results and usefulness appertaining to this branch of the electrical industry is one of such considerable importance, not only to central station managers (desirous of increasing revenue account), but also to the proprietors of billiard saloons, as well as to their customers desirous of playing in a healthy and purer atmosphere, therefore, under these circumstances, we take pleasure in calling special attention to a new alternating current electric blower, which is being placed upon the market by Messrs. Shippey Bros., who are now so well known in connection with small motor work.

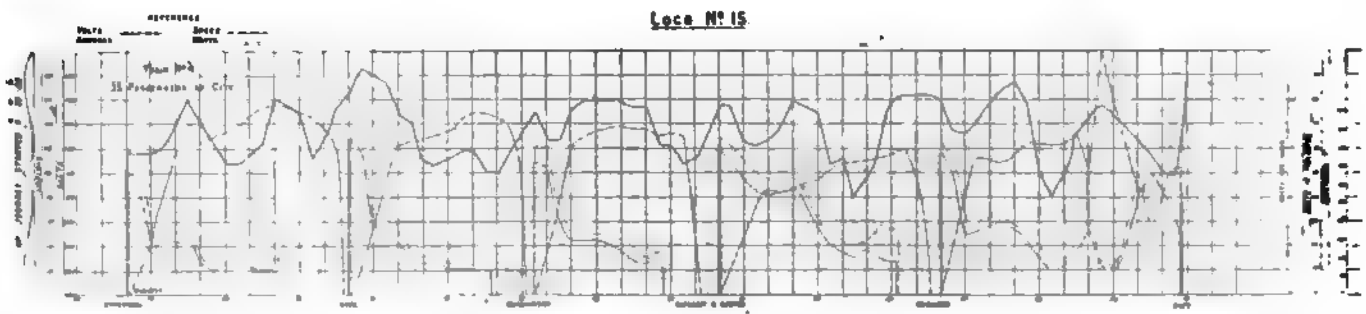
It has come within our province to recently inspect one of these new type of electric ventilators, which appliance has been specially designed by Mr. Arthur Shippey, in order to carry out the objects in view. The revolving fan is entirely enclosed in an outer case, and is arranged for fixing either to or outside of the walls or windows of billiard saloons, smoke-rooms, etc., and by a specially-constructed switch the brushes can be easily reversed by pulling a chain, so that it can be either used as an exhauster of foul air or utilised to suck in fresh air according to requirements. The one submitted to our inspection has been specially constructed to work on alternating currents, and is supplied in three useful sizes of 12in., 18in., and 24in. blades, and in three windings to suit the leading alternating current systems at present in vogue in this country and abroad. The motor has self-oiling bearings, and is also fitted with an

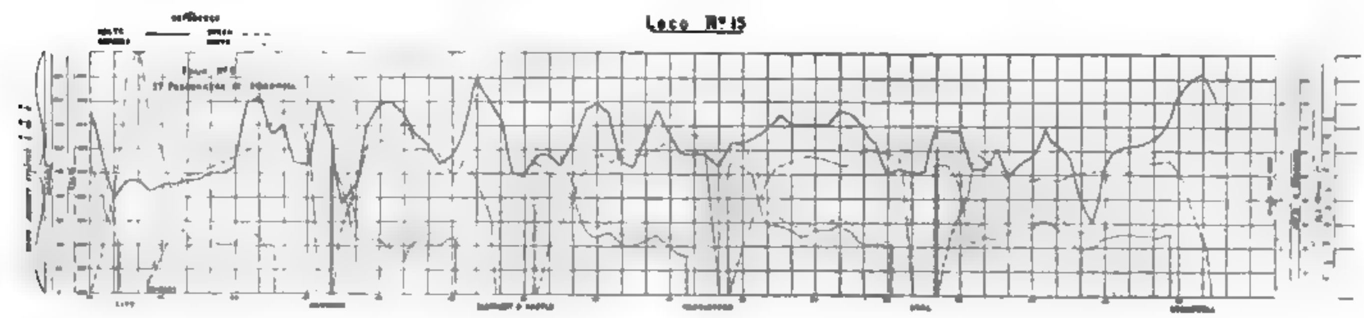
ingenious arrangement for constantly cleaning the commutators from dust, etc., a plan which greatly tends to prevent sparking and the wearing away of same. We have not tested the efficiency or actual working results, but are told they are good. However, we are promised a ventilator for this purpose very shortly, when we shall take the opportunity to place before our readers fuller particulars and drawings of this ingenious little appliance, which is well made and has every appearance of doing good work, and one which we think is destined to assist in the sale of electricity, especially in districts where current is obtainable at a reasonable price.

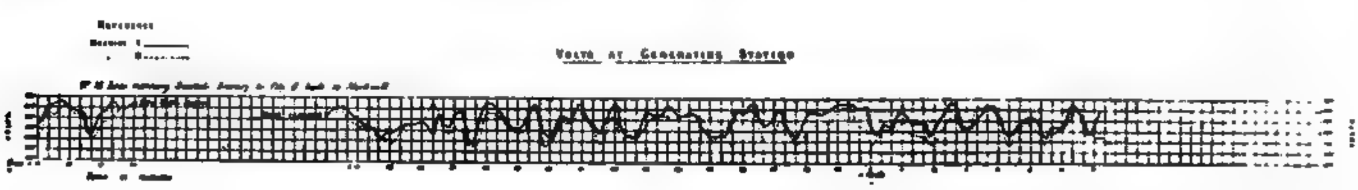






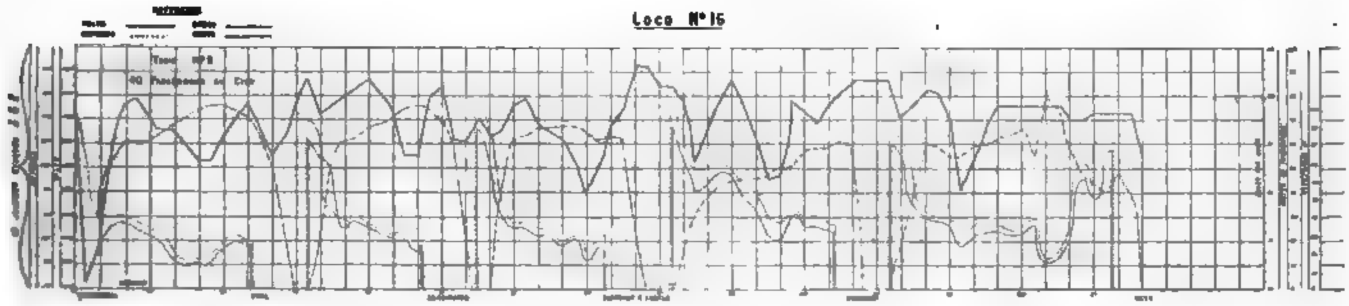


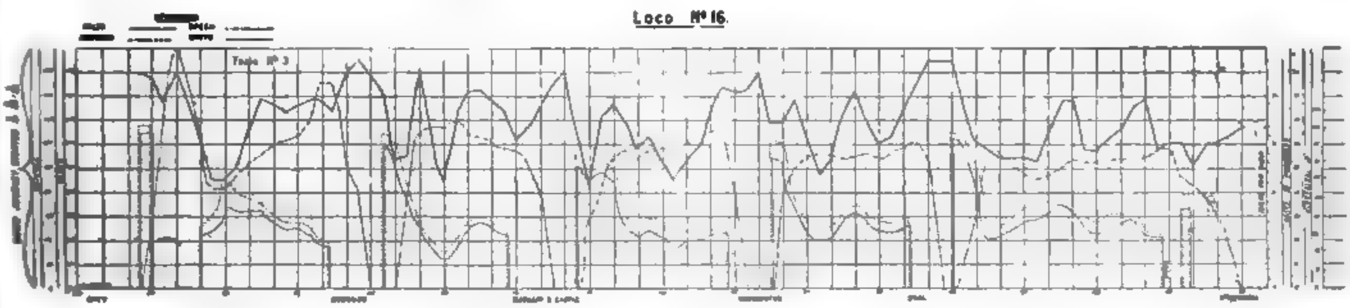


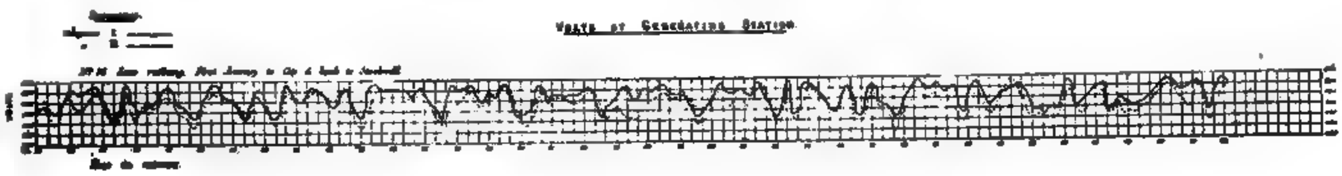


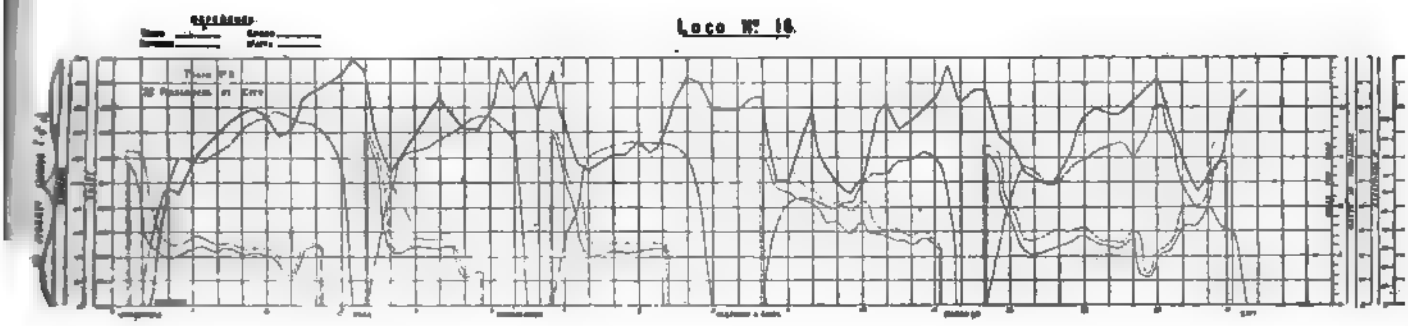
ELECTRIC LOCOMOTION: SOME RESULTS IN ACTUAL WORKING.

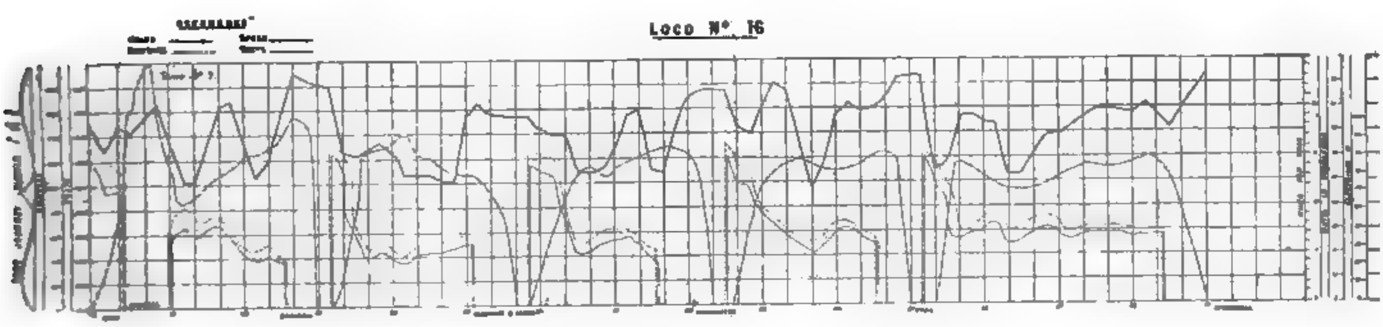
BY ALEXANDER SIEMENS.

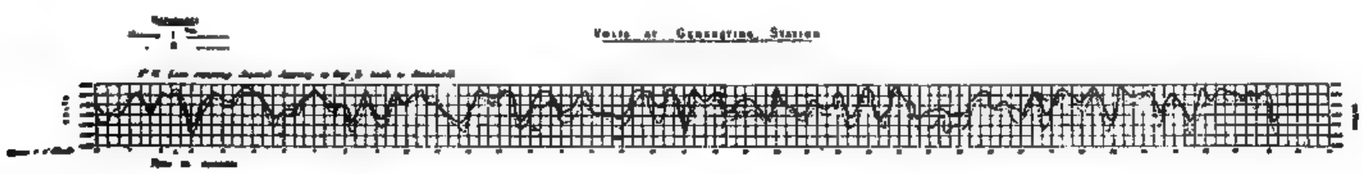












Owing to an oversight the curves were omitted which illustrated Mr. Alexander Siemens' paper, as given in our issue of August 12, and which was read before the British Association at Edinburgh. We now give them on this and opposite page, so that our readers may have the paper complete.

LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

I.—EVOLUTION OF ELECTRICAL ENGINEERING.

THE FIRST ELECTRIC LIGHT.

It was on one evening in the year 1810 that Sir Humphrey Davy showed to a large and distinguished audience, assembled at the rooms of the Royal Institution, the brilliant and dazzling light that was produced by passing a current of electricity through two pencils of charcoal, about an inch long and one-sixteenth of an inch thick, the said pencils being placed end to end, and slightly separated from each other. This is generally conceded to have been the first time that the world saw the electric light, hence we may date its birth from the above historical event.

DISCOVERY OF DYNAMIC ELECTRICITY.

In those days the only available source of electricity was the primary or voltaic cell, and to obtain any large quantity of electricity a great number of these had to be used. A number of cells connected together forms a battery, probably so named after the example afforded by calling a number of field-guns a battery. The battery employed by Sir Humphrey Davy consisted of 2,000 Grove cells, so some idea can be formed of the great trouble and expense incurred in handling such a quantity. A voltaic cell, as most people know, consists of two different metals put into a glass or porcelain jar, the jar being divided by a porous partition, and filled with acidulated solutions. A wire is fixed to each metal plate, and when the two free ends of the two wires are joined together, so as to form a complete circuit, then a current of electricity will flow, the strength of which will depend on the size and nature of the metals, and the kind of solution, etc. In the particular type of cell, known as Grove's cell, the two metals consist of zinc and platinum, the zinc being put into a solution of sulphuric acid and the platinum into a solution of nitric acid.

It was reserved to the genius of Henry and Faraday, those two seekers after truth, to disclose to the world the great discovery that magnetism could produce electricity a discovery that is justly classed as one of the most important that man ever made.

The honour is equally divided between the two above-named men, each was working patiently and laboriously to find the link between electricity and magnetism—Henry in the New World, amidst his busy work-a-day duties of teaching at Albany Academy, New York State, snatching, when he could, a few spare moments to spend on his absorbing experiments. Faraday, in England, with ample leisure and scientific facilities of every description at his command, occupying, as he did, the position of chemical professor at the Royal Institution. Each was working independently of the other, and made the long wished for discovery independently. In point of time Henry was the first to reach the goal, August, 1830, being given as the time of his decisive experimental proof, while Faraday arrived at the same ends in September, 1831, ignorant of Henry's work.

And now to set forth the nature of this momentous discovery. Prior to this time it was known that when a current of electricity was flowing in a conductor or wire it would deflect the needle of a compass placed near to the wire, showing that the electric current acted magnetically by deflecting or attracting the needle Henry and Faraday discovered the converse of this, i.e., that magnetism could produce an electric current. When a piece of iron is magnetised its two ends are named the "poles", when the iron bar is bent into the shape of a horseshoe its two ends are brought near together, so that both the poles can exert their power jointly, from one pole of the magnet a stream of what has been named by Faraday "lines of force" issue, and re-enter at the other pole, in the case of the horseshaped magnet, the lines curve across the air gap between the two poles, and the space which these lines of force occupy is named the "magnetic field" these lines of force, of course, are only imaginary, like the Equatorial line, but they serve to illustrate very clearly the direction of the magnetic forces. When the ends of the magnet do not face each other the lines curve round in issuing and entering. If a length of wire or metal conductor, whose two ends are joined so as to make a complete circuit, be caused to move across the magnetic field, so as to cut through, so to speak, the "lines of force," then a current of electricity will be generated in that conductor, and will last so long as the movement of the conductor lasts in the magnetic field. The same effect will be produced if the wire is stationary and the magnet be caused to move. This, then, in brief, is the fundamental principle upon which all dynamos work, and without the possession of this it is safe to say there would be no electric lighting as it is to-day.

EVOLUTION OF THE MODERN DYNAMO AND LAMPS.

For some considerable time the dynamo was confined to the laboratory, and looked upon as a scientific piece of apparatus, scientists little dreaming what a future it had before it. The first practical form which the dynamo assumed was that brought out by Dr. Werner Siemens in 1867, and during the subsequent 10 years many keen minds were hard at work improving it, and gradually bringing it into shape, electrically and mechanically.

Naturally the next article that claims our attention is the electric lamp, the adjunct to the dynamo, the evolution of which was slow and gradual, like the dynamo When a current of electricity is passed through two pencils of charcoal or carbon, slightly separated, these slowly consume away, and the carbons used to be fed forward by hand, this primitive method was supplanted by automatic feeding, effected by clockwork. The first arc lamp of real practical value was designed in 1857 by Serrin, who caused the electric current to regulate the lamp automatically. After this rapid improvements appeared, resulting in the excellent types of to-day.

Turning now to the glow or incandescent lamp, early experimentalists first used platinum wire sealed in a glass bulb, filled with non-combustible vapour. Upon sending a current through a thin piece of metal of high resistance, like platinum or iridium, it is raised to a white heat, the brilliancy or intensity of the light emitted depending on the quantity of current, this is the principle of the incandescent lamp, and since the metal would consume away in the atmosphere it was necessary to place it in a non-combustible vapour, such as nitrogen. Through the invention of the air pump, however, a new field presented itself About 1878 Prof W Crookes made a series of valuable experiments on the vacuum tube, and conceived the idea of making incandescent lamps by placing the thin metal thread or filament in a glass bulb exhausted of air

Simultaneously, we had Edison working in America, and Lane Fox and Swan in England, each striving to evolve a practical glow lamp, each was successful, and at about the same time. Edison and Swan put the fruits of their labour together, and then was created the famous Edison-Swan lamp, consisting of a thin curled thread of carbon sealed in an air-exhausted glass bulb.

ELECTRIC LIGHT MANIA OF 1881.

We now reach the year 1881. An electrical exhibition at Paris, and a subsequent one at the Crystal Palace in the following year, gave the public opportunities of examining and criticising the new illuminant. Mind, at that time there were no self-regulating devices, no proved method of distributing the electric current, no arc lamp that could be counted on to burn for five minutes without spluttering and going out, no serviceable storage battery and lastly, no expression of surprise if the lights suddenly went out at any moment. The dynamo was in a very crude state, the same with the arc lamp, and very little knowledge existed in fixing wires but all this the general public could not see, and at that time the electricians did not either. If the public, and those interested in showing that public how to make its fortune in a day had left the electric light alone, all might have gone well, but the financial wolf was abroad in the guise of the company promoter, seeking whom he might devour Due probably to the success that had attended the pioneers of electric lighting, the most exaggerated and chimerical notions were spread abroad as to the miraculous feats electricity was going to perform, a mania arose, companies were formed by the dozen, the gulled public bought shares expecting to make

their fortune, gas was looked upon as a thing of the past, and a temporary panic was felt in that quarter. Electricity was going to be used universally, and to supersede gas entirely, and shares in these bogus companies rose rapidly. In fact, the public were blinded by the dazzling effect of the electric light!

Then came the awakening, the breaking of the bubble, and all the castles in the air vanished, demolished by hard facts; but the disappointment of the public did not vanish quite so quickly; it is remembered to this day. The result of this failure can be easily explained. The electric light was only a laboratory experiment then, and everything, as before mentioned, was in a very crude state; particularly, suitable apparatus for controlling the light automatically; the compounding of dynamos was unknown, and lights could not be switched off and on in various quantities, unless there was some manual aid to keep the lights at their proper brilliancy.

SUBSEQUENT PROGRESS.

During the last few years invention has been going on at a very rapid rate. The most eminent scientists and physicists of the day have given their minds to the task, and have diligently laboured and experimented in the laboratory. Bit by bit, piece by piece, has the edifice of electrical science been built up. One man's mistake was another man's luck, defects were rooted out one by one, and no sooner was one thing accomplished than another man tried to improve it. The man of science was, however, not sufficiently backed up by practical aid. The early electricians did not exhibit good mechanical construction in their apparatus; they were ignorant of the forces with which they had to deal; in one word, they did not treat electricity as electric horse-power. Dynamos were built too weak; there was no mechanical design about them; a piece of string used to be put where a piece of steel wire is now put. It is now thoroughly understood that a dynamo, or any other electric machine which produces power, must *à priori* be designed and built in a strong and substantial mechanical fashion, just the same as a steam engine is built. The electrical engineers of to-day have taken this to heart very thoroughly, for their education and training requires a good knowledge of mechanics as well as of electricity.

It may in truth be stated that the latter half of the Nineteenth century will be famous as "The Electric Age," and will mark the development and application of a new and mysterious force, which has been tamed and harnessed through the indomitable energy of man to a thousand and one uses, benefiting all humanity. A force which does its work silently and swiftly, yet giving no sign of its presence; a force subject to the greatest elasticity in division and sub-division; and a force which in process of time will probably be called upon to be the universal slave of mankind, ready at a moment's notice to do his bidding, by land or sea, in the toiling city, or in the solitude of nature; another secret wrested from nature, signalising another triumph of mind over matter.

(To be continued.)

THE EFFECT OF FRICTION UPON THE EXACTITUDE OF ELECTRIC METERS.

BY G. P. ROUX.

The question of electric meters becomes every day more and more important as the developments of the distribution of electrical energy increase, but among the numerous systems of meters which have been brought forward, up to the present there are few which have given satisfactory results.

As in every mechanical apparatus set in motion by any means whatever, there are necessarily in every electrical meter rubbing contacts and friction. The friction arises from a number of causes—want of oil, bad lubrication, dust, abnormal expansion of certain parts, inconstant resistances of the dial wheels, resistances produced by the air upon certain pieces in rotation, friction of brushes and pivots, wear and tear, and so forth.

By reason of their very nature these frictions are not constant, and vary from day to day even in the best constructed instruments. They can in no case be considered as invariable, whatever may be the ingenious arrangements employed in the construction of pivots, gearings, etc. They may be reduced, but they cannot be guaranteed constant.

In the construction of electric meters sufficient attention unfortunately has not been paid to this important factor—the variation of friction.

Without examining in detail the solutions proposed, I will in a few words breifly describe the different electrical principles which have been employed in the construction of electric meters.

The product to be measured is the electrical energy expended in any circuit and in a given time, which may be expressed thus: E, I, T (volts, amperes, time). It is supposed in certain instruments that one of the factors, E or I, remains constant, according to the circumstances, and the measurement is carried out on E T or I T only, according to whether the distribution is at constant potential or constant current, the first case being the more generally employed.

Meters measuring energy must always be taken as the most exact as taking into account the variation of all the factors, E, I, and T.

A single class of meters are capable in theory of measuring directly and surely the quantity I T of electricity passing through them. These are the chemical meters, the first kind of meter, I think, ever constructed.

These meters are composed of an electrolytic bath, through which is passed either the whole of the current to be measured, or a certain portion taken in shunt from the extremities of a constant resistance. This latter arrangement has been employed by Edison, but if it has the merit of excluding all mechanical movements, its use is very inconvenient and its accuracy more than doubtful. The reading of the meter takes place by measuring the change of weight of the electrodes. This weight evidently represents the quantity of current which has passed through the meter, but the relation of this quantity to the total current is absolutely unknown, because of the variation of the resistance of the liquid in the electrolytic bath, its counter E.M.F., etc.

There has recently appeared another chemical meter, that of MM. Desruelles and Chauvin, which is traversed by the whole of the current to be measured. The electrodes, which are of large surface, are mounted upon a kind of balance beam which, by means of suitable mechanical and electrical arrangements, is made to reverse the current in the meter each time the weight of the electrodes varies by a determined quantity. The gear of the registering apparatus is advanced one place at each oscillation.

We may object in this meter to its complication, which is considerable, and to the certain destruction of the plates at a more or less distant time, and also to the loss of electrical pressure it necessarily produces in the mains by reason of the counter E.M.F. of decomposition, which must at least attain to one volt.

Pass now to the mechanical meters. These may be classed into two large distinct categories: discontinuous integration meters, and continuous integration meters.

The first, of which there are a large number, are composed essentially of a measuring apparatus (voltmeter, ampere-meter, wattmeter) arranged on the circuit to be measured, and a clockwork movement, coming into play at regular intervals to move the gear of a dial counter a certain extent, according to the deviation of the measuring instrument, and rendered, by means of suitable arrangements, proportional to the current.

These instruments are capable of a high degree of precision, but their mechanical complication is almost always very great. Their gravest defect arises from the fact that the clockwork and consequently all the gear and parts of the meter are set in movement as soon as the circuit is connected, even when there is no consumption to be measured. The wear and tear is, therefore, very great, and the instrument requires considerable attention to keep it in working order. The continuous integration meters, or motor meters, are based upon an entirely different

principle. They are composed essentially of two parts connected firmly together: (1) some kind of motor traversed by the current, E I, to be measured, arranged so as to produce a motor couple, K C, proportional to this current; (2) some kind of brake—liquid, magnetic, or other—producing a resisting couple, K′ F V, proportional to the speed of the motor.

I will also mention, for the sake of not overlooking it, one meter which does not belong directly to either of the above classes—namely, the Aron meter. This measures the current by the advance made by one clock having an ordinary pendulum, over a second clock whose pendulum is influenced by coils in circuit with the current to be measured. A differential movement indicates directly the expenditure of current. Besides the inconvenience of winding up the clockwork of this meter by hand, its great defect is the practical impossibility of obtaining synchronism of the pendulums when no current is passing, so that the meter continually adds or subtracts when running light. The attempt has been made to remedy this defect by connecting the two pendulums by a loose thread, in the centre of which is hung a small weight of about one gramme, to force them to beat in unison when free. But this arrangement has evidently the effect of preventing the registration of small currents.

The future seeming to be reserved to the motor-meters, let us examine what is influence on the exactitude of this class of motor caused by variation of friction in their gearing.

We have seen, theoretically, that these instruments must take constantly a speed proportional to the current passing through them. We can therefore establish by the following equation the condition of equilibrium of the system, by saying that the quantity of work furnished by the motor is equal to the quantity of work absorbed by the brake and the friction of the apparatus. That is

$$K V C = (K F V) \times V + \phi V.$$

If it is admitted that ϕV is negligible, that is to say, the friction of the instrument is *nil*, we can say

$$K \times C = K' \times F \times V',$$

whence $$C = V \times \frac{K}{K' F};$$

that is, the current is proportional to the speed.

But these motors being very weak, and having to overcome the friction of pivots, brushes, gearing, it results therefrom that the speed of equilibrium is modified to a greater or less extent, by the presence of these accessory resistances, which are themselves susceptible of variation, and which will consequently cause a variation in the factor, ϕV. The factor has, it is admitted, a certain value of which account is taken in the calibration, but what is not allowed for is the modification of this factor from time to time by the working of the instrument.

The foregoing formula, applying to all the motor meters, it is seen that their exactitude is constantly modified and influenced by the variations of the factor, ϕV, and the variations in the calibration may, according to the cases taken, attain to 10, or even as high as 15 per cent.

There exists one meter upon a new principle which escapes this criticism, the only one I believe which does so, I mean the Brillié meter.* M. Brillié in his meter, at the risk of making the apparatus somewhat complicated, has made it his principal aim to solve this problem of friction variation; and it may be said from the result of the numerous tests which have been made, and from the theory and the principle itself upon which this instrument is constructed, that he has thoroughly succeeded.

The problem has been solved in a very simple manner by the complete separation, the absolute independence, of the measuring instrument from the registering apparatus or motor. The electric measuring instrument is not itself a motor, but a simple electro-dynamometer acting merely as a speed regulator to a small motor, which actuates the gearing and dials of the meter. The advantages which result from this arrangement are as follows: (1) There is at disposal, consequent upon the employment of an electro-dynamometer, a strong effort from a small current, it being possible to wind the coil with many turns, and all the turns being in the position of maximum effort with regard to the coils of the fixed coil. (2) The efforts to be overcome by this measuring instrument are reduced to a minimum. (3). The indications of the meter are rendered independent of the friction of the gear in movement, the speed of this latter being regulated by the electro-dynamometer in the same manner as a steam engine is regulated by its governor, the speed being thus rendered entirely independent of the load.

The movable fine wire coil is suspended by a silver wire, sufficiently long and thin for its torsion to be neglected, especially if the small angle of deviation of this coil be considered, as the deviation is of a few degrees only, and the maximum deviation corresponds exactly with the maximum effort exercised by the current. The torsion may be thus considered as negligible, and the movable coil may be considered as suspended freely on the field of force formed by the passage of the current in the main ribbon coil.

We can, therefore, say that the effort a exercised by the quantity of electricity passing is equal to

$$a = (E I) - t,$$

in which a = effort exercised by the product of
E = volts, and I = amperes, and t = opposing torsional force of the silver wire.

We have seen that this effort t may be neglected and considered as nil, being in practice absolutely negligible.

We can, therefore, say

$$a = E I.$$

By the construction of the meter itself and the principle of the wattmeter coil, the friction usually present in the electric meters is *nil*, and in reality does not exist. The variations in friction of the motor part of the apparatus, which is completely separated from the measuring part of the apparatus, cannot possibly have any effect whatever upon the value a, which will be always equal and proportional to E I. Nor can it have any influence upon the registration, as we shall show.

The integration of the quantities of electricity, or, rather, the effort a, is brought about by an electromotor putting in motion on the one hand a train of dial wheels and on the other hand a set of permanent magnets generating Foucault currents in a copper disc.

Numerous experiments carried out upon Foucault currents, produced either by the rotation of a disc in a magnetic field or by the rotation of a magnetic field over a fixed disc, have demonstrated that the effort developed is directly proportional to the speed of rotation. Consequently we can say that the effort b exercised upon the copper disc is equal to

$$b = [V(8 M)] - R_1 \ldots R_n,$$

in which b = effort exercised by the speed, V, of rotation of the magnets possessing a magnetic field, M, their number being eight.

From experience and in view of the special quality of make and the progress realised in the manufacture of magnets, we may consider their magnetic field as remaining constant. The value, 8 M, is therefore constant.

On the other hand, the resistance, $R_1 \ldots R_n$ will alone influence the speed of rotation of the magnets turning under the impulse of the motor, consequently it is the motor alone which will be influenced. Now, as the speed, V, is obtained by the value of the energy, $e\,i$, passing in the motor, we can say therefore:

$$b = (8 M) \times [e\,i - (R_1 + R_2 \ldots R_n)].$$

This granted, we will examine how the system behaves when a variation of friction resistance occurs.

We have seen that the copper disc is connected firmly with the movable coil of the wattmeter, and that the effort exercised upon this latter takes place in an opposite direction to the effort exercised on the copper disc by the rotation of the magnets.

Suppose, now, there is an increase of friction in the gearing or other part, we have seen above that the effect of this would be to diminish the speed of rotation of the magnets, and therefore the value b, consequently the

* A full description, with illustrations, of this meter was given in the *Electrical Engineer* for June 17th, 1892, pp. 596-7.

equilibrium which existed between the two efforts a and b, will be destroyed, and we shall have

$$E\,I > (8\,M) \times [e\,i - (R_1 + R_2 \; . \; . \; . \; R_n)];$$

whence, $a > b$.

The value a being greater than the value b, the movable coil of the wattmeter will deviate under the preponderating action of E I, and will draw with it the regulating resistance of the motor circuit (to which, in the Brillié meter, it is connected), the effect of which will be to increase the current, $e\,i$, passing through the motor, and thereby giving it sufficient power to overcome the increase of friction resistance spoken about; the speed, previously diminished, will now increase until equilibrium is again established—that is, until a is once more equal to b, which will occur when the speed of rotation has returned to its preceding value corresponding to E I.

Let us now take the opposite case—namely, a diminution of friction. The speed will then increase and the effect produced by the rotation upon the copper disc will also increase, and the case will then stand thus—

$$E\,I < (8\,M) \times [e\,i - (R_1 + R_2 \; . \; . \; . \; R_n)],$$

whence, $a < b$.

The value b being now greater than the value a, the wattmeter coil will deviate under the preponderating action of the magnets, and will draw with it the rheostat contacts, will increase the resistance in series with the motor until the increase of resistance having sufficiently decreased the speed, the effort b has returned to its primitive value.

It is seen, therefore, that in no case can the value b be modified without being followed immediately with a variation in the speed of rotation of the magnets so as to bring it back to a point at which it again equals the value a—that is, to maintain the speed constantly proportional to the current to be measured. We can therefore conclude that this meter carries out thoroughly the conditions demanded—viz.:

$$W = \int^t E\,I\,d\,T;$$

in other words, that it is really what it pretends to be, a meter of electrical energy.

From the foregoing it is seen that any variation of friction in the parts of the Brillié meter will have no influence on the meter registration, but solely upon the value $e\,i$ of the small current required to drive the motor.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE I.—INTRODUCTORY.

In 1885 I had the honour to deliver a course of lectures here on the "Distribution of Electricity." This followed a long paper I had read to the Society of Telegraph Engineers on the "Heating of Conductors," when I got out tables for practical electricians of the sizes of wires to be used with different electric currents to prevent over heating. Up to that date the distribution of electricity had been but little studied, and numerous serious mistakes were being made. My object at that time was to lay down in clear language the scientific conditions which must underlie any scheme of distribution. At that time, the more modern plan of using high tension alternating currents was hardly developed, and the advocates of high tension were engaged on storage batteries, and on various parallel series systems, which introduced the high tension actually into houses.

When I arrived at the conclusion that, for a central station supplying 100,000 lamps, the copper conductors leaving the central station must, on the most economical principles, be equal to two cylinders of copper, each equalling the thickness of a man's body, it seemed that low tension was doomed.

No single invention of any importance has added to our facilities in low-tension distribution, so as to affect the dimensions of the conductors, and yet low-tension distribution has done much solid work on a large scale. When asked by the council of the society to give a course of Cantor lectures I felt that at the present date, I could not do better than supplement my previous course, and bring my work on electrical distribution up to date; and it will be well also to examine the reasons why the objections which formerly existed against low tension distribution have so far been overridden that millions of pounds sterling have been invested in it.

* Cantor Lectures delivered before the Society of Arts.

The present course of lectures is intended primarily for electrical engineers, and it is to them that my principal remarks will be addressed, but there are many present who have no intention of putting what they hear to practical use, and it will not be out of place if I indicate briefly some of the points that have to be attended to in electrical distribution.

The resistance offered by conductors to the electric current causes two sources of trouble. One is that energy is absorbed and wasted, and this may seriously affect the coal bill and the total machinery required in the central station. The solution of this difficulty is naturally to reduce the waste by reducing the resistance of the conductors. This means that we are to use larger copper conductors. But this increases the cost, and it is clear that there is a definite most economical size, such that, if the conductors are increased in size, the increased interest on capital expenditure swells the cost; and if we diminish the size, the extra machinery required increases it, and the coal bill rises. It is an important function of the electrical engineer to determine in every case this most economical size of conductor. Large experience has generally led to finding the most economical size to be such that the current density shall be not more than 500 amperes per square inch. The other trouble is that when many lamps are in use, and a large current is flowing, the electric pressure is reduced and the lamps are dim. The further distant a lamp is from the central station the lower is its pressure, and the difference in brightness of lamps is particularly observable in the distant lamps. Those near the station suffer no loss. To increase the brightness of distant lamps during the busy hours, the pressure at the station may be slightly raised. Thus we generally find in central station distribution that in the busy hours lamps near the station are brighter than usual, and the distant ones are more dim. This is well shown by diagrams of pressure taken on different parts of distribution mains by self-recording apparatus. This solution of the trouble does not go far, however, as we cannot allow a large variation of pressure in any lamp. The Board of Trade at present allow the large fluctuation of 8 per cent., and it is to be regretted that the supply companies generally avail themselves to the full of this latitude. This is shown by recording voltmeters.

For further improvement in the supply it is necessary to introduce feeders, which are conducting wires going from the central station direct to certain points on the network of distributing mains, where the variation in volts is found to be large. No lamps being connected on to the length of these feeders, the full pressure can be supplied at the point of distribution without other lamps being raised in pressure.

I do not intend to pass further in review the general principles of low tension distribution. The problem and the rules to be followed were completely worked out in detail in my previous Cantor Lectures; and after these last seven years of busy work, I have not one word to alter in all that I said at that date.

Nor have I the intention in the present course to do what might be an interesting proceeding—viz., to describe the various central stations which have been erected in these years, and analyse and criticise their modes of working. Some of the stations with which I have myself been connected as consulting engineer have been low tension and some high tension, and it might have been thought desirable that I should give you the results of my own experience. Moreover, as is well known, I have largely devoted myself to a careful study on the spot of a large proportion of the central stations both in Europe and America, and I might easily have found materials in this experience to occupy a few evenings with profit. I have, however, other aims in these lectures, and descriptions of central stations are not wanting to those who are sufficiently interested in them. I have myself given full details of the

machinery and methods employed at some of the great European stations in a paper read before the Institution of Electrical Engineers in 1889. A very interesting account of central stations in Germany, by all the best manufacturers, was brought out in a handbook published last year at Frankfort for the Exhibition.* My desire is to carry into these lectures the same spirit that led to my previous Cantor Lectures, and to bring before engineers the points that require attention to make our work as perfect as possible, and to draw attention to the lines in which we may hope to overcome the great drawbacks which still hamper the industry, and prevent it from furnishing such economical results as the general conditions of the problems warrant us in expecting. It will, I hope, be found that there are engineering resources at our call which have yet to be invoked before we have reached the final solution of the problems.

As an example, I will point out to you one or two facts in the economy of the subject. One is that central station distribution, as distinguished from isolated plants, involves a huge additional expense in distributing mains. The cost of these must, from the nature of the case, be out of proportion to their earnings until the consumers are much more closely packed than at present.

Another fact is that our machinery is lying idle three-quarters of the year, and earning no dividend. A third is that, owing to the limited period during each day that the maximum demand exists, we waste fuel in heating up most of our boilers for only a couple of hours' work in the evening. A fourth point is, that owing to the irregularity of the demand, we waste a great deal of steam by working our engines much under their full and economical load.

All these points will be fully elaborated in the lectures. The net result is that electricity in London costs twice as much as gas; that it costs more to obtain it from a public supply than when manufactured (for a large establishment) on the premises; that the method of debiting consumers is unfair on those who have the longest hours of working. You must not be deceived by the optimistic calculations of enthusiasts and interested parties. The electrical industry has nothing to fear from competition, and the surest way of gaining the confidence of the public, and of making sound progress, is to openly accept the true state of the case, and acknowledge the difficulties that hamper you, and then apply all the skill at your disposal to overcome these difficulties. In illustration of the points I have raised, I will here only state one or two points.

1. The streets in London are not lighted generally as they ought to be by arc lights. We know, from a most extensive experience, that anyone can set up a circuit of 10 ampere arc lamps with underground mains, and run them with good profit at a rate of £30 per annum, during all the hours that gas lamps are now used—4,000 hours per annum. The cost of the mere current for these from a supply company, at 7d. per unit, amounts to £58. 6s. 8d., double what it would be if privately worked.

2. A careful comparison of the cost of lighting the Athenæum Club with its own machinery, which has been done for many years, with the charges from a supply company at 7d. per unit., shows that the present cost is £894 per annum, including depreciation on machinery costing £1,608, as against £1,452, which the company would charge us.

We must fairly recognise the fact that electricity is twice as dear as gas, and also that where we replace gas by electricity we must increase our expense in warming a house. When this has been granted, we must remember that we save much in decorating and in preserving our books, that we abolish vitiated and dirty air, and that we can keep our rooms cool. These are sufficient recommendations for those who value cleanliness and health, and will spur the ingenious among us to remove the confessed drawbacks.

In order to perfect our systems of distribution in practice, we must keep before our minds the ideally perfect, and depart from that course only at the gain of decidedly practical advantages, and we shall often find that if due caution is exercised we can gain much by very slight departures from the ideally perfect. This is the spirit which has actuated the evolutionists of the modern dynamo, and which enables us to be proud of our 96 per cent. efficiency, while the steam engine, with a hundred years of brain work and millions of money spent on its development, has reached only 80 per cent. efficiency in its mechanical working. Had it not been for the scientific men who took up dynamo construction at the beginning, we would have rested content with the 50 per cent. efficiency originally offered by Brush and others in machines which were thoroughly well designed mechanically, and did their work thoroughly, if uneconomically. At first, designs of complicated character were introduced, in which the rapidly-revolving parts—those requiring most mechanical strength—contained only the following materials: An iron spindle, a wooden hub, and an armature made of iron wire, wound with copper wire, the parts being joined and separated by millinery and paper and sealing-wax. The object of this construction was to minimise the losses. One weak part after another was discarded, until we now have a fairly strong and mechanical armature.

So in electrical distribution. Ten years ago we searched for the ideally best. In each case we made elaborate calculations of the probable consumption in different parts, and we tried to average the relative size of feeders and distributing mains and their points of connection as accurately as possible. We tried to select those points for attaching feeders that would use the least copper, and we tried to devise means of regulating electric pressure in the feeders, so as to waste no more copper or electric energy than was absolutely necessary.

Ten years of practice in central station working has now stereotyped our practice a good deal; and while we do not always lead a conducting wire by the shortest route from each lamp to the central station, and while we do not always attach a feeder to the nearest part of the district it has to feed in normal conditions, still we always have these leading principles in mind while laying out a plan of electric mains, and we readily adopt the general average results of our experience in past work to simplify our system.

(To be continued.)

TRADE NOTES AND NOVELTIES.

LEAKAGE INDICATOR.

A new leakage indicator, manufactured by Hartmann and Braun, has been introduced by their London agents, Messrs. O. Berend and Co. It has the same outward

Fig.

appearance as their ordinary 9in. voltmeter. The difference of potential remaining constant, the readings can be taken direct in ohms. The readings of an earth leakage indicator for a 2,000 volt circuit range from 2,000,000 ohms to 200,000 ohms, and this range can be diminished to any extent—for instance, from 1,000,000 to 100,000 ohms. The instrument has three terminals, one of these being connected to earth and the other two are joined to the mains. By means of a lever handle either of the mains can be connected to earth through a coil in the

instrument. If there is a leak from either main a current flowing through this coil will deflect the needle, and this indicates the result direct in ohms. If the lever be turned to the positive pole it will measure the leak in the negative main, and *vice versâ*. All the parts of the instrument are extremely well insulated, and the coil itself is soaked in paraffin wax. The instrument has been constructed both for continuous and alternating currents, and should prove a most useful addition to central station instruments.

THE HUMAN BODY AS A CONDUCTOR OF ELECTRICITY.[1]

BY H. NEWMAN LAWRENCE, M.I.E.E.

That the human body is no ordinary conductor has been long acknowledged, but the peculiarity of its conductivity and the conditions under which this conductivity varies, are subjects which have hardly yet been satisfactorily investigated.

In a former communication which I had the honour of putting before the association,* I set forth certain observations on the resistance of the body to different forms of current. Since then other observers have published results of their investigations in the same direction, and a reasonable approach to the solution of the problem of body resistance has been made.

In the present communication I desire to take up that portion of the subject which deals with the conductivity of the body rather than with its initial resistance—to see what is the effect of a passage of current after the first resistance has been overcome and to find what are the differences of conductivity in the several parts.

The value of a true knowledge of the conductivity is of scarcely less importance in connection with accidental contacts with light and power circuits than that of initial resistance itself. It may easily happen that by the continued passage of current for a short time, the conductivity may be so improved that a voltage which at first was practically harmless, becomes ample to pass current enough to be fatal.

The experiments herein described were designed to show, first, the effect upon conductivity of the passage of a steady current for a few minutes, and second, to indicate the relative conductivity of different parts of the body after such currents had passed. Before going further, it may be well to glance at the position of affairs regarding the resistance of the body as a whole. Numerous investigators have given the matter their attention, notably Erb,† Lant Carpenter,‡ and Stone,§ and a gradual evolution of the truth has resulted, till to-day we find ourselves, not, indeed, at the complete solution of the problem, but in a fair way to arrive at it. We find that the resistance of the living body is by no means a fixed quantity, at any rate when the skin is included in the circuit. That it may vary from half a million ohms, with small contacts and dry skin, to 540 ohms, with very large contacts and soaked skin, as shown by Dr. Hedley in his recently published book.‖ That its value between extremes depends upon the contact area and the degree of moisture, as shown by Dr. Harries¶ and myself. That the situation of the contacts in relation to the number of sweat glands covered has considerable influence, as demonstrated by Erb†. Further, that this resistance is much greater to continuous currents than to alternating currents, as found by Dr. Stone,‡ who gives the proportion as 2 to 1, and by Dr. Harries and myself,¶ who give the minimum proportion as 1·5 to 1.

Some investigators have concluded or assumed that the whole of the body resistance resides practically in the skin. Erb seems to be of this opinion, for in his work already referred to he speaks throughout of the "resistance of the skin." Jolly says, "the resistance of two layers of cuticle is equivalent to about 300 times that of the remaining tissues when a current is transmitted from one hand to the other."* The extent to which this may be true is yet unproved, I think, though there can be little doubt that a large portion of the whole resistance does reside in the skin when unmoistened.

Various attempts have been made to eliminate the skin resistance altogether, and so arrive at that of the tissues only. Carpenter, by means of soakage in salt and water for 60 minutes, arrived at a point beyond which the total resistance would not be reduced. Stone, by similar methods, claimed to have found the true body resistance; but in both cases the conclusion seems to have been more assumed than proved.

Waller, in his recent valuable work on physiology,† gives the resistance of the skin as from 1,000 to 100,000 ohms, according to moisture, but does not accompany the statement with any particulars of how the figures were arrived at. Does he mean one or two layers of cuticle? Was the skin cut out, or in any way separated from the body? What was the contact area? Did he intend his figures to refer to the whole body resistance, on the ground that the portion due to substances other than the skin is so small as to be negligible? The absence of these and similar particulars is much to be regretted, and without them one hesitates to use the figures as a basis for other calculations, even though coming from so eminent an authority on matters physiological. My own observation goes to show that not only the skin resistance, but that of "two layers of cuticle, plus the remaining tissues included," may be brought below 1,000 ohms, sometimes with continuous current, and frequently with alternating current. As readily stated, Dr. Hedley has found the resistance of the whole body, including the skin, may be reduced to 540 ohms; while in a recent electrocution (MacElvain), the body resistance to alternating currents proved to be as low as 516 ohms from hand to hand, and 214 ohms from head to calf.‡

The conditions under which Dr. Hedley arrives at 540 ohms as the resistance of the whole body, justifies us in regarding that as the minimum under most favourable circumstances—*i.e.*, in a bath when low E.M.F. is used; but we are still left in the dark as to how much, if any, of the resistance so obtained belonged to the skin only.

I have sought to get over this difficulty in a different manner. By inserting two internal electrodes of fairly large area, one in the mouth and the other in the lower part of the body, after passing the current for one minute, I found the resistance to be 534 ohms. Then while the lower electrode remained *in situ*, one of the non-polarisable electrodes described below was substituted for the mouth electrode, and placed upon the cheek outside the mouth. After again passing a current for one minute, the resistance was 1,468 ohms. The difference between these two resistances—viz., 934 ohms—may, I think, be fairly taken to represent the resistance of the skin under one electrode, and, this doubled, gives 1,868 ohms as the resistance of two layers of skin as in ordinary contacts. This conclusion, however, is only good for skin on the cheek or similar skin, with a circular contact of 2in. diameter to each electrode. Skin in other parts of the body may have a greater number of sweat or other glands in such contact area, or it may have fewer, and this, as shown by Erb*, causes proportional variations in resistance independent of other conditions.

The observations recorded below were all taken upon one subject. Two other subjects were tested, and the readings so obtained, while differing somewhat in value, bore out in the main the proportions shown by the first.

Special non-polarisable electrodes were used. They consisted of glass cups, having each a side orifice, 2in. in diameter, covered with a piece of thin bladder. Each cup was filled with a strong solution of zinc sulphate, into which a zinc rod dipped, the other end of the rod passed through a rubber stopper in the neck of cup, and formed

[1] Paper read before the British Association at Edinburgh.

the terminal to which the battery wire was connected. These electrodes were warmed up to 95deg. F., by immersing the glass body of the cup in warm water till ready for use. When warm, the resistance of the two was 14·5 ohms. When in use the bladder-covered orifice was placed upon the skin. An excellent contact, having only a thin membrane between the skin and a strong saline solution was thus obtained, and it was hoped that complications arising from dry skin, imperfect contact, difference of temperature and surface polarisation, were thereby eliminated.

An ordinary Leclanché battery of 14 cells, giving an E.M.F. of 15 volts, a switch, a current reverser, and one of Edelmen's suspension milliampere-meters, completed the apparatus used.

TABLE B.—Direction transverse—other conditions as in Table A.

" " left hand	0·6	0·53	0·54	0·56	0·56	0·53
Right hand and left hand	0·2	0·25	0·25	0·25	0·25	0·25
" foot (sole) and abdomen	0·3	0·6	0·6	0·55	0·5	0·5
Left " " "	0·9	0·75	0·68	0·6	0·56	0·55
[illegible]t foot and left foot.........	0·3	0·33	[illegible]	0·34	0·34	0·32

The first thing one notices in these tables is the difference in conducting power of the several parts of the body, and in order to make this point more clear I give in Table C a list of comparisons based upon the figures found at the end of each five-minute period.

TABLE C.—Comparative conductivity, after passage of current for five minutes at an E.M.F. of 15 volts, taking the conductivity from hand to hand as 1.

Longitudinal currents.	Conductivity.	Transverse currents.	Conductivity.
Hand to hand	1·0	Through foot	1·2
Foot to foot	1·3	" hand	2·3
Right foot to abdomen	2·0	" chest (side to side)	6·4
Left hand to breast	2·1	" abdomen (back and front)	10·8
Left foot to abdomen	2·2	" thigh	13·0
Right hand to breast	3·0	" lower leg	14·0
Arm (whole)	4·9	" chest (back and front)	14·0
Forearm	6·0	" forearm	20·0
Lower leg	6·4	" upper arm	23·2
Leg (whole)	9·6		
Front of body	15·6		
Upper arm	20·0		
Thigh	20·3		
Back of body..	29·6		

These figures indicate that there is less conductivity in all parts of the body to transverse currents than to longitudinal ones, even though the distance between the electrodes is very small in the transverse tests. The conductivity of the trunk lengthways is 29·6, while crossways from side to side it is only 6·4 and back to front (about half the length) its highest value is 14.

A curious feature brought out by these records is, that in no case does the conductivity of a whole limb lengthwise correspond with the sum of that of the two sections of which that length is composed. It is considerably less even when we take into account the additional contacts necessary for the sectional readings. I had hoped to find in the readings some indication of the skin resistance at these points, expecting that the difference between the resistance of the limb as a whole, and when taken in sections would represent the value of the resistance of the additional contacts. For example, the whole arm gives 11,758 ohms, and the sectional readings are 9,758 and 2,588, making a total of 12,346. The difference is, however, only 588 ohms, and in the light of other readings is far too small to fairly represent the additional contacts. We have, then, to conclude that the greater part of the limb resistance lies in the hand contact or the foot contact, as the case may be, and there is indication that this is due not so much to the condition of the skin at these points as to the nearness of bony structure to the surface. This view is somewhat confirmed by the great resistance shown by both the hand and foot when the current was passed through them transversely.

I next tried the effect of reversals as shown by Tables D and E.

TABLE D.—Effects of reversals. Longitudinal currents. The reversals made by hand with an ordinary reversing key at the end of each five minutes passage of current, as in Table A and B.

Position of electrodes.	No. of reversals.	Effect on conductivity.
Arm—Hand and shoulder	4	no change.
Hand and elbow	4	C reduced by 0·2 ma.
Elbow and shoulder	4	no change.
Leg—Foot and hip	4	C increased by 0·1 ma.
Foot and knee	4	C reduced by 0·1 ma.
Knee and hip	2	no change.

TABLE E.—Effect of reversals. Transverse currents. Conditions as in Table D.

Arm—Through hand	4	C reduced 0·1 ma.
,, forearm ...	4	C increased 0·3 ma.
Leg—Through foot	4	No change.
,, calf	4	No change.
,, thigh	4	C increased 0·2 ma.

The small effect of reversals here shown is probably mainly due to the fact that owing to the special electrodes used and the temperature of the strong saline solution within them, the skin at points of contact had become a fair conductor. It has already been shown that when the skin is thoroughly moistened, the difference between the resistance to continuous current and that to alternating current is very much less than when it (the skin) is dry.*† It seems, therefore, fair to conclude that the precautions taken had the effect of reducing the surface polarisation to a minimum.

For the more convenient study of the observations here recorded, I have plotted some curves. Those shown in Diagram I. illustrating what happened when the current passed longitudinally, and those in Diagram II. what happened when it passed transversely.

These results of experiment are put forward as indicative rather than conclusive, because though they are true as far as they go, and under the conditions named, yet individual conductivity varies considerably, and other conditions of test may give other results. It is more than probable that the conductivity of the body is greater as a whole when subjected to the comparatively high E.M.F. of light and power circuits, but it is hardly likely that the distribution is altered. Many more subjects must be tested in a variety of ways before definite laws can be established, but it is to be hoped that the day is not far distant when this shall be accomplished, and I for one will continue my efforts in that direction.

It is necessary to emphasise the fact, especially in the light of resistances to alternating currents found in the electrocuted criminals in America, that the effects of alternating currents on the body are not touched upon in this present paper.

* *Journal* of Institute of Electrical Engineers, No. 86, vol. xix.
† Paper by Mr. Swinburne, British Association, Leeds, 1890.

WHITEHAVEN.

In order to test the feeling of the inhabitants with regard to the taking of the electric light, the following circular has been issued:

"Whitehaven Town and Harbour Trust,
"Town Hall, Whitehaven, August 20th, 1892.

"As you are no doubt aware the Trustees are about to erect plant for the generation of electricity for lighting the public lamps of the town, and also for the use of private consumers. It is proposed in the first instance, for purposes of private supply, to lay electric mains in a limited area only, viz., King street, Tangier street, Lowther street and Corkickle; but provision will be made whereby the area of supply can be easily enlarged as demand arises. Before doing so the Trustees are anxious to carefully ascertain what demand for the supply of electricity can be depended upon in the above area, and as your premises are within it, will you please inform the trustees, on the enclosed form, whether you propose making use of the light upon your premises, if so, and to what extent. The cost of the supply will, of course, vary with the demand, the greater the demand the less will be the price at which the trustees will be able to supply the light. The prices proposed to be charged at first are: For each Board of Trade unit of electricity per hour in the maximum power demanded by any consumer a charge of 30s. a quarter; and in addition for each such unit supplied a charge of 2d. per unit. A Board of Trade unit of electricity is equivalent in light to about 32 ordinary gas burners consuming four cubic feet of gas per hour each. The cost of lighting under the above charges will greatly depend upon the number of hours during which the light is used by consumers, and in comparison with the cost of lighting by means of gas (light for light) as follows:

"When the light is used for an average of

1 hour per night it is equivalent to gas at				4s. 0d.	per 1,000ft.
1½	,,	,,	,,	3s. 1½d.	,,
2	,,	,,	,,	2s. 8d.	,,
3	,,	,,	,,	2s. 2½d.	,,
4	,,	,,	,,	2s. 0d.	,,
5	,,	,,	,,	1s. 10½d.	,,
6	,,	,,	,,	1s. 9½d.	,,

"In addition to the cost of the light will be the meter rent at 10 per cent. on the cost of the meter, as with gas meters. Besides the moderate price, as compared with that paid for gas, are to be considered the undoubted advantages of cleanliness, brilliancy, and clearness of the light, absence of heating, and purity of the atmosphere of the rooms where used, and a perfect freedom from danger of explosions. The consumer will, of course, provide his own internal fittings and lamps, either by purchase or hire; and as regards these he is advised to make his own inquiries, the cost of same varying very much in the character of the fittings, the position and number of lights, and the internal arrangement of the premises to be lighted but may be taken to cost the purchaser on average from 15s. to 20s. per light installed. It is particularly requested that replies on the accompanying form be filled in as early as possible, as the forms will be collected on or about Saturday, the 27th inst.—Yours obediently,

"JOHN COLLINS, secretary."

NEW COMPANIES REGISTERED.

Kennedy Storage Battery Company, Limited.—Registered by C. H. Hodges, 12, New court, Carey street, W.C., with a capital of £100,000 in £1 shares. Object: to adopt and carry into effect an agreement, expressed to be made between Patrick Kennedy and C. J. Diss of the one part and this Company of the other part, for the acquisition of certain letters patent relating to improvements in secondary or storage batteries, and to carry on in all its branches the business of electricians, electrical engineers, electrical contractors, mechanical engineers, suppliers of electricity, and manufacturers of electrical appliances of every description. There shall not be less than five nor more than 10 Directors, the first to be elected by the signatories to the memorandum of association. Qualification, 500 shares. Remuneration to be fixed by the Company in general meeting.

BUSINESS NOTES.

Western and Brazilian Telegraph Company. —The receipts for the past week after deducting 17 per cent. payable to the London Platino Brazilian Company, were £3,283.

West Hartlepool. —Messrs. R. H. Barnett and Co., electrical engineers, of Volt Works, Walker Gate, Newcastle-on-Tyne, have obtained the electric light contract for the West Hartlepool Co-operative Society's new premises.

Hammond and Co. —Besides the Dublin station just finished, this firm has in hand central stations for Leeds and Blackpool, while preliminary preparations are going on for erecting the electric light works for the Burton-on-Trent Corporation.

City and South London Railway Company. —The receipts for the week ending August 28 were £805, against £717 for the same period of last year, or an increase of £88. The total receipts for 1892 show an increase of £558 over those for the corresponding period of 1891.

New Telegraph Station. —A new station for the reception and delivery of transatlantic telegrams will be opened by the Direct United States Cable Company, Limited, to-day, at 39, Mark-lane, E.C., which will be in direct communication with the Company's transatlantic cable system.

Mansion Lighting. —Messrs. Ernest Scott and Mountain are busy with installations for private houses, having in hand a large installation for Lord Ellesmere at his house and training stables at Newmarket, and are also lighting Benmore House, the residence of H. J. Younger, Esq., Argyleshire. Amongst local contracts may also be mentioned the lighting of Manor House, Newcastle-on-Tyne, the residence of James Knott, Esq.

Coventry. —Owing to the rapid increase in the business of the Coventry Electrical Engineering Company, they have been compelled to remove into larger and more central premises, situated in Ryley-street, Coventry. They have also taken into partnership Mr. W. J. Butlin, who has had a large experience of American electrical work. The "Coventry" dynamo is a solidly-built machine, and is largely in use in Coventry, Birmingham and the neighbourhood. A speciality is made of dynamos for refining, giving 30 up to 3,000 amperes, and dynamos are built to any specification.

Vulcanite. —This material has become one of the most useful and important to electrical engineers, and a rather novel method of emphasising this fact has been taken by the Harburg India-rubber Company, in the shape of the issue of a vulcanite prize medal, one of which the London agent, Mr. F. Winter, of 138, London-wall, has sent us. One of these vulcanite prize medals, which is artistically executed, has been sent out to each of the firms or persons who have received a medal in the recent Crystal Palace Exhibition. They constitute rather a unique advertisement of a firm, a large number of whose hands (in all about 800 engaged in the manufacture of this one material) are regularly employed in the production of vulcanite articles for electrical engineers, counting amongst their regular clients the leading firms in all the different branches of electrical industry—telegraphs, telephones, electric light engineers, accumulator manufacturers, and so forth, as well as the British, German, and other governments. The medal is an interesting souvenir of the exhibition, and an example of the enterprise of the Harburg Company.

PROVISIONAL PATENTS, 1892.

AUGUST 22.

15113. **Manufacture of caustic, soda and potash, and hydro-chloric acid by electrolytic treatment of chloride of sodium and chloride of potassium, and apparatus for this purpose.** Jean Paul Roubertie, Victor Lapeyre, and Ulysse Grenier, 28, Southampton-buildings, Chancery-lane, London.

15120. **Improvements in or applicable to electrical accumulators or secondary or storage batteries.** Henry William Headland, 226, High Holborn, London.

AUGUST 23.

15167. **Electrically illuminated signs or devices, partly applicable to other purposes.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (Almon Dobbins Page and Edwin Joseph McAllister, United States.) (Complete specification.)

15170. **Improvements in or connected with electromagnetic alarm apparatus.** Berthold Hoffmann, 23, Southampton-buildings, Chancery-lane, London.

15179. **Improvements in arm rests for telephone operators.** Joseph R. Bailey, Levi C. Lincoln, and the Woodsocket Edge Tool Company, 77, Chancery-lane, London. (Complete specification.)

15188. **Improvements in electric arc lamps.** Eduard Friedrich Hermann Heinrich Lauckert, 28, Southampton-buildings, Chancery-lane, London.

15194. **A new or improved telephone transmitter.** Erhard Ludwig Mayer and Alexander Chalmers Jameson, Norfolk House, Norfolk-street, Strand, London.

15197. **Improvements in electrolytic apparatus.** Hippolyte Marie Emil Andreoli, 61, Chancery-lane, London.

AUGUST 24.

15225. **A new electric contact lamp.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop-road, Balham, London. (Complete specification.)

15238. **Improvements relating to telephonic switching apparatus.** Alfred Rosling Bennett, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15240. **Improvements in jointing or junction boxes for electric cables or wires.** Hayward Tyler and Co., and Charles Pollard Hammond, 77, Chancery-lane, London.

AUGUST 25.

15296. **Improvements in and appertaining to electrical accumulators.** Henry Clay Bull and John Ramage, 15, Water-street, Liverpool.

15298. **Improvements in holders for incandescent electric lamps.** Frank Bryan, 11, Brackley-terrace, Chiswick, London.

15315. **Improvements in electrical batteries and their application for curative and remedial purposes.** Reginald Wilmot Hayes, Newington and Edward Priddle, 1, Queen Victoria-street, London.

15318. **Improvements in electrical transformers.** Henry Harrington Leigh, 22, Southampton-buildings, Chancery-lane, London. (Giulio Maria Apollony, Italy.) (Complete specification.)

15319. **Improvements in and relating to electric batteries.** David Fishman, 45, Southampton-buildings, Chancery-lane, London.

AUGUST 26.

15329. **Improvements in gas, electric light, and lamp fittings.** Edward Horton, 6, Livery-street, Birmingham.

15356. **An improved electro-chemical process for treating iron pyrites, thereby recovering everything valuable contained therein and avoiding all noxious fumes.** Henry Clay Bull, 15, Water-street, Liverpool.

15372. **Improvements in the method and means of obtaining electricity.** William Boggett, 34, Southampton-buildings, Chancery-lane, London.

15377. **Improvements in switches for electric lighting.** Robert Lund Hattersley, 45, Southampton-buildings, Chancery-lane, London.

AUGUST 27.

15405. **Improvements in and connected with telephone switches.** Hermann Oppenheimer, 34, Aldermanbury, London.

15426. **Manufacture of an elastic compound for electrical insulation and other purposes.** John Welch Savage, 28, Southampton-buildings, Chancery-lane, London.

15437. **An improved method of making electrical contacts between parts of electrical apparatus.** William Ernest Gray and William Arthur Price, 6, Bream's-buildings, Chancery-lane, London.

15441. **Improvements in electric arc lamps.** Arthur James Howes, 28, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1891.

13492. **Electrical propulsion of vehicles.** Elmore.

14834. **Electrically-propelled vehicles.** Heys. (Brown.)

15834. **Carriers for electric lamp shades.** Drake and Gorham.

18887. **Electric railways.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

18890. **Rotary-phase current motors, etc.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

1892.

12306. **Secondary batteries.** Lee.

12417. **Electric brazing and soldering.** Mitchell.

12436. **Electric insulators.** Lake. (McCarthy.)

12442. **Electrically lighting and heating railway, etc., vehicles.** Aldet and others.

NOTES.

Maidstone. — The Electric Light Committee has adjourned for a month.

Telephony in Japan.—The number of subscribers in Tokio is said to be over a thousand.

Buckhaven.—The electric light was used last week for the first time at Mulredge Colliery.

Electric Harmonium.—An electric harmonium has recently been constructed in Italy by M. G. Tamburini.

The New Telephone —We understand that tubes have been laid sufficient for the requirements of 15,000 subscribers.

A New Microphone.—It is stated that M. F. Heller, of Nurnberg, has constructed a new microphone, the contacts of which float in quicksilver and touch the membrane.

Electric Welding.—According to Kirkcaldy's tests of welds by Benardos, the mean of the electrically-heated welds is over 18 per cent. better in figure of merit than the mean of the hand-made welds.

Change of Name. — Mr. Reginald John Jones, M.I.E.E. and A.M.I.C.E., has, by a deed poll duly enrolled, renounced the surname of Jones, and will in future always assume and use the surname of Wallis-Jones.

Revoked.—At the last meeting of the Bishops Stortford Local Board, formal notice was received from the Board of Trade that the powers given to the Bishops Stortford Electric Light and Steam Laundry Company had been revoked.

Personal. — Mr. Herbert Laws Webb has returned from his long sojourn in the States for a short holiday in England. Mr. Webb is at the present time contributing some submarine cable reminiscences to our American contemporary *Electricity*.

A New Train Signal.—At a recent meeting of the Société Internationale des Electriciens, M. H. Pellat gave a description of an apparatus intended to indicate the speed of trains, and of a system of signalling proposed to prevent collisions on railways.

Marseilles.—The electric tramway recently established here is running with great success. The line is about six kilometres in length, and the rails are double for a large part of the way. The station contains three dynamos to provide the current for the motors.

Valence.—The central station will soon be completed, in which Heilmann's dynamos are driven by gas engines. The machinery has been constructed by Messrs. Weyer and Richemond, who are interested both in the construction of gas engines and of the Heilmann dynamos.

A Chance for the Gas Journals.—On Saturday evening, August 27, the electric light in a number of the shops in the High-street, Chelmsford, went out for some time. This was caused by the rain-water getting into the pits in which the wires are placed. Of course, nothing ever happens to gas.

Accrington. — The Accrington Town Council on Monday resolved to purchase the gas and water works for £713,220, being 33 years' purchase, subject to the experts' reports being satisfactory, and to the ratepayers' approval. Several councillors urged that the price was too much in view of the progress of electric lighting.

Tenders Wanted.—The Stadtmagistrat of Fiume, Austria, invites tenders for the construction and working of a tramway for both passenger and goods traffic in that town. Electricity may be used as the motive power. Copies of the specification and conditions can be obtained on application to the Stadtbauamt (municipal town building office), Fiume. Offers will be received up to the 1st October, when the tenders will be opened.

Southport.—A somewhat out-of-the-way fine has been imposed upon the Southport Corporation by the local magistrates. It seems that an uncertificated electric launch has been plying between the marine lake and the sea front, and for allowing this the Corporation—as we say—has been fined 20s. and costs. For the defence it was argued that the electric launch was not a ship, and that the Merchant Shipping Act did not apply to craft used on an artificial lake only 4ft. deep. Notice of appeal has been given.

Altrincham District.—A conference of local authorities, including the Altrincham and Bowdon Local Boards, the Altrincham Rural Sanitary Authority, and the Knutsford Highway Board, was held at Altrincham on Tuesday evening to consider a proposition for supplying the electric light to houses, public buildings, and streets in their districts. The members expressed themselves generally in favour of the application of the electric lighting company, and appointed a committee to consider details and report to a future meeting.

Peckforton Castle.—An electric light installation is being carried out at Peckforton Castle, the seat of Lord Tollemache. An engine-house has been built near the entrance to the grounds, which contains a 40-h.p. Robey engine, of the locomotive type, which serves the double purpose of working a saw-mill and the dynamo. The latter is of the Scott-Sisling type. It charges 56 E.P.S. accumulators. From the engine-house a cable, 900 yards in length, conveys the current to the castle. The wiring is being carried out on the concentric system.

Watering Streets.—Our American cousins are nothing if not ingenious and progressive. The latest introduction is in the utilisation of the electric tram line for the purpose of watering the streets. A watering-car, built something after the fashion of the ordinary tramcar, with a horizontal pipe for the distribution of water, is run along on the ordinary track. The distributing-pipe is jointed close to the car, and can be very easily lifted against the side of the car to allow of the passage of ordinary vehicles. It is easily seen, however, that in a great many instances a large track could be watered without having to raise the pipe.

A Correction.—In our last issue, on page 229, when writing on incandescent lamps and current, the word written in the sixth line from the bottom of the second column was *fewest*, which by some mischance got printed *final*. Anyone, however, would see that the latter was an error, it being the lamps which usually require the fewest watts that soon deteriorate, or, in other words, that soon increase their required consumption. We have made enquiries in other directions upon the subject of the note, and we find that the recommendations of Messrs. Siemens and Halske are considered generally to be very good.

Fire on a Mail Steamer.—According to Reuter, the Japanese papers received at Victoria, B.C., discuss the fire which recently broke out on board the mail steamer "Empress of Japan," while in the Pacific, and necessitated the vessel's return to Hakodadi. They condemn the fitting up of electric wires in the inaccessible afterhold, which in time of peace is filled with cargo, and in time of war would contain gunpowder. In the latter case nothing, they declare, could save the steamer from being blown up. It will be seen that this discussion does not attribute the fire to the electric wires, but it points out what may be a grave

defect. We quite agree with the view that the wires should not be inacessible.

Electricity in Mining.—Mr. Irving Hale discusses in the September number of the *Engineering Magazine* of New York the question of electric power in mining. This is done in an article which deserves very careful consideration, because although in this country itself, with certain exceptions, water power is not largely available, in many of our colonies—that is, in the places where our productions should be able on many grounds to compete satisfactorily with the productions of any other country—water power is largely available, and under conditions where it might be utilised for the production of an electric current. The industry in England, then, should see that the agents abroad are kept fully alive to the importance of not neglecting this development.

Falmouth.—During a lecture on the "Applications of Electricity," by Mr. R. N. Worth, F.G.S., at which Canon Rogers presided, the lecturer said, unfortunately in the West the large towns were lacking in public spirit, and St. Austell and Okehampton by installations for electric light and power had put them to shame. In Devon and Cornwall the tidal power and the power of the rivers and streams could easily be utilised to supply electricity. In Germany the power developed on the Rhine 100 miles away was by means of a dynamo and copper wire conveyed to Frankfort. In the future he believed electricity would be applied for many domestic purposes, such as driving sewing machines, cooking food, and heating irons, and that plumbers would use it for soldering, and miners in their lamps.

Transmission of Power in Switzerland.—The Vevey engineering works are completing plant for the electrical transmission of 300 h.p. by continuous currents for the Monthey sugar factory. The motive power will be obtained from the Viège, a tributary of the Rhône. The fall of water available is about 108ft., and either one or two cubic metres of water will be used per second, two metres giving 600 h.p. The installation will comprise a generator of the Koechlin type, of 300 h.p., coupled direct to the vertical shaft of a turbine running at 240 revolutions. The E.M.F. will be 1,000 volts, and the distance from the generating station to the sugar factory just exceeds one mile. Two motors of 125 h.p. each will be operated at the factory, and the installation is to be in operation on the 15th inst., when the sugar campaign commences.

Utilising Water.—While the question of utilising the various weirs on the Thames for generating electricity for town purposes is under discussion in more places than one, it is interesting and encouraging to hear that Lord Boston, of Hedsor Castle, near Cookham, on whose estate there is a weir, intends turning it to account for the purpose of electrically lighting his mansion and grounds. This, says the *Windsor Guardian*, is praiseworthy enterprise, but it is not quite so surprising when it is realised that Lord Boston has hitherto had his own private gasometer on the estate for lighting and other purposes, although there are large gas works near by at Taplow. A similar circumstance is that Sir Roger Palmer, of Taplow, has arranged for the supply of electric light through wires stretched over the river from the works of Mr. Bowen, at Ray Mead.

Leeds Electric Lighting.—The construction of the Yorkshire House-to-House Electricity Company's works and plant for supplying the electric light in Leeds is proceeding apace, and we understand that in the course of a few days the work of laying the mains in the streets to be first lighted will be commenced and vigorously pushed on. These streets include practically all the centre of the town, and also the route to Headingley. The company, in their circular to intending consumers dated June last, expressed the opinion that their works would be in operation in November, and the progress already made renders it practically certain that this expectation will be fulfilled. The local firms who undertake the business of supplying and installing the necessary fittings for electric lighting are receiving numerous enquiries and orders, and with the near approach of the time named by the company for commencing to supply light, a considerable rush of business is confidently anticipated.

Bowness. — An extraordinary meeting of the Local Board was held the other day in consequence of an application which had been made to the Westmoreland County Council by an electric lighting company regarding the introduction of the electric light, and the company had applied to the Board for sanction to lay cables throughout the Board's district, and there being a meeting of the County Council it was thought advisable that the question should be discussed without delay. Similar questions to this will probably come before many of the local boards and the county councils. In this case the committee of the County Council have been requested to withhold their decision until it be seen what conditions the company were likely to comply with, and what concessions they were willing to give. Of course, the county council, in conjunction with the local boards, are answerable for the due maintenance of the roads and streets.

Book Received.—We have received from Messrs. E. and F. N. Spon a copy of "The Phonograph and How to Construct It: With a Chapter on Sound"; by W. Gillett. The larger portion of this work, says the author, was originally published in the pages of the *English Mechanic*, but it has been very largely re-written, and is undoubtedly the most complete monograph upon the subject. Our ideas upon the subject of the phonograph are fairly well known. We have never admitted that it could come generally into use for business purposes, but that it is extremely useful for certain scientific investigations, and it may be to assist in constructing talking-dolls and such-like pieces of apparatus. We have no doubt but that it may command a large sale. The book enters fully into the description of how to make it, and we have no doubt that if no patents intervene anyone following the description herein given could produce a very good phonograph.

Lighting of Mines.—A correspondent writes to the *Times* to the following effect: "Electric lighting seems to be the only safe method by which fiery mines can be worked, and in 1886 the report of the Royal Commission on Accidents in Mines dealt very fully with the question, and stated that 'It may confidently be expected that efficient lamps, worked by primary batteries, will ere long be available for use in mines at a prime cost not very much greater than that of some of the best forms of safety lamps and that their maintenance in working order will also not entail much greater outlay and trouble.' Since 1886 there have been several portable electric lamps invented, from which colliery proprietors could make selection, and, although the first expense would exceed that of miner's oil lamps, the weekly cost of maintenance would be about the same as at present, with the advantages of absolute safety and so superior a light that output could be doubled. If mineowners are wilfully blind to the safety of their men, Government should insist upon proper means being taken and compel a better system."

Blackpool Electric Tramways.—At a meeting of the Blackpool Town Council, Councillor Heap, on rising to move the confirmation of the minutes of the Finance

Committee, said that some time ago the Corporation decided to take over the plant, etc., of the electric tramway company, the chief reason being that the agreement of the company with the Corporation had not been fulfilled, and especially that they had not provided sufficient accommodation for the public in the shape of waiting-rooms. The Corporation had advertised for tenders for the taking over of the tramways, but none came in, and so they had to take them over themselves. They were placed in a very awkward position. Through the hanging up of their Bill in Parliament, as a result of the dissolution, they had no power to pay the company out. However, these difficulties had been largely overcome and a very satisfactory end come to with the company. They asked for £15,750, this sum to discharge all liabilities. He thought it was very satisfactory that an understanding had been come to without having recourse to arbitration. Towards this sum they had borrowing power for £6,500, and they had decided to borrow £9,500 to complete the purchase. The minutes were confirmed.

Business Methods.—No doubt many of our readers have heard of the method by which some enterprising City men manage to rake in the current coin of the realm when they promote a company, no matter whether the company is good, bad, or indifferent. It is by sending thousands of circular letters broadcast through the country, such circulars being highly laudatory of what is being put on the market. No doubt this is business, and those who become shareholders deserve no sympathy. Something like this goes on in electric lighting. We find syndicates and companies, more or less known or unknown, writing letters to all local authorities, and ofttimes these letters contain statements which are somewhat different to what practice will confirm. We have no objection to urge against this method of obtaining business providing the statements made are correct. At other times the local authority takes the initiative, as does frequently a private individual, and writes to various firms and companies asking for a volume of information about this, that, and the other, with no real intention of, at that time, transacting any business. It is exceedingly difficult for business men to know whether an application for business is *bonâ fide*, and when it is not so the result frequently causes a vast amount of trouble and expense, while there is nothing to be gained thereby.

The Brush Company's Works.—The current number of the *Manufacturers' Engineering and Export Journal* deals this month very exhaustively with the Brush Company's works, both in London and in Loughborough. The article is, we were going to say, exhaustively illustrated—containing, as it does, portraits of the directors and managers, as well as illustrations of the company's works and the apparatus made. We take from the article the following list of the principal central electricity supply stations equipped by the Brush Company: Mordey-Victoria alternate-current transformer system: Avila (Spain, in progress), Bangkok, Bath, Bejar (Spain), Bilbao, Bournemouth, Cape Town (harbour offices, wharves, etc.), Carces (France), Durango (Spain), Embrun (France), Exeter, Hastings, Huddersfield (in progress), Kapurthala (India), La Plata, Lequeitio (Spain), City of London (Central and Western Divisions), Lynton, city of Mexico, Minas (Brazil), Newcastle-upon-Tyne, Segovia (Spain), Shanghai, Sheffield, San Carlos do Pinhal (Brazil), Temesvar (Hungary, streets lighted exclusively by electricity), Worcester (in progress). Direct-current system, with accumulators: Chelsea and Manchester. Direct-current low-tension system, without accumulators: Greenock, Naples, Novara (Italy). Brush series system: Brighton, Eastbourne, Hastings, Hyères (France), Kimberley, Launceston (Tasmania), City of London (temporary installation, 1881-1886), Marseilles, Riverstone (Queensland), St. Saviour's District, Southwark (temporary lighting, 1881-1886).

Melbourne.—In Australia, as in this country, it will be found that some of the earliest clients of electricity, and, in fact, electrical apparatus, are to be found in the banks and large insurance offices: thus the new offices in Collins-street for the Native Mutual Insurance Association are to have one of the most complete electrical installations in Australia. Messrs. Pascoe and Gosche, to whom the contract for the entire electrical installation has been let by Mr. R. Gamlin, are now proceeding with the wiring of the building for the electric light, enquiry indicators, and a complete telephonette service, etc. A special feature in this installation is the fact that nearly all of the fittings are to be manufactured in Melbourne. The telephonettes, which are a colonial invention, and manufactured by Messrs. Pascoe and Gosché, are distributed all over the offices of the building, connecting the latter with a number of similar instruments in the entrance hall, placed there for the convenience of the public. The whole electrical arrangement in the entrance hall is mounted on an artistic framework in Gothic style, and designed by Mr. Beaver, the architect of the building. The work is being carried out under the supervision of Mr. W. A. Gosché. The development of electric lighting in the Australian Colonies must be partly placed to the credit of the agents of the English companies who reside there, who are very energetic, and are well supported in many instances by the people at home. Take, for example, the Brush Company, which for the purpose of giving information has just issued a booklet containing matter compiled, to a great extent, from lectures by Mr. W. H. Preece, F.R.S., and Mr. R. Percy Sellon, M.I.E.E., which is very interesting reading.

Therapeutical Effects of Alternating Currents. Experiments have been undertaken by Dr. J. Larat and M. J. Gauthier to ascertain what the influence of electric treatment by means of alternating currents might have upon nutrition in cases of illness. The same as d'Arsonval utilised in his experiments a method based on the measure of the respiratory capacity to determine the influence of electric currents from a physiological point of view, so MM. Larat and Gauthier estimate the results of electro-therapeutic treatment by a chemical analysis capable of revealing, as it were, this direct influence, or at least its resultant. This analysis is the treatment of the urea, a process which reveals the degree of oxidation of the globules of blood, under an approximate value in regard to the influences caused by the varied range of alimentation. The experiments have shown that alternating currents could increase the respiratory capacity by 50 per cent. The electric treatment, says the *Bulletin Internationale de l'Electricité*, consists in the application of baths in the form known as hydro-electric baths, the current, after passing through transformers and special graduators, being brought to the bath by two carbon electrodes. It has been found by experiments extending over a year that the electric treatment has effected a perceptible improvement in cases of gout, chronic rheumatism, diabetes, obesity, etc., and in all persons having "relaxed nutrition." In several cases the relief found from the first few days has been accompanied by a cure, and, among other things, it was noticed that with certain corpulent individuals a single bath was sufficient to reduce the weight by 250 grammes (8¾oz.), notwithstanding the fact that the appetite of these persons increased. M. Larat also found it possible to cure several

persons suffering from eczema, and from this result he and M. Gauthier think that it will probably become possible to modify the temperament of certain scrofulous children.

An Electric Fire Station.—It is with deep concern that we find our contemporary the *Journal of Gas Lighting* for once—so far as we remember for years past—mentioning anything electrical without sneering at everything connected with it, or putting it down as an absurdity. Messrs. Siemens, however, have, it seems, converted the usual irate medium into something savouring an approach to sanity. Many of our readers will recollect the display that Messrs. Siemens gave of their electric fire engine at the Crystal Palace and at Manchester. It seems to be one of those excessively ingenious ideas which, among other applications of electricity, will, when the current is easily obtained, prove of great advantage. This is what our contemporary says about it: "A somewhat remarkable suggestion for the occasional utilisation of electric lighting currents distributed by street mains from central stations is contained in the so-called electric fire engine manufactured by Messrs. Siemens Bros. and Co., Limited. The carriage and frame of the engine are of the pattern adopted by the Metropolitan Fire Brigade, and made by Merryweathers. The usual steam boiler and pumping engine are, however, replaced by a Siemens electric motor, driving an 'Oddie' pump, which, by the way, looks as if it might be used for exhausting gas. The idea is to fix iron pillars, similar to hydrants, at convenient positions in the streets, carrying two branch wires from the electric mains, which terminate in a concentric union, to which a flexible concentric cable can be attached. Successive lengths of this cable can be connected up if the engine is desired to work at some distance from the junction pillar, and the whole connection is made to look and handle as much as possible like an ordinary hose pipe. Of course, any sort of rotary pump could be driven by the electromotor, but the new 'Oddie' pump has been selected probably because it works at a high velocity, and will stand a good deal of back pressure. The electromotor makes about 450 revolutions a minute, and the pump will deliver at a pressure of 75 tons per square inch."

Telephonic.—Some interesting particulars have been furnished by Dr. Behn-Eschenburg, of the Oerlikon Engineering Works, concerning the influence which the working of the Killwangen Zurich rotary-current installation has had upon telephone wires, and the manner in which the disturbances were removed. It appears that the generating station is situated in the neighbourhood of the Zurich-Baden Railway at Killwangen, about 12½ miles from Zurich. The primary dynamo gives current at a terminal pressure of 50 volts, which is transformed up to 300 volts. The sub-stations are located in Zurich and environs, each having one or more converters which reduce the pressure of the current, which is used both for motive power and for lighting purposes. During the working of the plant, which is reckoned at 300 h.p., regular buzzing noises were remarked in all the telephone wires which were in connection with the sub-stations or the primary station. The telephone subscribers complained of interruptions, which they said were worse in damp than in dry weather. This circumstance led to the supposition that the disturbances were caused by leakage between the strong current and the telephone conductors. At the Killwangen generating station the neutral point of the primary and secondary leads of the transformer were connected to earth, as was also the case in those sub-stations which only supplied current for lighting; whilst in the stations from which motors were operated only the neutral point of the low-tension current was grounded. When the earth connection of the transformer in the station for the distribution of light was interrupted, the humming noises in the telephone of this station almost completely ceased, whilst in the other stations the disturbances continued; but when the earth connections in these stations were removed, the noises in the telephone wires also ceased. A similar result was obtained in all the stations when the earth lead at the primary station alone was disconnected from the earth. The supposition is therefore confirmed by these tests that the interruptions in the telephone wires with this installation were brought about by the passage of current from the earth, which formed the central lead of the system.

Conductivity in Mixed Solvents.—According to the abstracts in the *Journal* of the Chemical Society, Arrhenius has dealt with this subject, which is of considerable interest to those who have anything to do with electrolysis. His conclusions are as follow: "When a portion of the water in the aqueous solution of an electrolyte is replaced by a non-electrolyte, such as alcohol, so that the total volume remains unchanged, the electrolytic conductivity of the solution diminishes. If the quantity of non-electrolyte added (x), does not reach more than 10 per cent. the conductivity of the solution may be expressed by the formula $l = l_0 \left(1 - \frac{a}{2} x\right)^2$, where l_0 is the conductivity of the pure aqueous solution, and a an empirical coefficient. The author has investigated 55 different electrolytic solutions with regard to the influence on their conductivity of six non-electrolytes (methyl alcohol, ethyl alcohol, isopropyl alcohol, ether, acetone, and cane sugar), the strengths of the solutions and the quantities of non-electrolyte added being varied. The decrease of the conductivity brought about by the addition of 1 per cent. by volume of the non-electrolyte (a) depends on the nature both of the electrolyte and of the non-electrolyte, varying between 1·5 and 4 per cent. of the conductivity of the pure aqueous solution. As the concentration of the electrolyte increases, a is in general the greater; and the variability of a with the concentration is such that it is smaller, the greater the degree of dissociation of the electrolyte is. The diminution of the conductivity by the addition of a non-electrolyte is partially due to the increase of the fluid friction of the solution, which lowers the speed of the ions. In the case of substances that are strongly dissociated (most salts, and strong acids and bases), the diminution is due almost entirely to this cause, and the relation between it and the increase of fluid friction may be expressed by the formula $1{,}000\,a = C + 1{,}000\,C'\,(A - 1)$, where A is the fluid friction (compared to that of water as unity) of a solution with 1 per cent. of the water replaced by the non-electrolyte, and C and C′ are constants which are the same for various groups of electrolytes. Here the addition of the non-electrolyte does not alter the degree of dissociation. On the other hand, when the dissolved substances are only feebly dissociated, the addition of the non-electrolyte not only diminishes the speed of the ions, but also diminishes their number. This diminution of the degree of dissociation is greatest with non-electrolytes that contain no hydroxyl groups, becoming less as the number of hydroxyl groups in the molecule increases. Temperature has only a slight influence on the proportional diminution of the conductivity, this diminution, however, becoming always smaller as the temperature rises. The author indicates how to correct the observed conductivity of a solution for fluid friction, so as to reduce the value obtained to that in a liquid whose fluid friction is equal to that of pure water, and, finally, points out the method of applying his results to the determination of the ash in sugar solutions (molasses) by means of observations on the electrolytic conductivity."

SHOULD YOUNG ELECTRICAL ENGINEERS GO INTO BUSINESS?

BY SYDNEY F. WALKER.

In the opinion of the writer of this article, the number of young fellows who have trained as electrical engineers who may hope to be successful in business on their own account is very small indeed. Very few believe this, of course. In some cases it is argued that one's parents, having paid so much as premium, and oneself having worked a certain number of years without remuneration, one ought to be worth a good salary, and if selfish firms will not see matters in the same light, one will have a try on one's own account. In other cases, after perhaps holding fairly good positions for a certain time, young fellows get the impression that they are earning all the profits while their employers are taking them, and doling out to them what they consider a miserable pittance.

In other cases, again, a young fellow has some difficulty in getting a billet that he thinks equal to his qualifications, and forthwith elects to set up on his own account. It must be confessed that youngsters are not the only ones who behave in this way. Often men of mature years do the same. The impression prevails among nearly all engineers that the qualifications necessary to run a business successfully are very much inferior to those required to carry out engineering work; that, in fact, no training, no special abilities at all are needed. Yet the truth is that a very much higher order of ability is necessary to run a business successfully, than for almost any other kind of work, whether it be professional or non-professional. Anyone who will take the trouble to enquire into the matter will find that the success of all large concerns, even large engineering concerns, is due to some able man, not usually an engineer, who is perhaps not seen or heard much of, possibly not much thought of, yet who is to the business what the captain is to the ship, the admiral to the fleet, or the general to the army. Without being as intimate with the details of the different branches of the business as those under him, often knowing very little of those details, as his subordinates understand knowledge of them, he is yet able to guide men who are really his masters in their own departments, and to ensure success where otherwise failure would result. It is usually better, though not always, if the master mind in an engineering business has a good knowledge of the branch of engineering his business deals with, but in very many instances ability in engineering is not accompanied by commercial skill. The man who is an engineer before everything is apt not to count the cost of his work. He has a difficulty to get over, and he proceeds to work his way throught it regardless of everything but the one object he has set before himself.

Or, again, the man who is purely an engineer, without the higher commercial gift, is apt to waste money in producing what may be termed unnecessary and expensive excellence. A dynamo is designed with a certain efficiency. When the work is well in hand, the designer discovers that he could, by certain alterations, have got, say, 5 per cent. higher efficiency. He does not stay to consider whether he will get a return for the additional expenditure. Very often the users of the machine will get absolutely nothing for it. In some cases they will even be involved in larger maintenance charges. Yet the one thing the engineer aims at is to produce a machine more perfect than has been produced before. In a small business, where the engineer is himself also the commercial man, such a course would be fatal to success. In a large concern, where the engineer was only the head of a department, he would not be allowed to involve his firm in useless expenditure of this kind. His chief would soon stop that.

Another reason why few engineers, especially young ones, can be successful in business on their own account is, because of the fact, which is usually entirely overlooked, that they must be their own chiefs of departments as well as their own commercial head. The proprietor of a small engineering business should be a skilled accountant, a clever salesman, a good traveller, a good storekeeper, a good collector of accounts, a skilful manager of men, a good buyer, and should possess other qualifications besides; and his skill as an engineer should be of a very high order, as he must constantly be ready to tackle engineering problems which men who are paid very high salaries by large concerns do not consider beneath them. Where a good working partnership could be formed between an accountant and an engineer, many of the above difficulties should disappear. But this is rarely possible. Accountants usually imagine that they understand engineering better, from the glimpses they get of its outer workings than men who have spent their lives in its study, and though they usually develop into good commercial men from their habit of constantly counting the cost, they do not always. On the other hand, engineers are usually suspicious of accountants, so that the result is, each spends a large portion of the time that should be given to the general good of the business, in meddling with and generally muddling the other's work.

Young fellows who have been on the staff of some large concern imagine that all the duties that have been named—bookkeeping, selling, collecting accounts, travelling, etc.—will be done for them by subordinates just as they were in the business they left. But they forget that if these duties are performed for them, the men who perform those duties must be paid, and if the duties are to be as well performed as in the concern they have left, the pay must be somewhere in the same proportion, and that these payments must come out of the profits of their business. As no small business can possibly afford this, it means that the proprietor himself has to undertake the whole of them, getting just as much assistance in each department as he can afford to pay for. Where there are partners, of course they may lighten the work by dividing it between them, but the result is the same. In those cases where men have succeeded, they have had next to no assistance at all till the increase of business made it absolutely necessary, and the profits allowed it.

Then, assuming that the above is agreed to, that proprietors of small businesses are to be everything, like Pooh-Bah, difficulties crop up right and left when they come to put the principle into practice. Buying men like—it is one of the sweets of business, also one of its greatest dangers. But few men like selling, or canvassing, or collecting accounts, or facing irate contractees, whose non-satisfaction means heavy loss to the contractor. Selling is all very well when the buyer comes with a sweet smile and asks to be allowed as a personal favour to himself to buy, at your price, and to pay immediately. But buyers do not adopt that plan—at least, not when they mean to pay. The seller has to go to them, and to compete with other sellers, and sometimes to put up with very smart rebuffs from buyers who do not wish to be bothered just then.

Again, perhaps there is no more difficult part of a business than getting one's money in. If one happened to be the only seller, and certain people were obliged to buy, the matter would be simple. But sellers are many, and buyers are often not slow to change, if offended by want of tact on the part of the seller. Added to all this, the capital required in every electrical business, except in a few special cases, is very large indeed in proportion to the amount of business that can be done, as compared with other businesses, while incidental expenses are often very heavy. No matter what happens to an apparatus, if injured, the seller or contractor is usually expected to make it good. Even where he is not actually expected to do so, he cannot allow an imperfect apparatus to be in use, with his name attached, as it would lead to serious loss of business. People do not enquire why an apparatus has failed, they see it has failed, and go elsewhere.

Other sources of expense also constantly arise, which make it hard to realise a profit in engineering businesses. The very march of science is against the man who owns a business. Some new discovery is made, some great improvement in construction, and perhaps a large portion of his stock is reduced to the value of old metal. Where a man runs his own business he has to stand all those expenses himself. Where he is merely the engineer to a firm, or to a company, he does not, though he may have been mainly instrumental in causing a large portion of them.

Further, it is worth the consideration of young engineers,

whether it is wisdom to drop out of the race, unless they have reasonable certainty of reaching a good position on the other road. It is, of course, not always possible to keep in one employ, but the most successful men, in the truest sense of the term, are those who do. The man who gets into a sound concern at the beginning of his career, though he may have to accept a small salary, and who remains with the same firm, though he is perhaps not always getting sometimes as large a salary as those who graduated with him, will usually occupy a better, a more comfortable, position when advancing years render it of value to him, than the man who is constantly changing, as he thinks, to better himself. Firms do not always study old employes as they should, but there are few cases where continual service, supported by hard work and average ability, do not bring a substantial reward at the time it is most appreciated.

FIG. 2.

ELECTRICAL TRACTION ON TRAMWAYS.

THE "BRAIN" SYSTEM.

Never before the present time has so large an interest been manifested in the various systems of traction which have of late years engaged the attention of engineers. That a vast open field awaits the introduction of any really good system is best gauged by the eagerness with which those interested in our present tramway companies are investigating modern developments. Horses are expensive and slow, steam is more expensive and dirty, and they are now already convinced that the true course for improvement lies in the adoption of some form of transmission and distribution of mechanical power, as such would not only give a quicker service but increase the public use—a great financial gain—and if less expensive in working be of very great value.

It is generally felt that by the use of electricity the problem will be best solved. The electric accumulator system is very attractive, but wherever it has been used for any length of time it has proved too expensive, and many experienced authorities now strongly doubt if it can be made to pay. The overhead trolley system, which has been so successful in America, has thoroughly established the fact of the "economy" of electrical traction when operated by means of a direct connection to a line conductor. The inconveniences and objections to the exposed overhead wires prohibit its use in most cities, certainly in this country. An underground conduit is therefore the only resource.

Owing to difficulties experienced with those having an open slot, many proposals have been made for using a permanently sealed conduit with a series of short exposed contact rails and different methods for automatically connecting and disconnecting the contact rails and the main conductor, but none of these have been adopted. The great multiplicity of parts, the inaccessibility, and the

impossibility of fixing the various sections and buried parts in a manner capable of resisting the destructive action of the road traffic, appear to prevent them inspiring sufficient confidence.

The troubles experienced with the latter, which led to these proposed schemes, were the failures of the insulation during bad weather and the frequent breakdown of the thin insulating covering on the travelling connection which passed through the narrow slot to the conductor. By increasing the size of the conduit and other proper precautions, the difficulty with the main conductor insulation can to a great extent be overcome. This, of course, entails a proportionate increase in the already large capital cost of a conduit; but the frequent failure of the thin insulating covering, so disastrous to the regularity of the traffic, can only be prevented by the use of a slot wide enough to allow a much thicker covering.

A wide slot, at least 1in. wide, if not more, is therefore *sine quâ non* to maintain an uninterrupted supply of power to the car from the conductor in the conduit. In this country the authorities will not allow it. Moreover, it necessitates a much wider and deeper conduit to accommodate the extra dirt accumulation and prevent the exposure of the conductor, which again greatly adds to the cost. This is the only form in which the open-slotted conduit can be made practicable, but the sinking fund on the heavy capital cost becomes a large item in the total working expenses, and the wide opening in the street is most objectionable. Further, the construction of such conduits requires a great disturbance and deep excavation in the roadway, and even then the general inconveniences of these conduits, such as inaccessibility for repairs and renewals, the effect of ice and sleet in narrowing the slot, and many structural and working difficulties experienced with the conductor and the crossings, are still existing.

To summarise, the successful conduit must be primarily cheap, have a wide slot, and be small, thereby necessitating but little road disturbance. This is the practical issue of the past seven years' experience in street conduits.

The difficulty is to build such a conduit that would be unaffected by bad weather or dirt accumulations, and have a conductor never dangerously exposed. Now the system which is just being made public, known as the Brain "covered conduit," seems to secure these advantages. It is the invention of Mr. C. T. B. Brain, of Bell's-buildings, South John-street, Liverpool, an engineer and electrician of long experience in this work. He was for some time electrician to Messrs. Elwell-Parker, and as engineer has

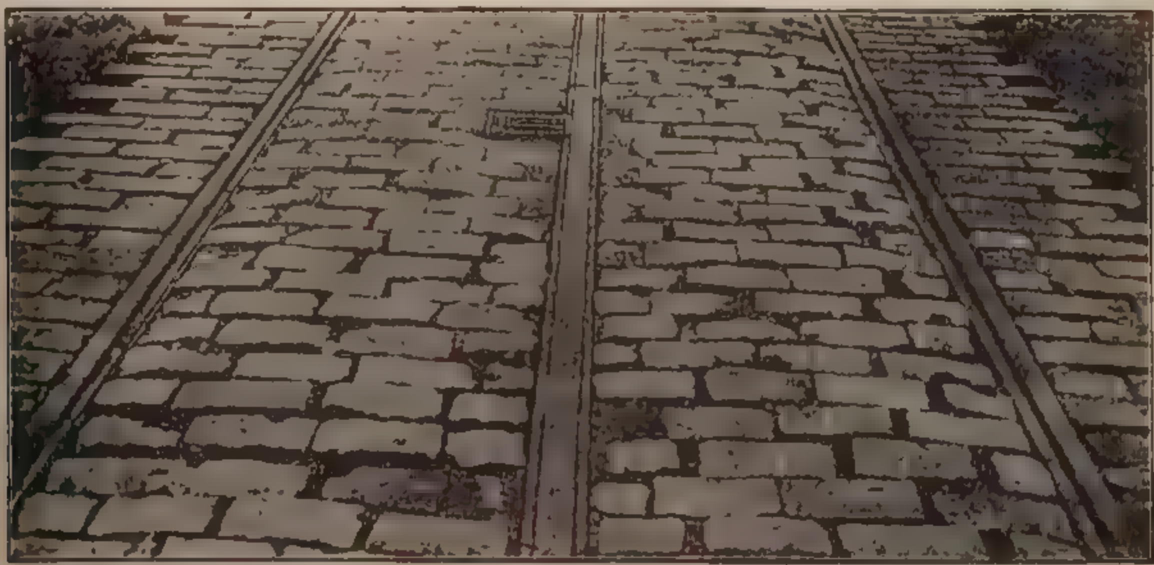

Fig. 3

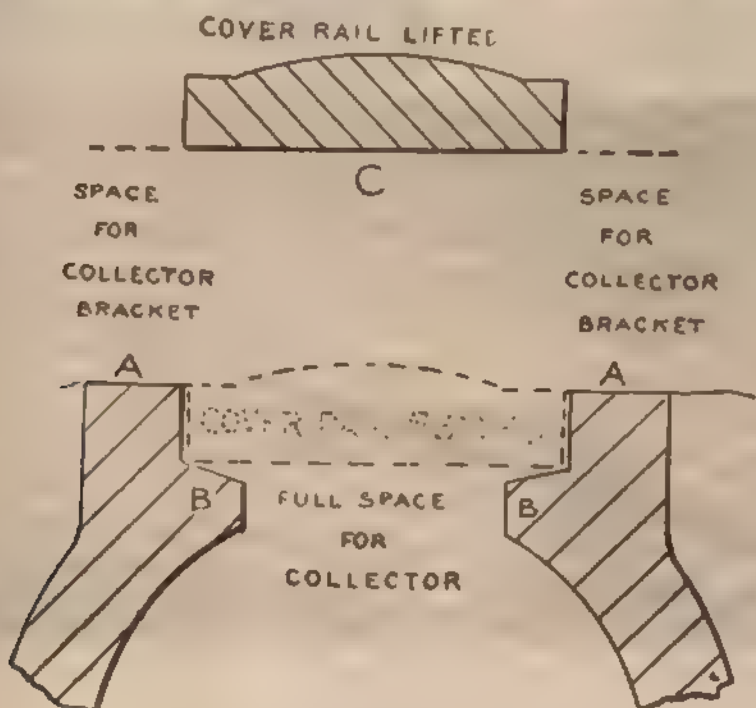

Fig. 4.

had responsible charges at the Portrush and Blackpool electrical tramways, where he successfully carried out various rearrangements. He has proved the system by a series of trials extending over the past two years. His conduit is small and possesses a wide slot; this is covered by a continuous rail, formed of stout flat steel bars joined end to end and called the cover-rail, which sinks flush with the road surface and rests upon a ledge or flange on each side of the slot, thus excluding the dirt and preventing dangerous exposure of the conductor, which is placed centrally underneath the rail.

Fig. 1 well illustrates the general construction. It will be seen that the conduit consists of simple cast iron troughing, laid in lengths, which firmly fit into each other, upon the existing concrete of the roadway, this providing a ready-made and substantial foundation. To obtain access for the connection between the car and the line conductor in the conduit, the cover rail is held up about 1½in. high by rollers underneath it and connected to the car, which we describe hereafter in detail.

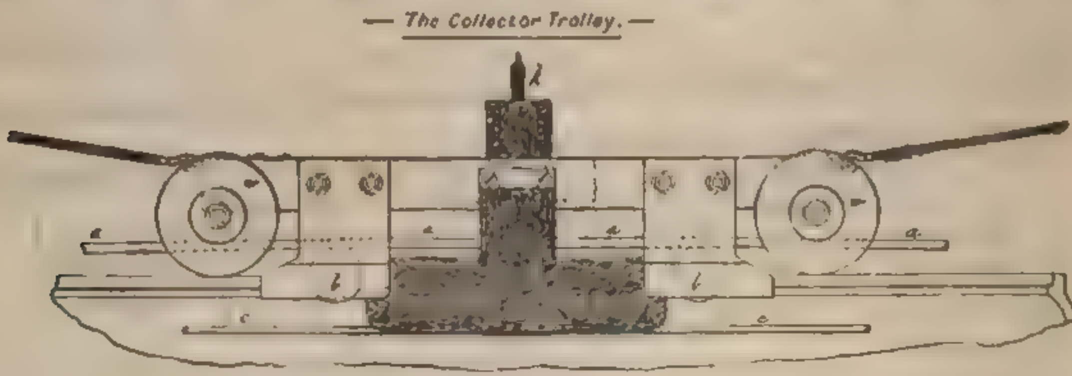

FIG. 5.

FIG. 6.

The most original and practical feature in the operation of this system is the manner in which so strong and heavy a rail returns to its seat on each side of the point of support. Fig. 2 is taken from a photograph of the actual bar used, showing it supported at one point in the middle of the view and the natural deflection which such a bar, lying on a continuous horizontal bed, makes when raised 1½in. high. This is the extent to which it is raised under each car. The cover rail is 2in. wide by $\frac{7}{16}$in. thick, and such a stout bar has but a very gradual deflection, returning to its seat at a distance of 4ft. or 5ft. on each side of the raised position. It is evident that with this section and so short a width the transverse strength of the cover is more than ample. It could bear many tons. Yet it has just sufficient flexibility lengthwise. As it does not weigh 3lb. per foot the maximum load carried due to the working of this rail cannot exceed 3lb. × 10ft. = 30lb. Fig. 3 shows the neat appearance and unobjectionable character of the conduit on the road surface, and also gives a good idea how the conduit is protected from dirt and flooding. Owing to the depth to which the bedded rail sinks into the seat and to its great rigidity in a horizontal plane, always retaining, even when raised, the shape in which it is fitted to the conduit, the action of the rail in returning to its seat is most certain both on straight lines and curves. In practice, as a safeguard this is still further ensured by a roller near each end of the car running on the unlifted rail before and behind the raised portion.

These points will be best understood by reference to Fig. 4, which shows a full-size section of the upper part of the conduit, the supporting ledges, B B, and the cover rail. This last is shown in its raised position, and an idea can be obtained of the space afforded for a large and strong connection to pass into the conduit opening, and of the general strength of all the parts, including the brackets carrying the lifting rollers under the cover rail, as well as of the small vertical depth occupied by the rail, its great transverse strength, and the neatness of the whole arrangement

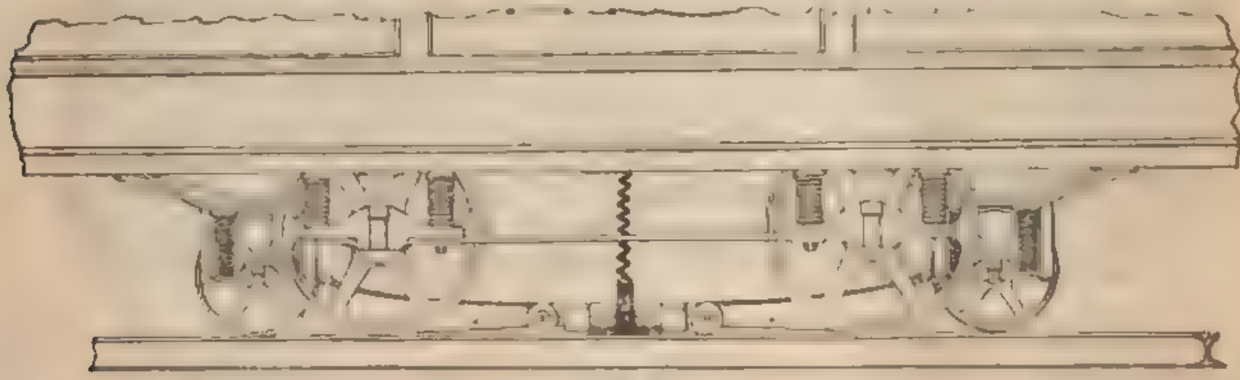

FIG. 7.

This travelling connection with its sliding contact in the conduit is called the collector. It is fixed to the brackets which carry the lifting rollers, there being two of these, one at each end of the collector, and they support the cover rail at C. The whole collector frame is in turn supported by a wheeled trolley, which runs upon the top edges of the conduit sides, A A.

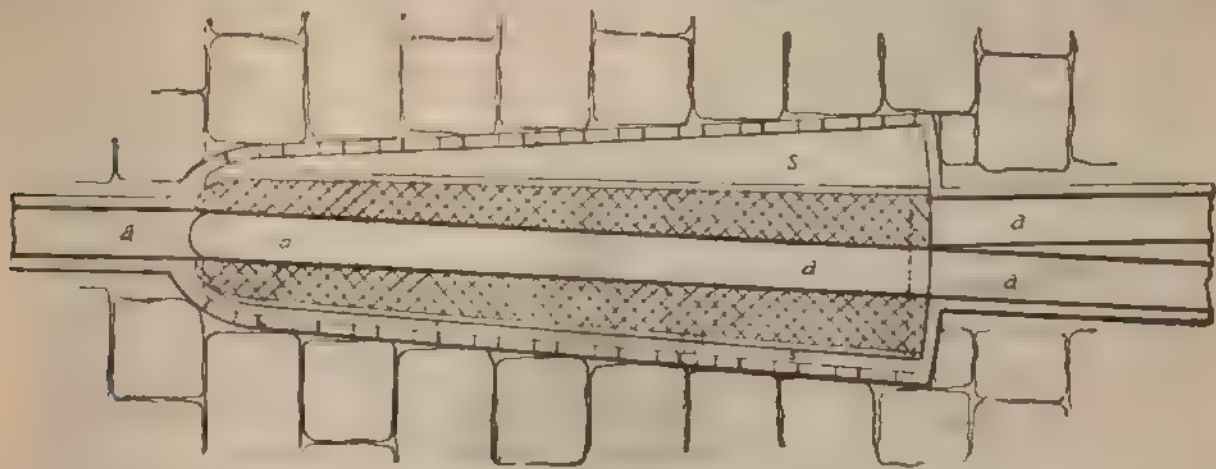

FIG. 8.

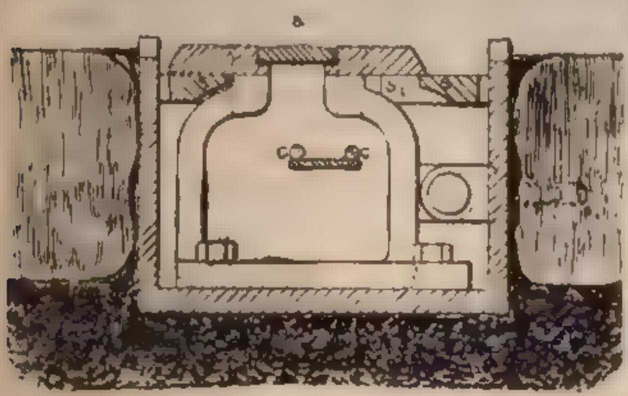

FIG. 9.

Figs. 5 and 6 are an elevation and detailed sections of this collector trolley, in which *a a* is the cover rail, *b* the lifting or carrier wheels, *c* the conductor, and *d* a flat conducting strip, which is the connection passing into the slot, *f* a contact grip, *g* the grip contact piece, *h* the hard insulating block or collector case, *k* flexible cable attached to car, *w* trolley wheels. The trolley is drawn by ropes hooked to each end, and it will be seen that the connecting strip, *d*, is held in a position midway between the surfaces of the cover rail and conduit, and the insulation, already strong, is not subject to the heavy wear and friction. The insulating block, *h*, has let into it a thin steel case like a lock frame, in which work the spring and strong levers attached to the contact-shoe shown in section and dotted in elevation. The grip contact is an insulated connecting plug, used as a convenient form of detachable connection. The car body and wheel base, together with the rollers running over the conduit, and the trolley in working position, are shown in Fig. 7.

The flexure of the cover rail is so very slight that the structure of the metal is in no way strained, its elasticity being so little taxed. The effort due to the operation of the rail is entirely confined to the weight carried and lifted. The weight carried is 30lb., and the rolling friction due to this requires a tractive effort of 1lb. or 2lb. Taking the rise at 2in. instead of 1½in., the weight lifted is 3lb. × 5,280ft. × $\frac{2''}{12}$ = 2,640 foot-pounds per mile, or a pull of ½lb., which with friction should also never exceed 2lb. The total power absorbed is therefore nominal. Even were the cover rail strained there would be no tendency to hog up, as in being lifted and replaced both sides would be in turn stretched. The joints are made to allow a small sliding movement, necessary for working and for expansion and contraction; and small fixed studs prevent the rail moving along the slot.

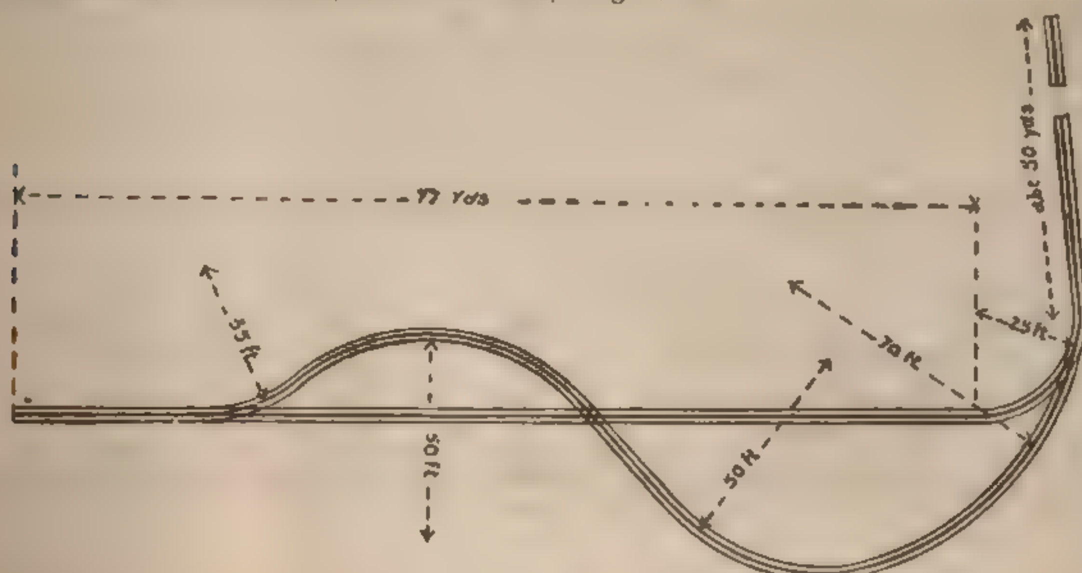

FIG. 10.

A considerable experience has been gained with the working of the rail which has thoroughly confirmed its practicability. Figs. 8 and 9 illustrate the way the cover rail is worked at the points or turnouts; *a a a* show ends of cover rail. At the fork of the conduits, the end

of the rail covering the single line has fastened to it by a stout pivot a short length of cover rail, *a a*, which can move like the points of an ordinary rail. The free end of this is grooved to fit tongues on the ends of the other rails, *a a*, and can be moved into connection with the rail covering the conduit of either route. This is effected by pivoted

Fig. 11

cover-plates on each side of it, which are fastened to a stout U piece passing under the conductor inside the conduit, and shown in the section, Fig. 9. They are made with a ledge on the inside similar to the conduit slot, and in these the rail *a' a* rests. To the U-piece is attached a rod which controls the crossing. Where facing points are used worked by hand, this is connected directly to and therefore must work with them. But in turnouts where the rail points are worked automatically by the car wheel flanges, a simple

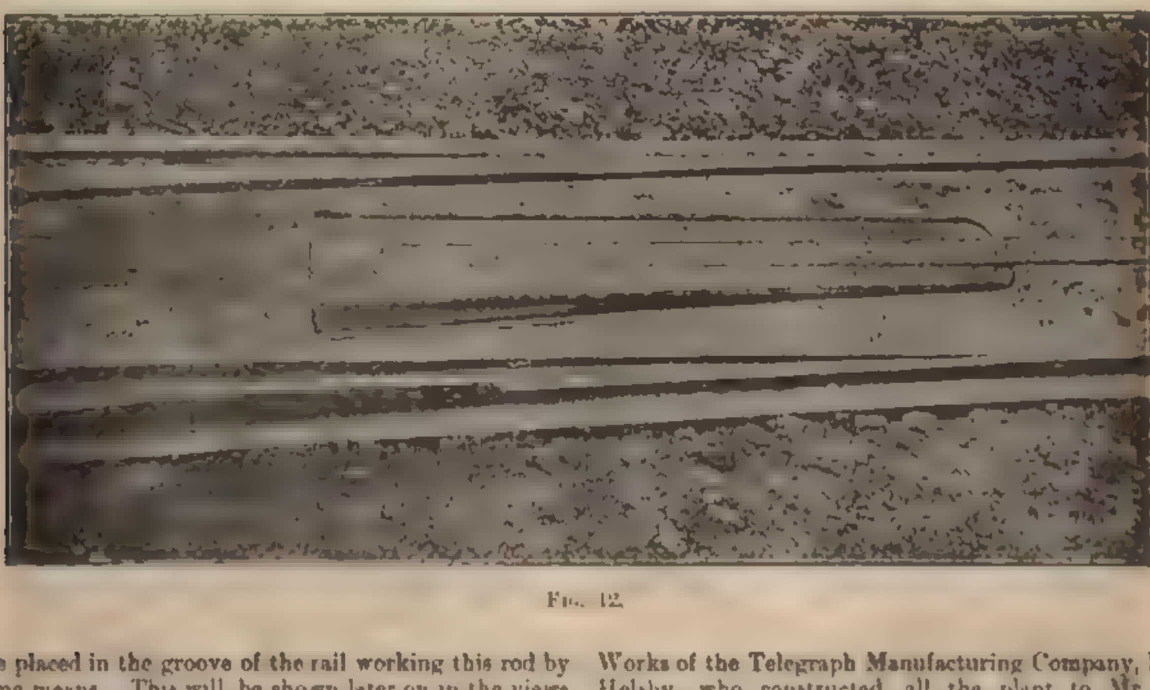

Fig. 12.

lever is placed in the groove of the rail working this rod by the same means. This will be shown later on in the views of the experimental plant.

The pivoted side plates not only cover the large opening and support the rail, but tongue down the end of the rail of whichever conduit is not being used, and make the sides of the slot continuous in the direction they are turned, causing the passage of the collector to be as uninterrupted and certain in action as on a straight line. It is here the advantage is seen of a central conductor with contact made on its upper surface. At the turnouts and all crossings the conductors can be made continuous, as at their junctions they are simply made to present a flattened surface over which the contact shoe can easily slide in either direction

In the account following of the practical work done with this system, a view is given of a crossing, constructed at a most awkward angle, in which the conductors are so fixed, and the cover rail, which in this case has a short bit swung round by a U-piece like a small turntable, is actuated similarly to the above. All the parts have been developed and thoroughly tested during the past two years on a designedly awkward experimental line of narrow-gauge track, but with full size conduit, laid at the Britannia Works of the Telegraph Manufacturing Company, Limited, Helsby, who constructed all the plant to Mr. Brain's designs. Moreover, all the various details and parts of the whole system have been worked out and reduced to standard patterns.

A reference to the plan of the line given in Fig 10 shows immediately the extent of the experimental trials. There is a long, straight piece, on which considerable

speed can be attained, terminating in a sharp curve of 25ft radius, the line then continuing straight at a little less than a right angle for some distance, allowing the curve to be rapidly traversed in either direction. From off the straight length there is a turnout with points made as abrupt as possible; it winds round with curves of 35ft. to 50ft. radii, and passes right across the straight track, cutting it at an angle of 45deg.; continuing, the lines join on the small curve, the two curved conduits meeting form a long, fine point.

Fig. 11 is a general view of this line looking up the straight from near these points, which will be seen at the bottom. Experienced engineers know the structural difficulties of yoking two conduits at such an angle, but with this system there is no long overhanging centre point, as the conduit is narrow and the slot wide. Fig. 12 is the top view of the cover rail and conduit at this junction, while Fig. 13 shows the abrupt turnout, on which the lever in the rail groove can be seen, and Fig. 14 is the centre crossing with the small circular turning piece in the middle, which operates the short connecting-piece of cover rail.

The small cost and mechanical simplicity of the system just meet the requirements of the problem. The economy of working a conduit system has been proved; it is the objectionable slot and inherent faults of the line, injuring the traffic, which have prevented its adoption even more than the great capital outlay required. But this capital involves upkeep, and it is now being realised that such engineering undertakings should have a sinking fund to meet the deterioration of the property. The percentage per annum required on this large capital depends very much upon the frequency with which the line has to be overhauled. This fund, as well as maintenance and repairs, is a part of the true working expenses, and the large proportion it becomes will be seen even in the case of Blackpool, where the conduit was built smaller than now found advisable with the open slot. It cost about £4,500 per mile, and this at only 5 per cent. equals over 1d. per car mile run per mile laid—more than maintenance or fuel, the latter being 0·7d.

The simple construction and working movement of this "Brain" system makes it most accessible for repairs. The cover rail as it sinks in its seat affords no hold on its surface for interference, but throughout its length can be easily and rapidly removed from its seat as fast as the car travels, by loosening a joint, setting the rail on one side, and putting the rear roller of the car out of place so as to

Fig. 13.

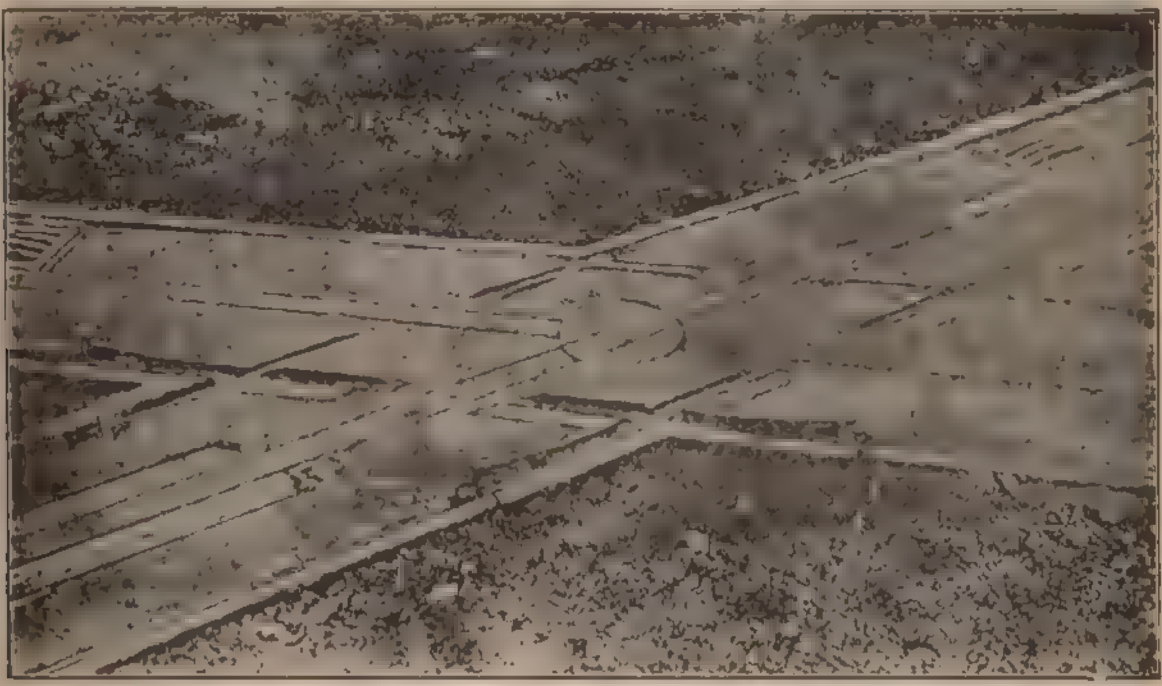

Fig. 14.

lay the cover rail on that side; running the car back replaces the rail.

In every way great economy appears possible with this system, and it warrants an extensive adoption.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 10d.	9s. 11d.	19s. 10d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE LOAD.

Like the weather to the ordinary inhabitant, the load is to the electrical engineer always a topic of interest. There are, however, indications that the special topic will only be of temporary interest, while the weather, like the river, goes on for ever. We say the load is only a matter of temporary interest, and our reasons for this statement will be forthcoming. We know that Mr. Crompton, to mention one example, is among those who contend that our knowledge of central station work has not made those great advances we usually imagine it has. From one point of view he may be right, from another he is probably wrong. Circumstances alter cases, and our words must not be taken as universally applicable. With certain feelings of incertitude we would urge that even now we cannot satisfactorily say what is the best unit of central station, though we may be upon safer ground as to the unit engine and dynamo when we have decided upon a central station. By unit central station we refer to the station or stations to be erected for the lighting of a large town like Liverpool, Manchester, or Birmingham, and with electricity the sole artificial illuminant. At present most central stations run cheek by jowl with gas works. The former method of illumination is a luxury — a luxury undoubtedly permeating downwards, as all luxuries do when they decrease in price and maintain certain agreeable properties. Now, given the problem which must come sooner or later for the total lighting of some such large town, shall we instal our central station of gigantic proportions as large or larger than Deptford, or shall we instal several stations? If the latter, what is the best size of station for economical working and distribution? What in reality is the exact position taken by a central station generating current for a hundred thousand eight-candle-power incandescent lamps? It is wholly insufficient for the needs of a large town, yet there are few central stations that can boast of more lamps wired. According to the drift of present practice it seems preferable to erect several stations, but again comes the question, What is the most economical size? This being determined, we come to the simpler problem of unit combination. This latter is practically determined when lighting alone is under consideration by the load or supply curve, with one proviso that the unit be not so small as to be uneconomical. An engine of two hundred to three hundred horse-power will probably be as economical as one of a thousand horse-power. If an engine of less horse-power than this differs considerably in economy, it is clearly of importance to have a central station so designed that the full load of each successive unit is obtained as quickly as possible and maintained as constant as possible. We have taken the horse-power somewhat at random, inasmuch as the argument holds good whatever the unit adopted—it must be large or small enough to be economical, and to be fully loaded as long as possible during use. The full or light load upon the unit depends upon the size and arrangements of the whole station. With stations fully equipped, and with their full

complement of lamps wired, no unit ought to run long except under full load. This reduces loss. Of course, when we supplement use of current in other directions than lighting, we still further reduce loss, because all the units can be run constantly at full load, and no machinery is idle except that installed as a stand-by, or undergoing repair. Once more, it is not when Manchester, Nottingham, Liverpool, Birmingham, Bristol, Glasgow, and half a score of other large towns determine upon what we now call electric lighting that the question of unit stations will have to be solved, but when the system has percolated among householders so as to become the common method of lighting that the trouble will arise. There will come a time and a point when electricity will oust gas entirely, and the first opportunity may come any day. Distributing sub-stations will not solve the question, though distribution will really be the pivot upon which the solution turns. Meanwhile, the unit in any station should be so designed as to be working normally under full load. Our American contemporaries are struck by the load diagrams of central stations on this side showing what they kindly term Alpine Peaks, but they forget that the industry here has not so successfully induced users of small powers to employ electric motors as they have in some places on the other side of the Atlantic. We have always said too little attention is paid to power, and too much to light, but the argument against us is, Let us sell what the public want, and do not try to force that which they do not want.

TRACTION.

Elsewhere we describe fully Mr. Brain's conduit system for tramway work. It is truly hinted there that our adoption of electric traction is very slow, and that this slowness arises probably from the fact that the various plans adopted have not been the conspicuous successes their designers hoped. Accumulators, it is well said, have not so far obtained a footing. Cynical men say that really accumulators have never yet been tried. Certain samples—not altogether suited to tramway work, as working has shown—have, perhaps, been tried, but other and better forms have not had a look in. Some enthusiasts maintain that the best form of battery is one of the Planté type, that costs little, and may be worked out and thrown away for old lead. There is a good deal of plausibility in suggesting that a leaden battery costing, say, a couple of pounds, may be worked for six months, and at the end of that time go on the scrap heap for reworking up, its value for this purpose being thirty-five shillings. Accumulator traction has its field, on existing lines when self-contained cars are necessary or convenient. But it or any other system must be as economical as horse or mule traction. Sentiment is not business, and men will not, as a rule, pay a shilling for something they can get for tenpence. Again, overhead wires are not always obtainable though Glasgow seems to have come to the conclusion they may in certain places be tolerated. The conduit system will always command attention. If fairly cheap and efficient it possesses advantages over any other system, so that any new departure in this direction is sure of careful consideration. If, then, Mr. Brain has done all that he claims, he may be sure that any company entertaining the idea of electric traction will not fail to consider his plans.

VERDIER'S ACCUMULATOR.

Whatever the ultimate end of the lead secondary battery may be, it cannot be said that this type of electrical apparatus is being neglected by our present-day electricians. Our contemporary the *Revue Industrielle*, in a recent issue, contains a very glowing account of a new form of accumulator devised by M. F. Verdier, and which is constructed somewhat as follows: Litharge or minium, or other similar oxide of lead, is made into a thin paste by the addition of a vegetable oil or a mixture of glycerine and water. This pasty mass is then run into a frame or holder, made of some unoxidisable metal such as an alloy of antimony and lead. On being allowed to slowly dry in air, the lead salts become hard and of a cement-like nature. To increase the surface, and to allow for a free circulation of the electrolyte, all the plates are perforated vertically.

The plates are rendered active by being "formed" electrolytically in a bath consisting of sulphate of soda, or some alkaline salt which is soluble in a weak solution of glycerine and water. By this process the lead salts are reduced to the condition of spongy lead, and they are then fit to become the negative elements of the battery. The peroxide plates are said to be readily formed by immersing the reduced spongy leads, prepared as described above, in a bath of dilute sulphuric acid, and then subjecting them to electrolytic action for a few hours.

When building up complete cells the elements are disposed horizontally, that is to say, one above another, after the fashion of a Venetian blind. Insulating strips are placed between each plate, and the whole system of elements is held rigidly together by means of stout indiarubber bands. Connecting wires are carried from the metallic containing frames, which hold the active material, and those of like polarity are joined together by a suitable clamp, which forms one of the terminals of the battery.

Several types of the Verdier cell are made, and these contain respectively, five, seven, nine, and 11 plates. The elements in the nine-plate type, which is said to have a capacity of 400 ampere hours, weigh 20 kilogrammes, and each plate has a surface of 400 square centimetres. The elements in the 11-plate cell are smaller, and weigh collectively 6 kilogrammes, and have a current capacity of 125 ampere hours. The active surface on each plate of the latter cell is 100 square centimetres.

In the new cell it is said that the ratio between the active material and the gross weight of the elements may vary between 25 to 75 per cent., according as to whether the cell is constructed for high rates of discharge, or to withstand rough treatment. The ordinary commercial form of cell is stated to contain 60 per cent. of active material, and will give 20 ampere-hours per kilogramme of plate.

Some tests of the Verdier cell have been made by M. de Nerville in the Central Electrical Laboratory of Paris. From a test made on August 31st, 1891, the following results are taken: A cell weighing 6·8 kilogrammes, and containing five plates whose total weight was 2·4 kilogrammes, was fully charged and then discharged. The charging rate was one ampere per kilogramme of plate, and the discharge was made at 2·5 amperes per kilogramme. The result gave a current capacity of 32·08 ampere hours per kilogramme of element and with a fall of potential of from 2 to 1·85 volts.

Two other discharges of the same cell made with varying rates of charge and discharge gave the following results:

First Charge.

Mean rate of charge per kilogramme of plate.... ..	0·8 amp.
Total amount of current put in	81·5 amp.-hrs.

First Discharge.	
Mean rate of discharge per kilogramme of plate	1·0 amp.
Total current output	67·5 amp.-hrs.
Capacity per kilo. of plate	28·12 ,,
Second Charge.	
Mean rate of charge per kilogramme of plate	6·8 amp.
Total amount of current put in	85·0 amp.-hrs.
Second Discharge.	
Mean rate of discharge per kilogramme of plate	2·8 amp.
Total current output	58·5 amp.-hrs.
Capacity per kilo. of plate	24·37 ,,

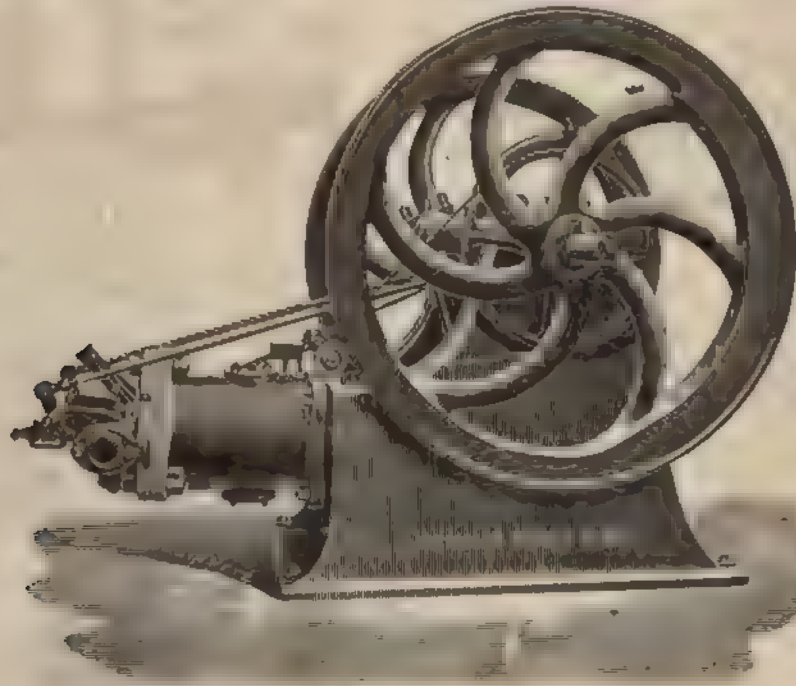

Fig. 1.

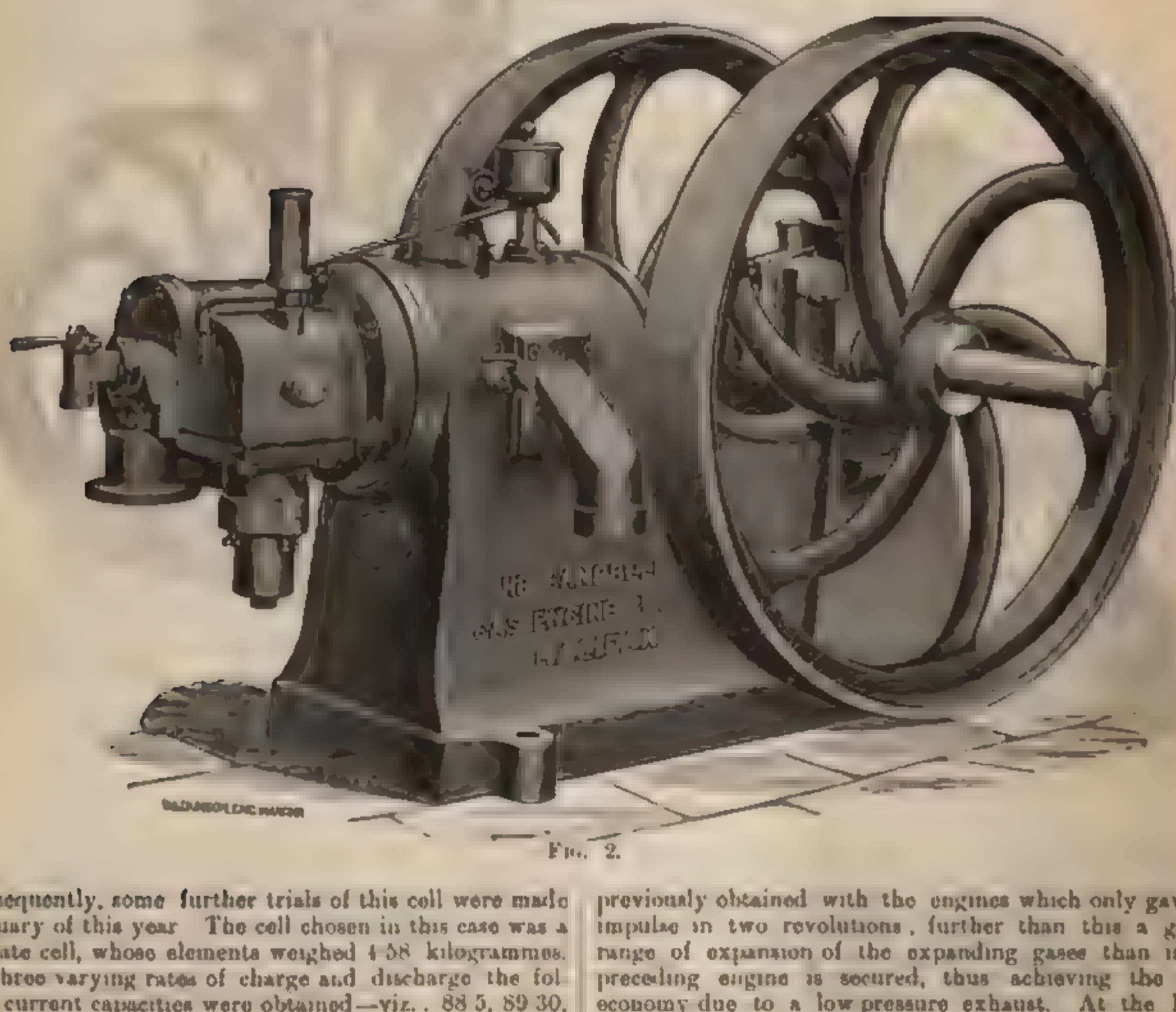

Fig. 2.

Subsequently, some further trials of this cell were made in January of this year. The cell chosen in this case was a nine-plate cell, whose elements weighed 4·58 kilogrammes. With three varying rates of charge and discharge the following current capacities were obtained—viz., 88·5, 89·30, and 92·0 ampere-hours respectively.

If these figures are reliable, there is yet some hope for the poor user of secondary batteries.

STEAM AND GAS ENGINES AT THE ELECTRICAL EXHIBITION.

Amongst the gas engines the cycle engine of the British Gas Engine Company will long remain one of the most mechanically interesting, on account of the mechanism by means of which four strokes of different lengths are obtained to one crank revolution, so that an impulse for every revolution of the crank is secured with all the advantages previously obtained with the engines which only gave one impulse in two revolutions; further than this a greater range of expansion of the expanding gases than in any preceding engine is secured, thus achieving the great economy due to a low pressure exhaust. At the Palace Exhibition two of these engines were employed in driving a number of lights, one of the engines is shown by the annexed engraving, Fig. 1, from a photograph. The prin-

ciple upon which this engine is constructed is one which in mechanical application differs from all others. Attempts have been made to arrive at similar results by simpler means, but no one has yet succeeded, and unless Mr. Atkinson takes the task in hand there does not appear to be much probability of its being accomplished.

The Campbell gas engine, of which several examples were shown, is a well made engine. An exterior view of one of these engines is given in Fig. 2, and

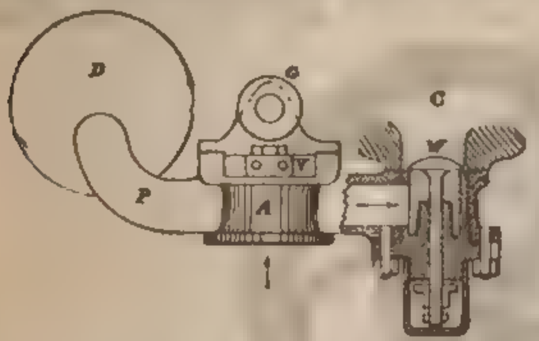

Fig. 3.

in Figs. 3 and 4 are views of the valve gear. The working piston of these engines receives an impulse at every revolution, a result which is secured by the employment of a second cylinder which, being provided with a piston, acts as a pump. This pump takes in a given quantity of air and gas, and on its instroke slightly compresses it and forces it into the working cylinder just as near the flywheel in Fig. 2. On its outstroke the piston in the pumping cylinder D, Figs. 3 and 4, draws in air through the chamber A and the pipe P, Fig. 4. On its way from the chamber A, through the pipe P, it passes through a port shown above A, Fig. 4, covered by the slide valve, V. When the engine requires a charge the finger F,

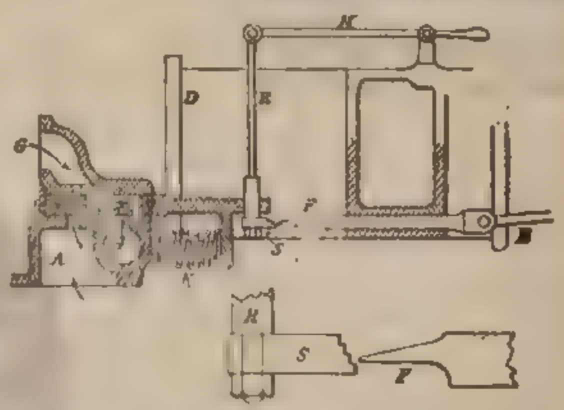

Fig. 4.

actuated by the eccentric rod E, comes into contact with the stepped piece S, which is held in a position, such as is shown at Fig. 4, by the governor rod R, which operated by the lever, H. The stepped pieces and finger F are shown to an enlarged scale below, Fig. 4. When the engine requires a full charge—such as it would get with the step-piece raised to the position shown—the air port

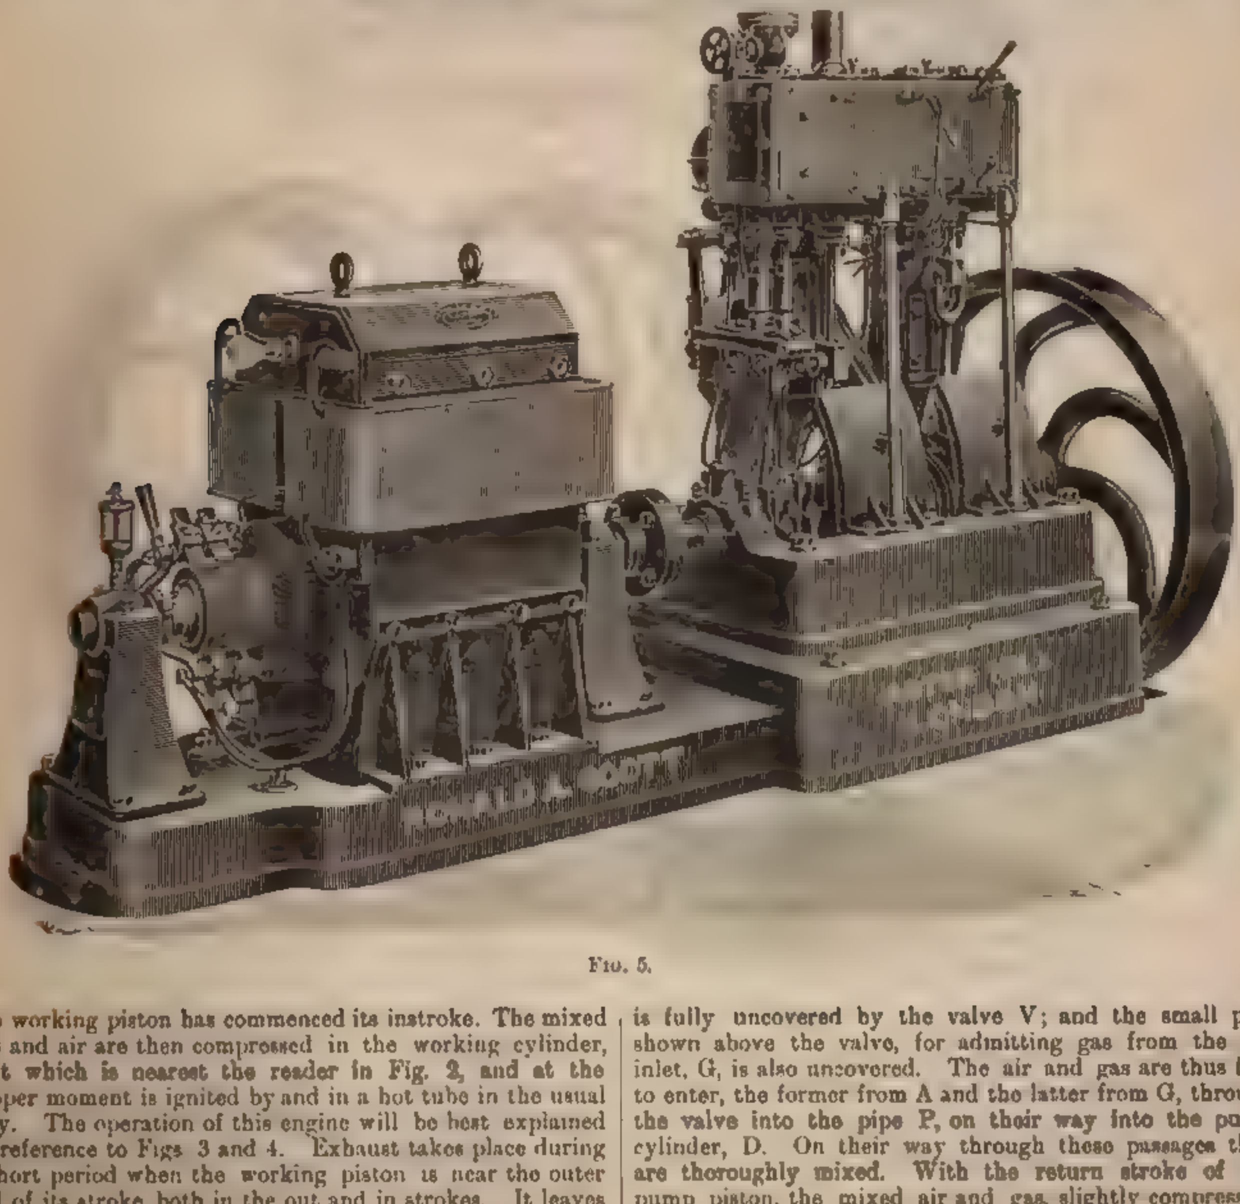

Fig. 5.

the working piston has commenced its instroke. The mixed gas and air are then compressed in the working cylinder, that which is nearest the reader in Fig. 2, and at the proper moment is ignited by and in a hot tube in the usual way. The operation of this engine will be best explained by reference to Figs. 3 and 4. Exhaust takes place during a short period when the working piston is near the outer end of its stroke, both in the out and in strokes. It leaves the cylinder by a port covered by the exhaust nozzle, seen is fully uncovered by the valve V; and the small port shown above the valve, for admitting gas from the gas inlet, G, is also uncovered. The air and gas are thus free to enter, the former from A and the latter from G, through the valve into the pipe P, on their way into the pump cylinder, D. On their way through these passages they are thoroughly mixed. With the return stroke of the pump piston, the mixed air and gas, slightly compressed, pass through the pipe P and into the working cylinder

through the valve W. The relative positions of the working and pump pistons are so chosen, that the charge from the pump enters the working cylinder before the exhaust-valve closes and has time to drive out some of the residual products of combustion. Those products which remain do no harm, because they are next the piston and do not affect the combustion of the explosive charge. The governor of this engine is of simple form, but is not shown in our engraving.

Mr. Ronald A. Scott exhibited the combined engine and dynamo, as shown by Fig 5. They were employed in supplying current to two powerful search lights, experiments with which attracted a great deal of attention. The combined plant is for 12 units output—150 amperes at 80 volts and were fixed in stand No. 47 in the Machinery Court. This is a very compact little plant, and the good governing is attested by the varied load put on. In addition to the search lights, the dynamo supplied 16 incandescent lamps and two motors, and occasionally a third search light. The engine is one of Messrs. Davey, Paxman, and Co.'s compound vertical "Windsor" type engines of about 25 i.h.p., fitted with Paxman's automatic expansion gear, and runs at 280 revolutions. The dynamo is constructed with fieldmagnets of soft wrought iron machined all over, and with a section of 133 square inches. The magnetic leakage is reduced to almost *nil* by mounting the field limbs on gun-metal brackets, at a distance of 6in. above the iron bed-plate. The armature is drum wound, and consists of 192 copper bars with end connectors, and a commutator of 96 sections. The end bearing is mounted in a spherical self adjusting plummer block, and the bearing surface is Magnolia metal. The floor space occupied by this coupled plant is 8ft. 6in. by 3ft.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

I.—EVOLUTION OF ELECTRICAL ENGINEERING.

Repeal of the Act of 1882.

The repeal of the Electric Lighting Act of 1882, which was chiefly brought about by the efforts of Lord Thurlow in 1888, marked the beginning of a new and bright future for the electrical industry. Hitherto, its progress was terribly burdened by the old Act, this Act was hastily passed and put into force by Parliament in 1882, during the electric light mania, and was intended to protect the public against the wild and indiscriminate investment of money in swindling companies that were floated by the dozen. The protection took the form of empowering the local authorities to purchase the plant of the enterprising company at the end of 21 years, whether the company were agreeable or not, without being bound to pay the latter anything for the goodwill or source of profit, or increase of value, of the undertaking. But the bane of the Act was soon felt, for it totally crippled the electric light industry, so far as public supply was concerned. The golden stream ebbed back from an industry that was made so doubtful of remuneration, and electric lighting was starved through want of capital. Yet it is said that "out of evil comes good," but the only good apparent is that whereas a few years ago towns might have had poor and ill designed plant put down, now electric plant and apparatus has reached a high state of perfection, the light and the system of distribution is better understood, and lastly, the advent of the high tension alternating-current system has supplied a wonderfully elastic means of distributing light and power over large areas, a problem which cannot be well solved by low tension currents. The repeal of the Act in 1888 increased the term of compulsory purchase to a period of 42 years, thus doubling the length of time, this was the chief alteration, and it was one of incalculable value to the industry. The immediate effect of this acted as a great fillip, and the dormant energy that had been extant, soon showed itself in four short years. The increase of the electrical trade has been phenomenal, and the basis of a new and important industry firmly established on sound foundations.

Electricity in England and Abroad.

Let us look around and see what position electricity occupies, and what progress it has made in various parts of the world; no account will be taken of the telegraphic or telephonic industries, but only the utilisation of electricity for lighting and motive purposes.

America takes the first place in the electric light and power industry, the towns there being lit up by the score, and there are very few towns indeed that do not possess a central electric light and power station for distributing same, the electric light over there being as prevalent as gas. They adopt a better standard of light, but we in England are accustomed to have a few dim gas lamps every 40 or 60 yards, which just suffice to make darkness visible. Probably the Britisher thinks it is a vast improvement to have light of any description in the streets of a town, for a century ago towns had no light scarcely, except what was eked out by the dismal oil lamp. An American reckons a good street light as valuable as a policeman, and no doubt he is right.

Coming now to the application of electricity as motive power, there are now above 450 tram lines worked by electricity, having a total length of track of 3,600 miles, and employing upwards of 6,000 motor cars. During the last year 250,000,000 passengers were carried, the aggregate number of miles traversed being 50,000,000, and the amount of capital invested was 60,000,000dols., or £12,000,000.

The following figures show the extraordinary development of electric tramways:

Year	Lines.	Motor cars
1884	1	
1885	3	13
1886	5	39
1887	7	81
1888	32	265
1889	104	965
1890	126	2,000
1891	405	5,100
1892	550	7,500

The above statistics refer only to one system or method of working the lines, that known as the "overhead system," because the car receives its current by a trolley wheel rubbing along a wire suspended over the top of the car. This is the system mostly adopted in the States, although there are a number of other lines worked on other systems, such as by accumulators, etc., and of which no figures are given. By far the greater part of the overhead system is run by two companies, the Thomson Houston and the Edison.

The Thomson Houston work 231 lines, and supply 4,575 motor cars for 2,642 miles of road, while the Edison run 179 lines, and supply 2,100 motor cars. The rest is run by several minor companies. It may be mentioned that the system used by the Edison Company is that known as Sprague's.

The greatest tramway, or street railway, system in the world exists at West End, Boston, Mass., originally worked throughout by horse power. Electricity is fast superseding horseflesh as a motive power, and in the summer of 1891 one fourth of the entire mileage was worked by electricity on the Thomson Houston system, 542 motor cars working over 112 miles of road, and before long the whole will be worked by electricity.

To show how matters electrical thrive in Yankeeland it may be mentioned that the capital of the Thomson Houston Company stands at 10,000,000dols., or £2,000,000, and is credited with being the most powerful electric company in the world; and since one half of the total arc lamps in the States are supplied by this company, and the same with regard to the electric traction plant, not much more can be desired as proof. The rise and growth of this enormous concern well illustrates in a practical and commercial sense the phenomenal advance of electrical science, just as the prosperity of a manufacturing nation is judged by the quantity of sulphuric acid it consumes. In 1885 there were only about a couple of hundred men employed, now the works at Lynn, Mass., employ no less than 4,000 to 5,000, and the valuation of plant erected by them in the States comes to something like 70,000,000dols., or £14,000,000, distributed over 700 central stations.

The Edison General Company follows close behind the

Thomson-Houston in magnitude and importance, and the great event in electrical industrial circles has been the amalgamation between these two great companies: this was effected in the beginning of 1892, and thus forms a gigantic electrical trust, with a capital of 50,000,000dols., or £10,000,000, capable of controlling a monopoly of the greater part of the electric industry in the States.

A great problem now occupying the attention of electricians and engineers is the utilisation of the Niagara Falls, millions of horse-power there running to waste year after year. Hitherto this vast source of power has been unavailable, and its utilisation to produce electricity will be one of the greatest practical achievements in the domains of electrical science. It is proposed to transmit the electricity generated to Chicago and other large towns, there to be employed in lighting the streets and houses, driving machinery, propelling street cars, etc.

Turning our attention towards our own country we cannot but be struck in observing the disparity existing between the two. London is the only place where electricity enters to any degree into the commercial world; even in the largest city in the world, the heart and core of business and finance, the light is confined to the wealthy classes, so far as private dwellings are concerned, although it is freely used now in theatre, restaurants, hotels, clubs, etc. Still it must be admitted that enormous advances have been made in London during the last three years. Since the repeal of the Electric Lighting Act of 1882, every district in the metropolitan area is allotted out to some electric light company, and, furthermore, every district has now got a central station put down and at work. Whatever the English do, they do thoroughly and solidly, choosing their own time and weighing everything carefully before committing themselves, and as the individual is, so is that larger individual, the corporation or local authority, but when once on the move, nothing but the most substantial and approved work will suffice.

A short time back the towns possessing central stations could almost be counted on the fingers. A great wave of electrical activity has now begun to pass over England, and city after city, town after town, is up and doing. This activity among local authorities, etc., has broken out suddenly like an epidemic, and it will not be very long before England leaves America far behind, if comparison be made on the score of size.

The lighting of the City of London was a great and decisive step towards showing that the time had arrived for local authorities to seriously consider the advisability of adopting the electric light as a better means of illumination. The lighting by gas in the City gave an aggregate of 35,000 c.p., the ordinary jets used being about 14 c.p. to 16 c.p., while the larger jets gave about 40 c.p. to 50 c.p., five cubic feet per hour being consumed by the small jet, and 15 cubic feet per hour by the larger jet. The above quantity of light is now being replaced by arc lamps of 1,000 actual candle-power in the main thoroughfares, and by incandescent lamps of 25 c.p. to 50 c.p. in the side streets, alleys, etc., The increased cost of lighting by electricity is almost double that of gas, but it must be remembered that in the former case much more light is given. The undertaking is in the hands of a company which was formed to take over the concessions granted to two eminent electrical firms—namely, the Laing, Wharton, and Down Construction Syndicate, and the Brush Company; the former using their Thomson-Houston system, and the latter using the Brush system. Besides the street lighting, a compulsory area is mapped out, and mains for private house supply are bound to be laid down in this fixed area within a definite time. The private supply is by high-tension alternating currents, this method being adopted by both the above contracting firms on their respective systems. The City is divided into three districts; of these the Thomson-Houston system is used in the eastern district, which is east of the Mansion House, Princes-street, and Moorgate-street, where the private output will be for 4,800 kilowatts, or over 75,000 glow lamps of 16 c.p., and the street lighting for 900 arcs, while the Brush system is used in the western and central districts.

In London the Vestry of St. Pancras has the honour of being the first to adopt the electric light in the streets in place of gas, and also the first local authority to erect a central electric light and power station, supplying current both to their own street electric lamps and to the private houses. The streets are lit by 90 arc lamps of 1,000 actual candle-power, of the Brockie-Pell type, and placed at distances varying from 160ft. to 245ft. apart, suspended on steel poles 25ft. high. The private supply to householders is met by having machinery capable of running 10,000 glow lamps of 16 c.p. each, the whole output of which was taken up within six months after erection of the station.

The following tabulation shows the number of lights used in London:

Company.	Lamps in use, 8 c.p.
London Electric Supply	90,000
City of London Electric Light	23,000
Westminster Electric Light (three stations)	137,000
House-to-House	25,000
Chelsea Electric Light	30,000
St. Pancras Vestry	10,000
Kensington and Knightsbridge (two stations)	50,000
New Cadogan	10,000
St. James and Pall Mall	60,000
Metropolitan Electric Light	97,000
Electricity Supply	25,000
Total	557,000

The subject of lighting in London cannot be left without mentioning the gigantic scheme at Deptford. There Mr. Ferranti, the originator, contemplates using engines and alternators of 10,000 h.p. to transmit electricity from Deptford to London, at an electrical pressure of 10,000 volts, three trunk lines being used, which pass over the river by way of three railway bridges, thus feeding three different points. The 10,000 volts at these three points are then transformed down to 2,500 volts, at which electrical pressure the distributing mains are worked. A second transformation down takes place before the current enters the consumer's house, where it is brought down to 100 volts, the usual voltage for glow lamps. The magnitude of the scheme may be imagined when it is stated that the generating plant will be, when fully equipped, sufficient to feed 2,000,000 glow lamps. Unfortunately an ambitious undertaking like this, on such a vast scale, presents enormous difficulties, which swallow up a great amount of time and money, but the London Supply Corporation have stuck well to their guns throughout, believing firmly in their talented engineer, and, in spite of the disasters which have overtaken them, success is already beginning to crown their efforts.

The demand for current in some districts, for a long time has greatly exceeded the supply, as the various companies cannot extend their mains quickly enough. Some householders have had their houses ready wired for months, and, like Patience on a monument, wait until the supply company's mains get laid near their door. Great complaints naturally arise from this; sometimes it is the fault of the supply company through backward state of work, but mostly it is due to the importunate solicitations of the house-wiring tout, who, to secure the order for wiring, victimises his hoped-for customers by assuring them with the most barefaced plausibility that the supply mains will be down at his door by the time the house is ready. The householder is, therefore, strongly advised to take timely warning. Before putting your house into the hands of any stray individual, first see that the supply mains are already laid down, or being laid down close by you, or, at all events, within such a distance that the supply company, upon being asked, will join you on, then, and not until then, you may have your house wired without experiencing any of the heartburning and vexation in spirit from which so many are at present suffering.

In the provinces progress is not so rapid, yet there is a steady increase going on which is very satisfactory. Several of our large towns, such as Dundee, Glasgow, Bristol, Portsmouth, Nottingham, etc., have voted large sums of money for the establishment of central electric light and power stations.

Corporations, as is well known, are slow to move, and probably most of them have been waiting to see what the metropolis would do; now that the centre of the metropolis, the City, and the Vestry of St. Pancras have the streets publicly lit, the provincial authorities are beginning to think they can safely follow in their wake.

(To be continued.)

BADT'S ALTERNATING-CURRENT ELECTRIC RAILWAY SYSTEM.

The apparatus for conveying power to electric motor cars by underground conductors, which is illustrated by the accompanying cuts, is the invention of Lieut. F. B Badt, of Chicago, who proposes to use alternating or multiphase currents for this purpose. It is proposed to transform the current in step-down converters located at short distances apart, using two surface conducting rails, connected with the secondary coils of the transformers, to conduct the current to the car motors by rolling contacts. It is, however, possible to make one transformer answer for a considerable extent of track by using suitable switching arrangements. The conductors are to be laid in sections insulated from one another, and an automatic switch is provided by which the rails next in advance of the car will be thrown into circuit in time to furnish the working current as soon as the car has moved over them in the proper position, and cutting it off after the car has passed By this device, it is claimed, the conducting rails will only be in circuit at the time of the passage of a car.

Fig. 1

Fig. 1 gives a diagrammatic view of the parts of the apparatus in their relative vertical positions, while Fig. 2 shows an enlarged detail of a transformer and its associated parts. Referring to these cuts, A is an underground cable containing two conductors. The cable proper is composed of successive sections, each of which is securely let into the side of the box E by means of the stuffing-box, D. Within this box the main conductors are bared, and from them lead the terminals of the primary coil, F, and in opposition to the secondary coil, H, whose terminals led through stuffing-boxes into the switchbox, K. The two cover-boxes may be tightly filled by means of the funnels, L L, with oil to assist insulation In the box K is located the switch consisting of an electromagnet, M, which is included in the local circuit composed of the conductors, M[1] M[2], leading, respectively, from the sectional rails, M[4] M[4] (Fig. 2)

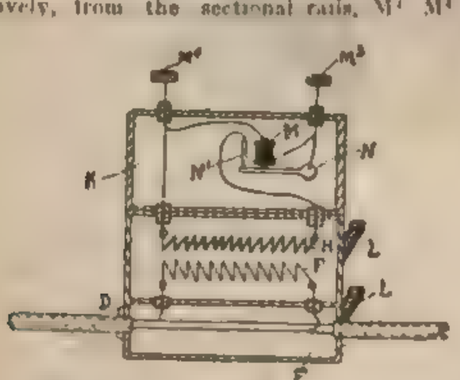

Fig. 2.

Opposed to this electromagnet is the pivoted armature, N, normally disengaged from the contact block, N[1], which forms one extremity of the conductor which leads from the secondary converter coil The other conductor, O (Fig 1), from the secondary leads to the sectional rail M[4]. The armature, N, may be held away from the contact point N[1] by spring, gravity, or otherwise as may be convenient. The rails M[4] M[4] are made in successive fairly well insulated sections laid upon the surface. These sections are, preferably, slightly less in length than the distance between the trolley wheels, R R and S S.

In the underground cable it is proposed to use currents of 2,000 volts potential, or higher if desired, to be transformed down to 50 volts. If for any reason the local circuit is closed, no particular loss of current will ensue, for insulation sufficient to confine a current of such low voltage in the sections of conducting rail can easily be obtained. Moreover, if by any possibility a local short circuit should be completed, small damage, if any, would be done on account of the low voltage of the local current. Suitable fuse-plugs would be placed in any or all of the circuits or connections, as desired, for the purpose of ensuring safety, and the car is preferably provided with two motors, though more or less could be used, and with two sets of trolley wheels. One set will be placed forward on the car and the other toward the rear. The conductor rails or strips are preferably arranged between the tracks or rails on which the car is supported and consist each of successive sections insulated in the ordinary manner and so far as may be convenient from each other.

Various means may be devised for closing the switch in the first instance to start the car, as, for example, a storage battery cell or two may be associated with the car. Assuming that current taken up by the forward trolleys is being passed through the motors on the car and through the magnet of the switch to hold its armature up and the circuit closed, the car will, of course, tend to move forward under the action of its motors. Its forward motion speedily carries the forward trolleys towards the next succeeding set of conductor rails or strips. The rear trolleys will, however, at such time necessarily be on the set of rails or strips in the rear of those against which the forward trolleys act. This current is being supplied to operate the car and to keep the rear rail sections in circuit through the rear trolley. At the same time the forward trolleys, being connected, as shown, with the rear trolleys, a circuit is closed through the switch associated with the next converter, and a sufficient current is diverted through such circuit to close the switch or lift up the armature and complete the circuit through the secondary coil of the forward converter. This brings the forward trolleys into circuit, and they lead a current through the motor or motors of the car. When the rear trolleys pass off of the set of conductor rails on which they are acting, they will of course cause the release of the switch and the local circuit connected with these rails will be broken; but before this action takes place, since the conductor rails are somewhat less in length than the distance between the trolleys, the forward trolleys will have passed on to the second successive or forward conductor rails, and will have brought them into circuit, and the current will be supplied through them, as last above described.

The system with some modifications is applicable to conduits already laid. Lieutenant Badt has also devised a mechanical switch for this system by which the current is turned on and off by means of projecting pins from the trolleys. The advantages of the invention are the absence of overhead wires, the presence of the current in the surface conductors only when the car is over them, and the low voltage employed in these rails. The principal defect of the system is the lack, at the present time, of a satisfactory alternating-current motor adapted to street car work, but when this want shall have been supplied Lieutenant Badt's invention will no doubt be thoroughly investigated by practical tests.—*Western Electrician.*

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION *

BY PROF. GEORGE FORBES.

LECTURE I.

(Continued from page 244.)

CENTRAL STATION SUPPLY v. ISOLATED PLANT

At the date of my previous Cantor Lectures the great questions before our minds was whether central stations were economical. It was obviously far more convenient for the public to be supplied from a general source than for each one to generate his own electricity; in fact, the latter plan would be impossible, except in the case of large establishments. It was further obvious that the cost of both labour and coals in small plants would be far

* Cantor Lectures delivered before the Society of Arts.

greater than in a central station. But the fact remained that, with central stations, we had all the additional cost of mains run through the streets, involving enormous cost, not only in copper, but also in taking up streets, finding a way among all the underground pipes, and making all good again. We had just learnt, from the experience of the telephones, that the more subscribers there were after a certain limit, extending to greater distances, the less dividends could be paid. Consequently there were many men at that date who did not think that central stations could compete against isolated plants for even moderate sized establishments, and who saw no prospect of small consumers being supplied, except by neighbours clubbing together to generate electricity for themselves.

Fortunately the verdict has hitherto generally been that current can be economically generated in, and distributed from, central stations, and the proof is in the enormous ramification of electric circuits now occupying the beds of the streets of London. I do not know the case of any town in the world where such enormous progress—designed for permanency—has been made in so short a time. From 1882 to 1889 the legislative enactments restrained and held, as in a leash, the spirit of the age—which is electrical. In the last-named year, Major Marindin, acting for the Board of Trade, held the great inquiry in London, besides minor ones in other towns, as to what powers were to be granted to what companies. From the moment that his reports were accepted, the forces which had so long been restrained burst forth, and the pioneers, like released greyhounds, darted after their prey, and the whole place was in the hands of the electricians. All the work was well done, and will remain; and we may well be proud of what has been accomplished.

But while thus congratulating ourselves, we must not overlook the fact that we are prevented by several causes from supplying electricity so cheaply as might be hoped. I have already given you the figures with respect to one large club, and I could give you many others to show that at present, for a large establishment using light for long hours, an isolated plant is the cheaper. It is particularly to be remarked that the average number of hours that a light is in use is barely two hours a day. Hence, during the greater part of the twenty-four hours, the mains in the street are lying practically idle, the boilers and engines are earning no dividend, while the managing staff would have no more work if all the customers used the light for longer hours. Hence, during the greater part of the day, the cost of producing an additional electric Board of Trade unit is little more than the cost of the coal, certainly not 2d. a unit, while for a few hours in the evening it is at least three times as much. You see, then, how hard a fixed price per unit is on clubs and other places where a steady large supply is wanted for long hours. This is one reason why the public supply to the Athenæum Club would cost £500 more than the cost of making it on the premises. This is why the cost of an electric arc lamp for street lighting would be double what it would if not obtained from a supply company. If we had any means of supplying electricity for a short time as cheaply as at the full output all the 24 hours, we should reduce the selling price to one-third of what it is now.

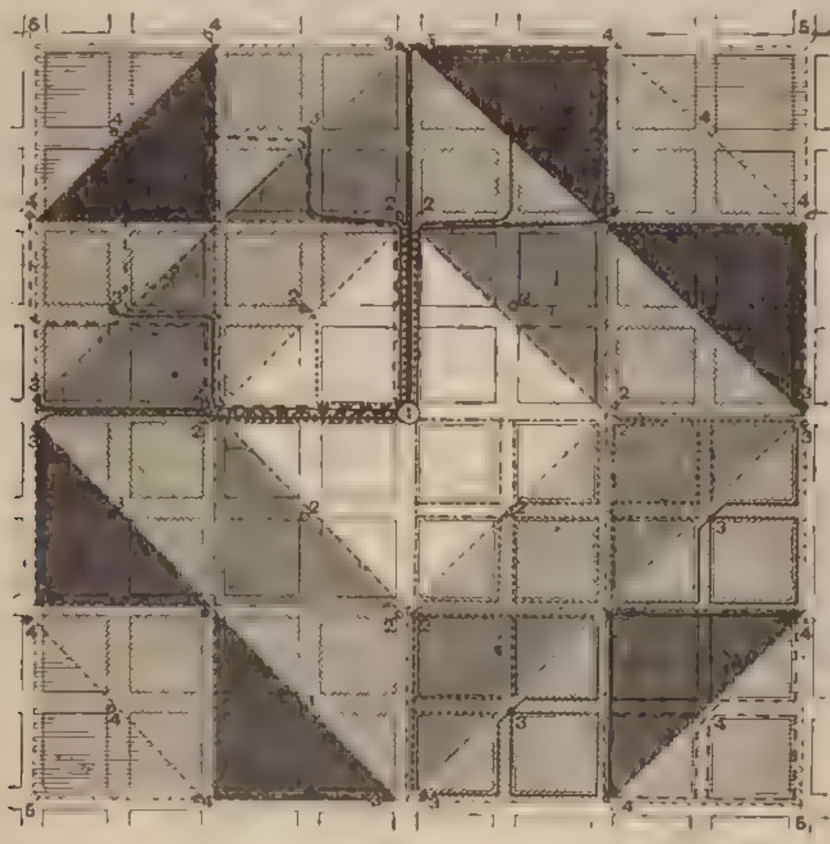

FIG. 1

ELECTRICITY *v.* GAS.

At the present time electricity in towns often costs twice as much as gas, and it is not everyone who can see that the gains counter balance the extra expense. It certainly saves expense in decoration, it is far more healthy, and in valuable buildings like the British Museum, it alone can be permitted as giving absolute immunity from fire where properly carried out. The same remark applies to all private houses. When a curtain or a dress is blown by the wind or otherwise brought into contact with a gas jet we have a fire. When this happens with an incandescent lamp we have absolute immunity. But by taking advantage of the facility of putting out a light in a bedroom when done with, great economies can be effected in careful households. There is one case in which electricity beats gas and other illuminants, not only in cleanliness, health, and security from fire, but also in economy, and that is in country houses. I could bear this out by numerous examples. One large old castle in Scotland, where the risk of fire was great, and the electric light was introduced primarily for security from fire, offers a good example. Here there are 210 lights of 16 c.p. installed, the house has always been full, and the lights much used. The installation cost £1,800, and last year, the second of working, an accurate note of all the expenses, labour, coal, etc., comes to £75. Nothing approaching to this could have been got from gas manufactured on the premises, and, at the rates charged by supply companies, the cost would have been over £300.

Feeders and Distributing Mains.

The satisfactory working of a central station depends largely on the proportion that the feeders bear to the distributing mains. Some stations have been started by persons quite incompetent to do the work, and have no feeders at all. The consequence is that we have enormous variations in the pressure at different times. I believe that at Brighton there is at times of maximum working a difference of pressure in lamps on different parts of the circuit amounting to 25 volts, and instead of applying the well-known engineering methods, it has been attempted to patch it up by putting lamps of different voltage on different parts of the system. When such a thing is attempted, except for the correction of a very few volts, we are landed in worse trouble. I would draw attention to the diagram on the wall, Fig. 1, representing the plan of an American city like Philadelphia, and showing the way in which the feeders and distributing mains would be run for lighting the city with economy, and confining the variation of pressure all over it within the same limits. The centre square, shown white, would have no feeders, but be divided up into four triangular-shaped districts, each being supplied by mains from the central station. The part between the feeding points marked 2 and those marked 3, would be divided up in the same way into triangular shaped districts, and each have its own feeder, and distributing mains starting from a No. 2 feeding centre; and so on for the districts outside these. It will be noticed that all the distributing mains starting from the feeding points are of equal length, if measured along the streets, as shown at the bottom right-hand corner of the diagram. The circuits being run in this way, a network may be formed by connecting the ends of the distributing mains together wherever close, and whichever district they belong to, since the pressure at these points will always be nearly the same—assuming the same current density in all the distributing mains, of course. I sent out a circular lately to try to find out how far the benefit of feeders was appreciated in our central station engineering, but very few supply companies cared to give the information. I find that the Kensington and Knightsbridge Company have:

	tons	cwt.	qrs	lb.
Total weight of mains	153	11	3	5
Total weight of feeders	15	10	3	0

in a total length of street covered = 12 miles 835 yards, partly copper strip, insulated by glass insulators, supported by oak bars, being used; and partly vulcanised rubber cables run in iron gas pipes coated with Angus Smith's composition.

The cost for straightforward work under foot pavement, including material, wages, superintendence, digging, and carting away, but not tools and spare plant, is stated to be:

	Per yard £	s.	d.
Five pipes, four of 2in., and one of 1½in., with three cables $^{19}/_{15}$, and two cables $^{7}/_{11}$	3	2	2
Three pipes, two of 2in., and one of 1½in., and three $^{19}/_{15}$ cables	1	8	6½
15in. culvert, including three strips 1in. × ⅛in.	1	3	9
20in. " " five " " "	1	9	0
24in. " " seven " "	1	14	2

The number of lamps supplied up to January 6, 1892, is equivalent to 38,680 of 8 c.p. The h.-p. available is—

Kensington court	1,070
Chapel place	700
	1,770

The total capital invested in mains of all kinds, including copper and cable, is 33 per cent. of £133,000, the total paid-up capital; in machinery and buildings 43 per cent., and in batteries 10 per cent.

At Chelmsford, with alternating currents, overhead wire is generally used, ¾ ton for street lights, 1½ ton for secondary wires, and one ton for primaries for private lighting. Indicated horse-power in station, 300; total outlay, £14,000. Lamps, 220 of 32 c.p., 1,000 of 8 c.p. for private use, 19 arcs of 10 amperes, and lamps in works using 180 amperes and 110 volts. Welsh coal per unit generated 8·8lb.; efficiency of an engine and dynamo, 75 per cent. (mean).

The Westminster Electric Supply Corporation's distributing mains are estimated roughly at two to two and a half times the weight of the feeders. The total capital of this Corporation is £300,000, the total indicated horse-power in central stations 3,500, and the number of lamps supplied equivalent to 66,000 8 c.p. The cost of mains and underground work is roughly £150,000, and the total length of pavement opened up is 53,640 yards. In places, the mains consist of bare copper in concrete culverts; but the Corporation have by far a greater length of insulated cable laid in Callender casings.

(To be continued.)

HASTINGS.

The town authorities have, as they ought to have done, determined to light the sea front by means of the electric light. The determination was not made without a struggle, as will be seen from the report of the meeting:

The Public Lighting Committee had to report that they had under consideration the matter of the desirability of extending the electric light on the Front line. They had been in communication with the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, on the subject, and had ascertained that the company were prepared to enter into a contract with the Corporation for the lighting of the Front from the Fish Market to the end of West Marina, for a period of three years, by means of 32 arc lamps, placed about 50 yards apart (instead of 100 yards, the distance between existing electric lamps), the whole of the lamps to be lighted from sunset to 12 midnight, and after that hour each alternate lamp to be extinguished, and the other lamps to be kept alight till sunrise, the company undertaking to maintain a steady light, free from extinctions, at £25 per lamp per annum, the contract to commence as soon as the company had made the necessary additions to their machinery (which, the committee were informed, would be of the latest and most improved type, and duplicated to prevent any failure in the supply) and extended the mains, etc. The committee had fully discussed the company's offer, and had received from the borough surveyor a report prepared by him, in accordance with their instructions, for their guidance and information on the subject, and under all the circumstances recommended that such offer as above set forth be accepted, and that the town clerk be authorised to affix the common seal, in due course, to the necessary formal contract with the company.

Councillor Duke moved the adoption of the report. He detailed all the propositions as contained in the report, and dilated upon the necessity of having either gas or electric light instead of both, as at present. The present cost per electric lamp was £30 per annum, which meant a total expense of £450 per annum for the whole; whilst the proposal, if carried out, would secure each lamp at £25 per annum. The space between the Fish Market and West Marina was at present lighted by 15 electric lamps, 69 Whitehalls, and 43 ordinary single burners, and the total cost was £1,038. The new electric lamps would have no arms that would throw a shadow, as did the present ones. Comparing the proposed electric lighting with that used at present, there would be a great advantage in candle-power. To light the Front with Whitehall lamps, placed 40 yards apart, 98 would be required, at a cost of £1,046 12s. 4d. per annum, whilst the proposed system would cost £1,300, or about £250 more than the other. They were all sensible of the excellence of the Whitehall lamps, but he felt that the ratepayers and the public generally would not be best pleased by the electric light being done away with. With regard to the question of the Corporation having its own light works, it was proved that they could not supply light so cheaply as they could get it from the electric light company.

Councillor Elworthy seconded, and said that there was one thing certain, and that was they could not take a retrograde step, as the electric light was the illuminant of the future. It was acknowledged by all hands that the present lighting was bad; anything more miserable they could not conceive. At the present time the electric light was put out at 11 o'clock, and then the gas was reduced to half its power, which put him in mind of the miserable condition of affairs they experienced in that part of London in which he lived when a boy, and when the oil lamps were used. What they had to consider was the difference of the power of the two lights. He had made a calculation of the difference of the power, and he found that the maximum electric light would give a light six times as great as the gas, and the difference in the mean light was four times as great. When they took into consideration that after 12 o'clock only half of the lamps would be lighted, that would mean having six times as much light as they got at present from the gas. The company had agreed to put down a separate main for the lamps and had guaranteed, when the new machinery was erected, to give a continuous steady light. The lamps would be 50 yards apart, and he had made a test and had come to the conclusion that there would be no dark space between the two lamps. He thought the alteration would be a great improvement to the town, and hoped that the resolution would be carried.

Councillor Ellis said up to noon of the previous day he favoured the alteration, but then he was given certain information which

had put a different complexion upon the case. In the matter he was a layman, and had to be guided by the advice of men who were qualified to give definite information upon the point. He had a great respect for the opinion of their surveyor, who was an engineer, but another gentleman he had met, whom he equally respected as an engineer, formed quite a different opinion to that of Mr. Palmer. The two gentlemen greatly differed as to the illumination they would receive from the electric light, and before any decision was arrived at he thought it would be better that an independent engineer should be asked to make a thorough test, and report to the Council.

Mr. Palmer remarked that the gentleman who had given information to Councillor Ellis was an interested party.

Councillor Ellis said he had as much confidence in one gentleman as the other, but he did not wish to take a leap in the dark.

Alderman Jenner, Councillors Stanger and Wright, Aldermen Bray and Bradnam, Councillors Shoesmith, Eaton, Tuppenney, and Duke all joined the discussion. Ultimately the resolution was put to the meeting, and the following voted in favour of it: Councillors Duke, Tuppenney, Wright, Pigott, Chapman, Shoesmith, Eaton, Sutter, and Elworthy. Those who voted against it were: The Mayor, Aldermen Jenner and Bradnam, Councillors Hutchings and Stanger. Councillor Ellis did not vote. Alderman Bray, Councillors Stubbs, Weston, Slade, and Ellis, being shareholders in one or other of the companies, could not vote.

LEGAL INTELLIGENCE.

THE ST. BENET FINK AND ST. NICHOLAS COLE ABBEY FACULTIES.

Transformer Chambers for the Electric Light.

At a sitting of the Consistory Court of London, held on the 3rd inst. in St. Paul's Cathedral, before Dr. Tristram, Q.C., Chancellor of the Diocese of London, who was attended by Mr. E. W. Lee, the registrar, the **Chancellor of London** delivered judgment in these cases, as follows: On Monday last, the 29th ult., application was made to this Court to authorise by faculty the construction of transformer chambers or vaults in two City churchyards long disused for burials—one in the churchyard of St. Benet Fink, close to the Royal Exchange, and the other in the churchyard of St. Nicholas Cole Abbey, in Queen Victoria-street—for the use of the City of London Electric Lighting Company, Limited, to enable the company to introduce the electric lighting into those parts of the City in which the churchyards are situated. The construction of these chambers will involve the disturbance of human remains and their removal and reinterment in some other consecrated burial ground. The petitioners for the faculty for the construction of a chamber in the churchyard of St. Benet Fink are the Mayor and Corporation of London and the rector and churchwardens of the parish, and the petitioners in the case of St. Nicholas Cole Abbey are the rector and churchwardens of the parish. Each of the applications is supported by resolutions of the vestries of the respective parishes passed unanimously. Certain of the facts adduced by the petitioners in support of the granting a faculty are common to both applications. It appears that the City of London Electric Lighting Company was established by Act of Parliament with the object of lighting the streets, offices, and houses in the City with electric lights, with a nominal capital of £800,000. The company, in furtherance of this object, has during the last 12 months expended £350,000, and has contracted with the Corporation of London to light the streets of the City for an annual payment of £20,000 on the completion of the system. The church and site and the churchyard of St. Benet Fink were by a local Act of Parliament, 5 and 6 Vic., cap. 101, vested in the Mayor and Corporation of London, with a view to extend the avenues adjoining to the Royal Exchange, and a portion of the site was appropriated under the Act for that purpose. The Act provides that as soon as the "said church and burial ground shall be cleared for the purposes of the Act, the mayor, aldermen, and commons in common council assembled shall cause the same, except such part thereof as shall be laid into the streets or public ways or appropriated for parsonage houses, as in the Act mentioned, to be enclosed by a substantial iron railing or other substantial fence, and the residue of the said site and burial ground shall remain for ever unbuilt upon and unappropriated to any purpose except such ornamental purpose as the said mayor, aldermen, and commons in common council assembled, with the consent of the Bishop of London for the time being, signified by writing under his hand, shall think fit to direct." By this section the Court is precluded from dealing with the site of the churchyard, and by the Act the Corporation have now no power to deal with the vaults underneath the site, and the vaults being in consecrated ground this Court has jurisdiction to make such orders in relation to them as the circumstances of the case may require. The question is whether it has under the circumstances of this and the next case discretionary power to make the orders asked for. In support of this application, the following facts appeared in evidence: By the construction of the chamber the company will be enabled to light an area comprising Cornhill, part of Bishopsgate-street Within, Threadneedle-street, part of Old Broad-street, Throgmorton-street, and the lesser thoroughfares leading between these streets. For the purpose of lighting this area 7,000 incandescent lights have already been applied for, including 1,200 lamps by the Bank of England. To light this area it is necessary that the company should have a transformer chamber within 50 yards, at least, of St. Benet Fink churchyard. The Commissioners of Sewers have granted permission for the erection of these chambers in narrow thoroughfares, but have refused permission in the present case, as its construction would disarrange the telephone and telegraph and gas and water companies' pipes; and owing to the site required being a crowded thoroughfare, it would be for other reasons objectionable. The company has also approached owners of adjoining property with a view to arrange for a sale of the site required without success. They have no compulsory powers to compel a sale of land for the purpose under their Act; and in the result, if this application were to fail, the area in question will remain unlighted by electric light. The petitioners have thus made out a strong case of urgency in the interests of the parishioners and public in favour of their application. It also appears that several applications have been made to the company to light the City churches for Sunday evening services, which are well attended, and it is therefore against the interests of the Church that the scheme should fail. The company also offer the payment of £25 to be appropriated towards the church expenses of the parish church. The special facts in support of the application in the case of St. Nicholas Cole Abbey are as follows: The church and churchyard abut on Queen Victoria-street. Part of the churchyard was many years ago appropriated, under an Act of Parliament, for the construction of the District Railway. The chamber required cannot be constructed under the streets owing to there being a subway for the supply pipes of the water and gas companies, and the company have failed to acquire a site by private purchase. The proposed chamber will supply from 20,000 to 25,000 incandescent lamps, and there have already been applications for 5,000 lamps. The church is lighted with electric light, and the company offer an annual payment of £30 towards the church services. If the faculty is refused the electric lighting of the church will cease. The area to be lighted from this chamber will be the whole of Queen Victoria-street as far east as Cannon street, a great portion of Upper Thames street, Knightrider street, and the lesser intervening thoroughfares. The refusal to grant the faculties asked for will deprive the streets and houses and offices in the areas mentioned of the advantage of being lighted by electric light, and the question before the Court is whether it has a discretionary jurisdiction in the matter, and if it has whether it would be proper exercise of it to grant the faculties prayed. It has already granted two faculties to this company, giving it the use for 21 years of portions of two churchyards in the City for the construction of an entrance and subway to transformer chambers, constructed by permission of the Commissioners of Sewers under narrow streets. This case does not come within the class of cases referred to in "The Queen against Twiss" (L.R. 4, Q.B. Cases, 407). The rule applicable to this and kindred cases is thus laid down by Sir John Nicholl: "Faculties are to be granted at the discretion of the Ordinary, but it must be a sound discretion, having a due regard to times and circumstances, and to the rights and interests of all parties concerned; if an unsound discretion be exercised a party may appeal to a superior tribunal" ("Butt v. Jones," 2 Hagg's Eccl. Reps., 424). The Court is of opinion that it would not be exceeding its jurisdiction in granting the faculties prayed, and that under the exceptional circumstances of these two cases it will be exercising a sound discretion in granting them. It therefore decrees the faculties as prayed—the faculties not to issue within 15 days, and advertisements to be inserted in the *Times* and *City Press*. So as to enable any members of families buried in the vaults to make application to me in chambers relating to their removal, a proviso will be inserted in the faculty permitting the removal of remains if desired, by members of the families to any consecrated burial ground selected by them. The other remains will be removed to the parochial burial grounds of the respective parishes for reinterment in the consecrated portion of the cemetery.

Mr. Arnold Statham appeared for the petitioners.

COMPANIES' MEETINGS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY.

The second annual general meeting of this Company was held at Winchester House, Old Broad street, E.C., on Thursday, the 1st inst., Sir David Salomons, Bart., chairman of the Company, presiding.

The **Chairman** said that on the last occasion he had the honour of appearing before them it was with considerable difficulty that they succeeded in getting the one shareholder to attend who constituted their audience. It was gratifying, therefore, to find there was a good attendance of shareholders. It showed that, if before they had complete confidence in their Board to carry out the affairs of the Company, their interest had been awakened; but he trusted that their confidence was not lessened in consequence. Before moving the adoption of the report he proposed giving them a full account of the work they had done since the last time he addressed them. Application was made for shares amounting to £300,000, which they considered very good, having regard to the fact that the times were bad. At the period he spoke of £100,000 worth of shares remained to be applied for, but the amount had since been taken up, he was glad to say, and the money would be employed at their works in a very short time. It was therefore the intention of the Board to

issue preference stock to the amount of £200,000 at 6 per cent., and to give the shareholders the first chance of obtaining it. That 6 per cent. was very well secured, and it might be regarded as a first class property when in their hands. Before very long—he did not mean in a month, or even six months, but perhaps in 12 months—he did not want to be too hopeful—they would be able to pay a dividend to the ordinary shareholders. Matters were now beginning to mend. The first difficulties which had to be encountered had been met, and their affairs were beginning to take a turn. Their stations were working at a small profit, which would grow as the machinery came more and more into work. They were not working at full load, but as time went on the profits would increase. At the present time their sites and buildings and other works—in fact, a great many matters which he would not trouble them with, but which must exist—brought in no return. That was a necessity with undertakings of that nature. All the money they were now expending would be fruitful. There were one or two points in the report he would like to call attention to. They stated that "from calculations based on the lamps already connected to the Company's mains, it appeared that the consumption of current per lamp installed in City offices, shops, etc., would be much greater than was anticipated." It had been pointed out to him that that might be taken to mean that the consumers of electric energy in the City were in some way at a disadvantage. But that was not so. In the West-end, where there were drawing rooms and occasional parties and shops which were only lighted for a short period, the number of lamps installed was four times more than those in general use. In the City all the lamps would be in use when the weather was dark, and consequently the return would be far greater. It did not mean that the customers in the City would be at a disadvantage, but that the circumstances were favourable to the Company. Sir David then dwelt on the importance of not stinting money in putting up the fittings. Nothing had brought a bad name to electric lighting in the City so much as cheap fittings. With water, gas, and sanitation they were most particular. Why should they not be so with the electric light? The whole of the evil was generally attributable to the lowest tender for the work being accepted, instead of taking the offer of the firm that would execute the requirements in the most satisfactory manner. All the work executed by the Company in erecting their fittings was extremely well done. There was no bad work of any kind anywhere. They wanted to make the concern an example to London and all the other great cities of the world. There would be no hurry, and the Company were not going to allow a bad name to be brought on to the City. No trouble was being spared by the Board, who gave every attention to the details in connection with the affair. They had the experience of other companies of a similar nature, and the shareholders were having the benefit of that knowledge. There was only one matter for regret he had to mention. One of the directors, the Hon. Alan Charteris, who had taken a most intelligent interest in all they had been doing, became suddenly ill, and he had been away for some time. It was gratifying to know that he had returned from abroad very much better, and they all hoped very soon to find him at the Board meetings once more. In the accounts the sum of £1,500 appeared as being due for calls, but that had nearly all been paid since the balance sheet was printed. The accounts as printed did not convey very much information, but that could not be helped during the progress of the work. They hoped to send the shareholders a much fuller statement presently. In the West end there would be a considerable amount of current used between the hours of 4 p.m. and 9 p.m., but at other times the demand would be small. The light in the City would be very different. The amount of current required would be far more constant, and this, of course, was a very good thing for the shareholders, because they would be making a great deal more out of the machinery, which they would be bound to keep running. What they were longing for was a good London fog. They had some experience last week of a dark day in London, which frightened them a little, but the trouble would never occur again. They wanted some good fogs—favourable dark days—and then they would be able to discover what the City population really required of them. The Board had always endeavoured to supply the current as cheap as possible, and if they were able to reduce it they would be glad to give the consumer the benefit of it. He could not speak too highly of the work done by their officers, who had been pushing matters forward as much as possible consistent with reason. A little patience would have to be exercised on the part of the public, and in a few months they would be able to give entire satisfaction to the citizens. They had laid under the ground much more plant than would be required, but in spite of that fact his private opinion was that the demand for the light would grow so rapidly that they would have to have the City up again and lay more mains. But that would not happen for five years. The crane, pumps, and other machinery at the stations were to be worked by electric motive power because it was convenient and cheap, and the public would then be able to see that the system was an economical one. They hoped that railway stations and other public places would soon be lighted by their light when the Board of Trade regulations were less severe. By the spring of next year it was expected that their stations would be able to supply 78,000 8 c.p. incandescent lamps, in addition to the 700 lamps in use now. Their gross earnings were now £20,000, and every increase of light meant a considerable measure of profit. In order that they should not be taken unawares when the dark days came, they intended making an experiment. They proposed to take observations from high places to see if fogs were coming. The Docks Committee had kindly promised to telegraph any information of fogs coming up the river, and other bodies would communicate with them as far as possible. If they only had 10 minutes' notice of the coming of the fog they would be all right; and if the fog came from above without any intimation—well, then they would give it their best attention while it was here. As regarded street work, as much as 30 miles of tubing had been placed underground in a week, but the average was 10 miles a week. The contracts with the Corporation for arc lighting the main thoroughfares would be complete in two or three weeks. In addition to that they had put up many lights which were not compulsory. Their last day for completion was November 5, but they had finished two months before the stipulated period. The shareholders would, he thought, agree with him that they had in no way been asleep. He then moved the adoption of the report and balance sheet.

Mr. A. Pursell, C.C., seconded the proposition, which was agreed to without discussion.

Messrs. W. H. Pannell and Co. were re-elected auditors of the Company at the remuneration of 100 guineas.

Mr. Copland proposed a vote of confidence in the Board, remarking that the shareholders were very much indebted to them.

Mr. E. M. Smart seconded, and the resolution was adopted *nem. con.*

The **Chairman** thanked the shareholders for the compliment, and hoped the result of the Directors' work next year would be satisfactory to the proprietors.

The proceedings then terminated.

BUSINESS NOTES.

Chertsey.—Advertisements are to be issued for offers to light the district electrically.

Great Northern Telegraph Company.—The receipts for the month of August were £23,600.

Railway Stores.—Messrs. Angus and Co., of Liverpool, are inviting tenders for 20 tons of galvanised telegraph wire.

West India and Panama Telegraph Company.—The receipts for the half month ended August 31 were £1,930, against £2,428.

Bristol.—Sanction has been given by the Local Government Board for the borrowing of £66,000 for electrically lighting the town.

Eastern Telegraph Company.—The receipts for the month of August were £49,069, as against £53,398 for the corresponding period.

Cuba Submarine Telegraph Company, Limited.—The receipts for the month of August were £11 less than for the corresponding period.

Loughborough.—Plans for the extension of factory and stores for the Brush Electrical Engineering Company have been approved by the Town Council.

Derby.—Tenders are invited for electric lighting machinery and accessories at the central station. Full particulars will be found in our advertisement columns.

Dolgelly.—The Dolgelly Local Board have decided to light the town with electricity. Mr. Hall, of Liverpool, has contracted to light the town during the winter.

Pitlochry.—Messrs. A. and J. Macnaughton, manufacturers, have just completed the successful installation of electric light in their Pitlochry tweed mills and warehouses.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £3,166.

Hertford.—Enquiries as to the question of the electric lighting of Hertford are being made, and the local authorities have issued a pamphlet upon the subject detailing the advantages.

Northern Electric Wire Company.—The Northern Electric Wire and Cable Manufacturing Company, Limited, Halifax, have again declared their interim dividend at the usual rate of 7½ per cent. per annum.

Dublin.—Application has been made by the municipal authorities for a loan of between £1,500 and £1,900 for the supply of electric light fittings to the Corporation offices and the fire brigade stations.

Blackburn.—A deputation from the Town Council has been in consultation with the Local Board to consider the question of the purchase by the Corporation of certain land belonging to the Board for the purpose of erecting an electric lighting station.

Barnet.—Some members of the Barnet Local Board have been engaged in obtaining further information about electric lighting, and a special committee will, we understand, report to the Local Board recommending an application for a provisional order.

Conservative Club.—The contract for the wiring of the Conservative Club, St. James's-street, which work, as mentioned last week, is being carried out under the superintendence of Mr. A. A. C. Swinton, has been placed with Messrs. Hancock and Rixon.

Glasgow.—The Corporation Tramways Committee invite persons desirous of submitting estimates to equip certain of their tramway routes for working on the overhead wire system, to communicate with their general manager, Mr. John Young, City Chambers, Glasgow.

City and South London Railway Company.—The receipts for the week ending September 4 were £737, against £672 for the same period of last year, or an increase of £65. The total receipts for 1892 show a total increase of £621 over those for the corresponding period of 1891.

Sunbeam Lamp Company.—This Company notify that although they have temporarily ceased the manufacture of the Sunbeam lamp, they are still supplying their patent Sunbeam holder, and the Edison Swan Company, to meet the demand, are making lamps to suit these holders.

Light and Power at Tornavento.—The water company intends to erect a light and power station for the distribution of energy in the districts of Busto, Legano, Gallarata, and Milan. It is intended to erect a plant sufficient to distribute 25,000 h.p., about half of which is required for the district of Milan.

Hanley.—We understand that the tender of the Brush Company, amounting to £15,760, has been accepted for the electric lighting at Hanley, and sanction is to be obtained for the borrowing of £15,760 for this purpose and also for £5,240 for buildings, etc., the amount so borrowed to be repaid within 60 years.

Telephony.—It has been resolved to connect Glasgow and Belfast *vid* Stranraer. Operations have been commenced simultaneously at Glasgow and Stranraer with the formation of a trunk wire and the cable will be laid in the spring. It is intended to tap the wire at several places between Glasgow and Stranraer.

Heckmondwike.—A meeting of the ratepayers was convened to consider the question of the proposed electric lighting of Heckmondwike, but owing to the inclemency of the weather and other causes the attendance was very small. It was suggested that the meeting should be postponed to another evening. The suggestion was adopted.

Chelmsford.—The report of the Lighting Committee to the Council gave an account of an interview had with a representative of Messrs. Crompton and Co., Limited, as to the irregularity in the electric lighting of the town. Messrs. Crompton and Co. wrote hoping that the new arc lamps would be fixed in seven weeks' time. They were making every effort to get the work through.

Chatham.—Proposals, it is stated, are now being made that the Chatham Corporation should purchase the electric light undertaking, which is at present in the hands of a company. At Maidstone the provisional order has been retained by the Corporation, by whom the powers will probably be utilised. Canterbury and Dover, on the other hand, have practically come to terms with the Brush Company, and early installations may be expected in both towns.

Rome.—Those who rave about the antique are dissatisfied with the lighting of Rome by electricity. It is a great pity that some of these people could not be relegated into the mediæval times, or, better still, be compelled to live in some part of the earth where they could retain their peculiarities of civilised life of a thousand years ago. Why should a city like Rome be deprived of the advantages of light because a few thickheaded individuals like to see it as it was in the days of the Cæsars?

Bray.—The electric lighting of Bray will be finally completed in the course of a few days. The contractors, Messrs. J. E. H. Gordon and Co., 11, Pall-mall, London, have been running the plant for some time, but the Commissioners' contract will not commence until, as stipulated, the water power is supplemented by steam plant for times of extreme drought or frost. The engines are now almost complete, and Messrs. Gordon expect to commence running under contract by the end of this week or early next.

Companies of the Month.—The following electrical companies have been registered during the past month:

Colner Marr Telephone and Electrical Manufacturing Company, Limited, £10 shares	£100,000
Hove Electric Lighting Company, Limited, £5 shares	40,000
Kennedy Storage Battery Company, Limited, £1 shares	100,000
United Electric Sewage and Chemical Syndicate, Limited, £1 shares	5,000

Derby.—The Town Council has bought several houses and a piece of land for the purpose of enlarging and improving the new electric lighting station when occasion requires. The Electric Lighting Committee have accepted the tender of Messrs. G. Fletcher and Co., Derby, for boilers and accessories at the electric light station, and the building and dynamo contracts are in preparation. The committee recommend the appointment of a resident electrical engineer to act as clerk of the works during their construction, and to manage them when completed.

Weybridge.—Three months since the authorities granted the promoters of the electric light at Weybridge an extension of three months in order that they might be able to raise capital and satisfy the requirements of the Board of Trade. This three months has expired, and the company has practically done little or nothing towards the matter. A meeting has been called in Weybridge, and a small committee appointed. If the necessary capital cannot be raised locally, a syndicate will probably take the matter up, so under the circumstances, the Authority has granted a further extension of three months.

Whitehaven.—At a meeting of the Electric Lighting Committee of the Whitehaven Town and Harbour Trustees, tenders for iron and steel work for foundations of engines and dynamos to be placed in the sewerage engine house for the purpose of electric lighting were considered, and it was recommended that the tender of Messrs. Ramsay Bros. being the lowest, be accepted by the Trustees. It was also recommended that the tender of Messrs. Galloway, Limited, of Manchester, for two boilers be accepted, and the tender of the International Okonite Company, Manchester, for conductors be also accepted. The acceptance of these tenders is subject to the sanction of the Local Government Board being obtained to the loan for electric lighting purposes, which has been applied for.

Burnley.—The Local Government Board has sanctioned the application made by the Council for permission to borrow £23,500 for the purposes of the electric lighting of the borough. The Electric Lighting Sub-Committee also accepted the following tenders in connection with the work required in the erection of the electric lighting station in Grimshaw street, on the site of the old Pillingfield Mill: T. Smith, Burnley, excavating, masonry, and bricklayers' work, £2,764 11s.; E. Wood, Manchester, ironwork, £423; R. Dean and Sons, Burnley, carpentering and joinering, £550; Owen and Co., Burnley, plumbing and glazing, £259; Whittaker and Schofield, Burnley, slating, £128; T. S. Ratcliffe, Burnley, plastering and painting, £103 7s. 8d. At a meeting of the Fire Brigade Sub-Committee the tender of Mr. John Barritt was accepted for the fitting up of a series of electric fire alarms from the central fire station to the houses of the firemen.

Llanelly.—In connection with the proposed lighting of certain streets in the town by electric light, the Local Board, at Monday's meeting, considered a report of the committee of the whole Board upon the subject of the offer of the British Electric Installation Company, Limited, to take over the provisional order and cost of the same, the Board to have power to purchase the undertaking at any time within 42 years, either by capitalising the net profits or paying the actual capital expended, as shown by the books of the company, the purchase money to be paid in bonds or stock of the Board, bearing interest at 5 per cent., redeemable at par at the end of 21 years. In the event of the company having a dividend of 10 per cent. upon the capital, the price charged to consumers of electricity to be reduced a ½d. per unit for every complete 10 per cent. paid over and above 10 per cent. Clause 52 of the order to be excepted from the transfer, the Board also to have the power to excavate the trenches for laying the mains, the company paying the cost thereof.

Hayle.—On Saturday evening last the electric light was inaugurated for the first time in Copperhouse on the premises occupied by Messrs. J. and F. Pool, metal perforators and ironmongers. The contract for the installation was secured by Mr. F. M. Newton, of Taunton, and the work has been most successfully carried out by his representative, Mr. Edgar Pool. The light was switched on by Miss W. Pool, the whole of the establishment being immediately illuminated, the contrast between the old and new light being very marked. The motive power used for driving the Taunton dynamo is supplied by the engine which drives the perforating machinery. The dynamo is capable of supplying 36 16-c.p. lamps, all of which can be controlled from the engine room by means of a switchboard, upon which are also the instruments to indicate the voltage and the number of amperes generated. Each lamp has also a separate switch, so that any number can be turned off at pleasure. During the evening an electric search light was displayed from the rear of the premises by Mr. Pool.

Australia.—The Rockhampton Gas and Coke Company's report just to hand says: "Since the last meeting the work of installing the electric light has been proceeded with. The bulk of the plant has already arrived, and is in course of erection. Special care has been exercised in procuring the best and most improved description of dynamos, engines, boilers, and other important machinery, and the directors are assured by the electrical engineer, upon whom they have to depend for advice in all matters appertaining to the installation, that the light will be satisfactory and reliable in every respect. It is expected that the electric current will be in operation by the end of August. The general offices and showroom are now located in the new buildings in Alma street, and have already been of great service to the company's constituents. As you are aware, debentures to the value of £10,000 were issued about two years ago in anticipation of the capital required for the electric light installation. It was afterwards considered advisable to devote part of this for the erection of a new gasholder, which reduced the amount by over £2,000; other enlargements in the gas plant, notably the extension of the mains to North Rockhampton and the hospital, have also encroached on the amount originally in hand, and it will, therefore, be necessary to issue more debentures or shares to keep pace with the further developments that will take place with both the gas and electric light. All the projected extensions promise a very good return upon the capital involved."

Aberdeen.—The Town Council of Aberdeen at their last meeting discussed the recommendation of the Gas Committee that the Corporation should proceed with the lighting of the eastern district of the city at an estimated expense of £24,000. Prof. Kennedy, London, who had been consulted, reported that the compulsory area should include Castle street, Union street, as far west as Bon Accord street, Market street, Broad street, St. Nicholas street, the southernmost block of George street, Schoolhill, and the circuit round the new road by the Free Library, and down Union terrace. About 10,000 lamps of 8 c.p. would be installed, of which about 7,000 would be in the eastern and 3,000 in the western district. The central station will be located in Cotton street. If 8d. per unit were charged at starting (this being 1d. below the maximum), Prof. Kennedy considered that the Council might fairly hope to earn an income at the rate of at least 9s. per annum per lamp installed, or £4,500 by the time they had the equivalent of 10,000 lamps on circuit. Mr. Bisset moved, and Mr. Johnston seconded, that the scheme be proceeded

with. Bailie Nicol moved as an amendment that steps should first be taken for the purpose of ascertaining the probable number of consumers in the district proposed to be lighted, and this was seconded by Mr. Farquharson. On a division it was resolved by twenty-four to five to proceed with the lighting of the eastern district as indicated in the report, and it was remitted to the Gas Committee to have the scheme carried into effect.

Morecambe. – A deputation from the Tradesmen's Association from Fleetwood went the other day to inspect the electric light at Morecambe. Messrs. S. Fletcher and J. Smyth. Mr. Richard Edmonson, of London, of Fleetwood pier fame, was also on board, as well as Messrs. T. Clark, R. Carter, and Lowthwaite, who accompanied the representatives of the Tradesmen's Association to the central lighting station, where they were shown round by Mr. Collinson, the superintendent. They learned that there was plant at Morecambe equal to 1,000 lamps (8 c.p.). The cost of the plant was £4,500, and they have more applications for the light than they can supply, at least until they increase their power. Upon making further enquiries they gleaned from Mr. Cutts, chemist, who had nine 8 c.p. lamps in his establishment, that the electric light cost him £4. 10s. per annum, and his gas bill previously ran from £10 to £12 per year. At the next shop, the proprietor also said the electric light was undoubtedly cheaper than gas, and advised them by all means to urge its adoption at Fleetwood. Mr. Birkett, chemist, said he had eight 8 c.p. lamps, for which he paid £3. 12s. per annum. He had contracted for the light for three years, and thereby got a reduction. He was also allowed 5 per cent. off the above price. With the same number of gas lights his bill was from £4 to £5 per year. At the central station the deputation also inspected the accumulators, which are used for storing during the day the power required at night. The effect is to keep up a steady current. The supply cannot be shut off in a moment, and if the engine stops the accumulation is there. We believe a very favourable report will be presented to the Tradesmen's Association regarding the electric light.

Cork. – The Cork Gas Consumers' Company has given notice to the Corporation that it intends to apply for a provisional order to supply electric energy within the municipal borough. At the last meeting of the Corporation a deputation from the gas company, consisting of Mr. Geo. Lynch (chairman), and Mr. Denny Lane (secretary), attended the meeting in support of the application. Mr. Lynch pointed out that although not absolutely necessary to obtain the consent of the Corporation, it would facilitate matters by so doing, and the gas company being entirely composed of fellow citizens, they had no wish to have any contention with the Corporation. If the Council thought the time had come when the city should have the advantage of the electric light, the gas company could certainly supply it on better terms, and on more advantageous terms, than any electric light company, who would have to depend for profit solely upon the electric light. They could supply the Corporation on better terms. Some persons had got the idea that if the gas company got the electric lighting into their hands they would starve it for the benefit of the gas business: he promised that this would not be so. The gas company had no power at present to apply any portion of their funds for electric lighting. If the electric light was introduced, the city would be better lighted than it was at present. Mr. Lynch pointed out that it was not well lighted now, owing to the class of burners the Corporation had placed on the lamps. Of course, the expenditure would be increased. Mr. Lane, after some conversation between the chairman of the Corporation and others, pointed out that the gas company would be in a position to supply at a much cheaper rate than any other company, and described in detail the manner in which the light would be supplied throughout the city for household and municipal consumption. He thought the electric light could be supplied in the first instance at 8d. per unit, and the price diminished as the consumption increased. An amendment to the acceptance of the gas company's proposition was made by Mr. Julian, who wanted the matter sent back to the Electric Lighting Committee to be considered with the increased information now before them. Sir John Harley Scott seconded this amendment, and when put to the vote the result was an equality of votes for and against. The chairman would not give a casting vote, so that the amendment fell through. Mr. Alderman Dale proposed as a further amendment that the consideration of the gas company's application should be postponed until they had a report from the committee, and this suggestion was adopted.

PROVISIONAL PATENTS, 1892.

AUGUST 29.

15469. **Improvements in signalling apparatus for telephones.** Georg Eduard Heyl, 4, Little Moorfields, London. (Complete specification.)

15477. **Improvements in the means for and method of melting metals and other materials by electricity.** August Friedrich Wilhelm Kreinsen, 70, Market-street, Manchester. (Complete specification.)

15492. **Improvements relating to the lubrication of parts of machinery with the aid of electricity.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (Johann Friedrich August Hoppe and Albert Jacobsen, Germany.)

15501. **Improvements in means for lighting oil lamps by electricity.** Joseph Domecq Cazaux, 4, South-street, Finsbury, London. (Complete specification.)

AUGUST 30.

15552. **Improvements in and relating to electric cigar-lighting lamps.** William Joseph Eastman, 77, Chancery lane, London. (Complete specification.)

15591. **Improvements in electric arc lamps.** Johann Christian Wüst, Norfolk House, Norfolk-street, Strand, London.

AUGUST 31.

15649. **Apparatus for continuous decomposition of alkaline chlorides by electrolytic fusion.** Jean Stoeck, 28, Southampton buildings, Chancery lane, London.

15650. **Electric apparatus for illuminating the sights of fire arms at night.** Giovanni Garassino di Giovanni, 28, Southampton buildings, Chancery-lane, London.

SEPTEMBER 1.

15665. **A method of eliminating the cross-magnetism in the armatures of continuous current dynamo electric generators and motors.** James Dick and William Scott, Greenhead, Glasgow.

15671. **Medicated electricity or special use and application of electricity for medical purposes.** David Balmford, 20, St. Andrew's place, Bradford.

15689. **Improvements in relays for electric telegraphs.** Cyprien Renelde Joseph Willot, 47, Lincoln's inn fields, London.

15690. **Improvements in overhead trolley for electric railways.** Benjamin Kochs and Albert Kochs, 52, Chancery lane, London. (Complete specification.)

15691. **Improvements in electric air ships.** Charles Drill, 52, Chancery-lane, London. (Complete specification.)

SEPTEMBER 2.

15767. **Improvements in gas outlet valves, or plugs for electric battery cells or other like vessels.** William Mosetop, 47, Lincoln's inn fields, London.

15790. **An electric lantern.** Henry Charles Gover, 28, Southampton buildings, Chancery lane, London.

15793. **Method of smelting or overheating iron or other metals by mean of electricity.** Carl Gustaf Patrik de Laval, 77, Chancery lane, London. (Date applied for under Patents Act, 1883, Sec. 103, March 8, 1892, being date of application in Sweden.)

15795. **An improved system of electrical distribution.** Sydney Ferris Walker, 45, Southampton buildings, Chancery lane, London.

15799. **An improvement in galvanic batteries.** Edward Nunan and John William Nelson, 160, Fleet street, London. (Complete specification.)

SEPTEMBER 3.

15813. **Improvements in the formation of junctions for electric mains.** Arthur Moor Thompson, Holly Bank, Crewe.

15833. **Improvements in telegraphic apparatus.** William Phillips Thompson, 6, Lord street, Liverpool. (Louis Dill, Germany.) (Complete specification.)

15840. **Improvements in electric arc lamps.** Rookes Evelyn Bell Crompton and Edmund Arthur Norman Pochin, 55, Chancery lane, London.

15864. **Improvements in electrical switches.** Claude William Atkinson, 1, Queen Victoria street, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1891.

11712. **Electric batteries.** Hall.

16250. **Dynamo machines.** Hammond and Hall.

16293. **Electrically propelling ships, etc.** Heys. (Heilmann and another.)

18179. **Dynamo-electric machines.** Gay and Hammond.

13125. **Carbon holders, etc., for electric welding.** Howard. (Second edition.)

1892.

8875. **Electric motors.** Cooper.

12745. **Electric signalling.** Allison. (Standard Electric Signal Company.)

NOTES.

Pilsen.—The municipality has obtained the consent of the State for the construction and working of an electric tramway, and the scheme already prepared will be carried out.

Rosario.—Calle San Martin, Rosario, has been lighted by electricity, and, in consequence of the dispute with the gas company, it is believed that its use will be extended to other streets.

Birmingham.—The "Looker-on," in the *Birmingham Post*, suggests that it is about time "the Corporation followed the example of the British Museum and other important libraries and adopted the electric light."

Kimberley Exhibition.—A short time ago, visiting the works of Messrs. Mather and Platt, we inspected the electric lighting apparatus which was designed for the Kimberley Exhibition. We understand that the plant is working admirably.

Temesvar.—Negotiations are said to be in progress between the Brush Electrical Engineering Company, the owners of the central station at this town, and the municipality, with a view to the latter purchasing the station. The price asked by the company is 222,000 florins.

Aix-les-Bains.—This well-known pleasure and health resort has been provided with an electric lighting station. The local gas company propose to work the station, but it is said that the municipality have received offers from private individuals to supply electric light 30 per cent. cheaper than the gas company.

Electric Traction in Brussels.—Some time ago the Thomson-Houston Company made certain proposals to local railway companies with a view to the adoption of electric traction on their lines. These offers have been accepted, and the local authorities have given their consent to the construction of three or four new electric tramways.

The Popp System.—It is rumoured that differences have arisen between M. Victor Popp and a number of important shareholders in his company who are German bankers. It is said that the latter wish to interfere with the affairs of the company and put M. Popp in the background. The latter, it is stated, will resign rather than tolerate any interference.

Electric Lighting of Trains.—The Western and Eastern French railways have made experiments in the electric lighting of some of their trains, and although the results were not conclusive, they were yet encouraging. The tests were made with the Meritens battery, which is a modification of the Smée battery. It is proposed to make further tests during the coming winter.

A Miniature Church Installation.—Probably the smallest electric light installation in the world is to be found in the little village of Bremen, near Dermbach, in Thuringia. It comprises a single arc lamp installed in the church, the lamp being energised when required by a small dynamo arranged in the village mill, and driven by the mill wheel by the power of the mill brook.

A Little Mistake.—A lady in the Palace Hotel, San Francisco, requested the clerk to call a messenger boy. Not receiving a prompt answer, she concluded to "press the button" herself. The "button" she happened to select proved to be the electric light switch, and when she operated it the whole first floor of the hotel was thrown into darkness. When light was restored, the lady had vanished.

A New Current Regulator.—Mr. Gustav Cons, of Hamburg, has devised a maximum-current regulator. Its object is to prevent an increase of current over a certain maximum pressure—not as an ordinary lead fuse which completely breaks the circuit, but it renders possible the further passage of the current by the insertion of a resistance. It is proposed to use this device with batteries of accumulators, and in place of electricity meters in house installations.

Cassel.—A report has been published concerning the working of the central station at Cassel, which was started in July of last year. The report is brought down to the end of March last, when there were 180 arc lamps and 2,609 incandescent lamps connected to the mains. This number has since been considerably increased, and electricity is about to be adopted as the motive power in some large works.

Lightning Conductors.—The German fire insurance companies have commenced a scheme to compel policy holders in country districts to erect lightning conductors on the buildings insured. One company proposes that at least two conductors should be erected on each building, the cost to be equally divided. Another company is offering reductions of from 5 to 10 per cent. in the premium to those owners having lightning conductors on their property.

Glasgow.—Some time ago the *Glasgow Herald*—if we remember rightly—gave an excellent series of articles upon the tramways question, and it seems to have commenced another similar series at the present time. In the first of these articles the question of the use of accumulators is discussed, and the conclusion arrived at is that so far accumulator traction has not been a success. In the second, statistics and comments are given on cable traction. The information is up to date.

Dundee.—The men engaged in Tally-street preparing for the electric light, in their digging this week have come across some human bones and also parts of skulls. The vicinity of the East Church favours the idea that in the long past a churchyard must have been located here. It is surprising how many of these relics of the dead are turned up in Dundee streets when for any purpose these have to be opened. Much of the ground throughout the centre of the town seem to have been places of burial.

Newcastle.—It is gratifying to see that the tradesmen are beginning to take an interest in the lighting of the streets, and have induced the Town Council to put up an electric lamp at the junction of Newgate-street and St. Andrew's-street. It has been a difficult job to move the Council to act, for we understand that Mr. Aves and the Newgate councillors' ward have been endeavouring to obtain this boon for the last 18 months. We are glad to find that they have achieved their object in the end.

Hanley.—We are glad to see that the local people are supporting the action of the Corporation in undertaking the work of supplying the electric light. In a few years it is absolutely certain great credit will be given to those who had the foresight to undertake this work themselves, and who had sufficient stamina to laugh at the ever-ready cry of those who would wait till doomsday before taking action. All people who consider the question unbiassedly must see that the properties of electric lighting are so much and so many in advance of those of any other artificial illuminant, that in the long run it is bound to become commonly used.

The Budapest Electric Railway.—According to a report for 1891, the traffic on this well-known electric railway considerably increased during that year. The

length of the line increased from 9·1 kilometres at the end of 1890 to 11 kilometres in 1891, and since then the line has been again extended. The greater portion is double track, and 62 cars are in service. The plant at the generating station has been augmented to 700 h.p. In 1890 758,838 car kilometres were run, and in 1891, 1,489,409 car kilometres. The number of passengers carried in 1890 was 4,459,234, and in 1891, 8,619,215 persons were transported, the receipts being almost double.

Signalling.—Experiments have recently been made from the summit of Mount Washington by means of a search-light, under certain conditions of the sky, by throwing the light upwards at an angle of about 45deg. The reflection was seen about 85 miles. Telegraphic messages by means of flashes were sent from Mount Washington to the Western Union offices in Portland, and answers returned by wire. It is said that this visual signalling by electricity is better by sunlight. We beg leave to doubt it, inasmuch as everyone who could witness the effect of the light upon the cloud could be able to read the intelligence which was being transmitted.

Bowness.—The lighting question has progressed a step further. The proposition is to utilise the water power at Troutbeck Bridge, and the company propose to distribute the light throughout the districts of Bowness and Windermere, the main cable being laid from Bridge Mill to Windermere Station and on to Bowness. At the Board meeting Mr. Fowkes explained all the proposals, and stated that it was not contemplated at first—if the company could obtain the leave from the local authorities—to obtain a provisional order, but the clerk to the Board suggested that it would be advisable to have a provisional order, as the cost would be trifling provided there was no opposition from the two Boards interested in the matter.

Taunton.—The correspondence with regard to the proposed electric light station still continues in the local papers. We have now the astonishing information from Mr Standfast that he estimates the first year's loss at nearly £7,000, but it is difficult to imagine how any sane man can obtain the amount as he does. He puts down as loss, among other things, the procuring of a license £350, and then the procuring of a provisional order £150. We do not quite see that they require both a provisional order and license. Then the paying off of the principal he puts down as loss. Anyone who can give figures of this character must be very hard up for legitimate criticism, and anyone who can accept figures of this kind must be ready to swallow a whale, no matter how large it may be, with his eyes shut.

Rubbish.—A Colonel Henkle proposes to construct a house across the brink of Niagara Falls, and so utilise the power of the falls to drive electric generators, transmitting the power obtained to long distances. Our contemporary *Electricity* suggests that Colonel Henkle should himself be exhibited at the World's Fair, and that he should be allotted ample space. We quite agree with this. Unfortunately, idiotic suggestions of this kind made from time to time, not only in America but in England and on the Continent, are duly telegraphed to our ordinary newspapers and generally meet with the honour of big type. It may be that Colonel Henkle will try to get money on this side for the purpose of investigation. If he does and gets it, the result will be another proof of the old adage—viz., "Fools and their money are soon parted."

Lighting in Spain.—A correspondent of the *Elektrotechnische Zeitschrift* in Spain states that the firm of Planas, Flaquer, and Co., of Gerona, is the only concern in that country which builds dynamos. The company was started in 1857 as an iron foundry and engineering works, and in 1887 an electrical department was added. The lack of coal causes small towns and even villages either to adopt oil or the electric light as an illuminant, gas offering but little competition throughout the greatest portion of the country to the electric light. Water power is used at the Gerona central station, and both alternating (Ganz) and continuous current machines. The same writer concludes that German firms, and it may also be said English as well, who wish to do business in Spain will have to meet the keen competition of the Spanish works, as the Spaniards believe in protecting native industries.

Leeds.—We may add the following information to the note we had in our last issue on this subject. We then said that the company hoped to commence laying the mains in the thoroughfares which it is proposed to light as a commencement. These streets, as our readers are aware, include practically all the area bounded by Wellington-street, Boar-lane, Briggate, Upperhead-row, Woodhouse-lane, Cookridge-street, Park-lane, East-parade, and King-street, and also certain streets beyond this boundary, such as Kirkgate, New Briggate, St. Paul's-street, etc., as well as the entire distance to the Oak Inn, Headingley. The erection of the works in Whitehall-road is progressing rapidly, and the construction of the plant is also in an advanced stage, some of it indeed being already in its place at the works. There seems to be no reason to doubt that the company will, in accordance with their previously expressed opinion, be in position to supply electricity in November.

Electric Traction in Paris.—It is intended to work two tramways in Paris by electricity as soon as the authorisation has been given. The first will start from the Place de la Madeleine, and will terminate at the Saint-Denis (Place au Gueldres), and will be slightly over five miles long. The second line will start in Paris at Rue Taitbout, and will finish at the other end of Saint-Denis, at La Patte D'Oie, and will be nearly six miles long. The cars are of the storage battery type, and 16 will be placed on the two lines. Each car is fitted with two motors of the Manchester type, and the reduction in speed is effected by two sets of gearing. The cars each carry 52 passengers, and the accumulators are contained in six boxes placed under the longitudinal seats. The accumulators have been made by the Société pour le Travail Electrique des Meteaux. The depot will contain four steam engines of 125 h.p. each, running at from 70 to 160 revolutions a minute. These engines will drive Desroziers dynamos, each giving 60 kilowatts. The experiment with these 16 cars will be made by the Northern Tramway Company.

Speed of Electric Launches.—Referring to the notice of the "Electra" for Chicago Exhibition, Mr Magnus Volk writes about the company's claims that, "It is a pity such wild statements are made as to the speed of electric boats. I have fitted up about 15 electric launches from 28ft. to 75ft. long, and I much doubt if in still water (the only true test) it is possible by any means to get an electric launch, under 50ft. long on water-line, to make 12 miles an hour in still water. I have a great many diagrams of speed and electrical horse-power absorbed, and in spite of glib statements of small boats running eight and nine miles an hour, I find that seven miles an hour is about the most to be got out of electric launches, and with the cells in two parallels 4½ to 4¾ miles an hour. Now, admitting that the statement of seven miles an hour is correct for half the E.M.F., putting all cells in series would not give a speed of 12 miles, but only about 10 miles an hour. But from the curves I have, the average shows that the power required increases at a greater rate than the square, in fact, the power curve stands about midway between the curves of the second and third powers. I once tried the

effect of putting double the number of cells in a 40ft. boat, her normal full speed being just over 7½ miles; the result, with all the cells in, was a gain of half a mile, or a bare eight miles an hour.

Indiarubber.—The United States Consul at Singapore reports that there is a royalty charged on rubber collected from the jungles of Borneo of 10 per cent. *ad valorem*. He distinguishes the different species of the plant furnishing gutta found there as follows: 1. *Manungan pulan*, which comes chiefly from North-West Borneo. It is a *Willughbeia barbidgei*, and is specially identical with the "gutta sing garip" of the peninsula. 2. *Maugan buyok*, said to yield the best gutta of the Borneo forest. It is a *Leuconotis engenifolius*. This species is also found in small quantities on the peninsula. 3. *Manugan manga*, which yields a very good gutta, is possibly a *Willughbeia*, as also is *Surapit*, for the latter yields the same milky exudation as *Manugan pulan*, but is said to be a bad gutta, and seldom collected. *Bertabu*, or *Petabo pulan*, is referred to as of little value as gutta, except, perhaps, for adulterating the better kinds. The other kinds of gutta met with in the Malay Peninsula are: (1) *Singgarip putch*, or *Gutta sudek*; (2) *Singgarip hitam*; and (3) *Gutta jelutong*—the latter is only used for adulterating. The guttapercha production and export is much larger than the trade in indiarubber properly so called. The name is given to the inspissated juice, which is produced chiefly by *Dichopsis gutta*, called by the natives *getah taban merah*, and often confused with caoutchouc. The tree is of large size, from 4ft. to 5ft. in diameter, and from 100ft. to 200ft. in height.

Education.—We have received the prospectus of the day and evening classes at University College, Liverpool, for the session 1892-93. It is of course no news to our readers that some of the ablest professors we have are to be found at this college; Prof. O. J. Lodge occupying the chair of experimental physics, Prof. H. S. Hele-Shaw that of engineering, Mr. Francis G. Bailey being demonstrator in electro-technics, Dr. J. L. Howard demonstrator in physics, Mr. Edward E. Robinson being lecture assistant, and Mr. Wakeling laboratory assistant. There are two courses of lectures on electro-technics, one of them elementary, only to be attended by those who have been through the junior course of physics for the session, the other more advanced, and assuming that the student has attended intermediate physics as well. The syllabus matters to be treated during the ensuing session is found in detail in the prospectus, pages 82 to 84. It is, perhaps, a pity that as yet not one of the technical papers has found it expedient to follow the lead of the *Lancet* as regards an educational number towards the beginning of the autumn session. We merely throw this out as a suggestion, for it can hardly be expected that we, who are rather prone to adversely criticising the action of a good many of the professors, can either obtain their patronage or the necessary information in sufficient time to undertake the task, or even to make a suggestion which may be worth their attention.

Accrington.—It will be remembered that we have mentioned the proposal of the municipal authorities of Accrington to purchase the gas and water undertakings of that borough. One of the members of the Council recently enquired whether the Legal and Parliamentary Committee had prepared any report with regard to the electric light in accordance with a resolution passed a month ago. It appears that no such report has been made, but it was stated that as one of an important character had just been received from Mr. Horsfall, who had been going into the question, the committee will be able to give some information at an early date. Mr. Horsfall thinks that the question of the destructors and the electric light go hand-in-hand, and he estimates that when the destructors are erected they will obtain sufficient power to light the Town Hall and the market, and probably a good deal more. There seemed to be, however, a feeling that the position was a somewhat precarious one, in that the time during which their provisional order ran had expired. The old, old arguments were used, that might be summed up in two words, *festina lente*—the members of the Council evidently being of the opinion that other authorities may carry out experiments, and that they would rest and see the result at no cost to themselves. Progress would be delightful, and certainly hardly characterised as rapid, if every business man was to follow the same course.

Photometry.—Mr. Van Choate suggests a new form of photometry, in which selenium cells are employed to receive the light-rays. The instrument is in the nature of a balance connected with a differential galvanometer, the standard light being arranged to affect one side of the balance, and the unknown strength the other. Two lanterns are required, in which the lights are placed, and tubes of these are arranged axially in line. The light to be measured is placed in the right-hand lantern, the standard lamp being in the left-hand. Each tube contains a selenium cell, that in the tube from the standard lamp being adjustable by means of a pinion, and having an index finger moving along the index. Now, taking the right-hand coil of a differential galvanometer, one of the terminals is connected to the zinc pole of the battery, the other to the selenium cell and through the resistance coil to the copper pole of the battery. Similarly, one of the terminals of the left-hand coil is connected to the copper battery, and the other terminal with the adjustable selenium cell and to the zinc pole. The galvanometer can be brought to zero by adjusting the resistance coil. The selenium cells being alike, if the lamps are equal, the distance between the selenium cells and the respective lamps will be the same; if, however, the lamp to be tested is inferior to the standard, the cell facing the standard lamp will have to be moved until the galvanometer shows equilibrium. The difference in the distance between the selenium cells and the lamps is indicated on the scale, and gives the basis for the calculation of the relative intensities of the light of the two lamps, calculations being made according to the law of inverse squares.

Obituary.—Long since the name of Mr. F. N. Gisborne has faded from the view of present-day telegraphists, but in Canada he has been doing good work. On August 30th he passed away from this sphere, wherein he played a prominent part in the history of submarine telegraphy. It was Gisborne who first directed the attention of Cyrus Field to the question of Atlantic telegraphy, and these two gentlemen worked harmoniously and energetically in the realisation of the project. They lived to see it a complete success. Mr. Gisborne, was born in Broughton, Lancashire, England, March 8th, 1824. In 1842 he started on a tour around the world which lasted nearly three years. He finally settled, in July, 1845, in Canada. But he was not long content with the life of a farmer. He had a keen interest in telegraphy, and in 1847 he deserted his farm for a place in the office of the Montreal Telegraph Company. Not long afterwards he opened the first office of the company in Quebec. He advanced rapidly, and in 1850 he was the chief officer of the Nova Scotia Telegraph Company. About this time he conceived the idea of connecting Newfoundland with the American continent, and though the work led through adversity, and even through prison, he was constant in his efforts, and

finally carried it out, and further, for not only Newfoundland, but Europe was through this initiative connected with the American continent. After the cable was finally laid, Mr. Gisborne was appointed superintendent of the Canadian Government Telegraph and Signal Service, an office that he held until his death. He was the inventor of a number of valuable electric and other appliances. He was one of the original members of the Royal Society of Canada.

Electric Transmission.—Some time ago Mr. E. Griffin read a paper before the Franklin Institute on "The Electric Transmisson of Power," which paper has been published in the September number of the *Journal* of the institute. There are a few conclusions and statements to which we should like to direct attention. He points out various truisms, such as that the latest types of dynamos are built to run with slow armature speed, and in this respect the electrical manufacturers are gradually approaching the engine makers. Engines work most economically under full load. A mean of several electric railway power stations shows the average load to be about 60 per cent. maximum, and in lighting stations running for 24 hours the changes are of course much greater. In the latter case it is imperative that the same plant be divided into numerous units, which can be gradually brought into service according to the demand. The size of the dynamo should be proportionate to the total works of the station. There should never be less than two generating units, and preferably more. With a total of 250 h.p. it would be poor practice to have but one 250-h.p. dynamo. Three eighties would be far preferable. With a total of 2,000 h.p. it would be poor practice to have 25 80-h.p. dynamos. Eight to 100 fifties would be preferable. As we say, these truisms are reiterated in this paper, and cannot be too often driven home, and especially when there are numbers of young engineers attempting to design stations. They are more likely than older men to lack the guiding reins of experience. The paper, however, contains a good deal of information as to various stations all over the world, and in connection with the electric railways of the States it is said that last year no less than 119,264,401 passengers were carried on the cars, and not a single individual has ever been killed or seriously injured by the trolley current. This does not mean that there have not been very sad accidents, but they are accidents similar to those which occur with any system.

Use of Secondary Batteries.—A pamphlet under this title, by Jules Bourquin, is published by Gustave Thiriart, of Liege. This little 24-page treatise is an extract from the *Proceedings* of the Association des Ingénieurs Electriciens Sortes de l'Institut, of Montefiore. In the literature of secondary batteries the chemical action involved in the formation, charge, and discharge, also the management and descriptions of the various types, has been fairly well treated; but hitherto little has been done in the direction of indicating the best conditions under which they may be commercially applied. The treatise before us, however, is an attempt in this direction. In the treatment of his subject, the author divides it into two parts. Chapter I., in which are considered the most efficient methods of charging and discharging the cells, a subject that has been well discussed and fully ventilated in this country, terminates with a *résumé* of the work already done in this direction by various investigators, chiefly continental. Probably many in this country will scarcely agree with the author's assertion that little or nothing has been done in the way of determining the chemical action in storage cells since Gaston Planté gave his invention and the result of his experience to the world at large. Some stress is laid upon the necessity of having an alarm for suitably indicating a hurtful condition of charge and discharge, and the apparatus of M. Fein, of Stuttgardt, devised for this purpose, is alluded to. Chapter II. treats of the best and most commercially economical methods of utilising secondary batteries, whether they be of the pasted or Planté types. Referring to portable accumulators suitable for miners' lamps, the Swan, whose weight is given as 3·2 kilogrammes for an electrical capacity sufficient to give between 10 and 13 candle-power hours, is quoted as being a step in advance; but we imagine that several makers of these commodities can show superior results to this. Altogether, M. Bourquin's little pamphlet will well repay a perusal by all those interested in accumulators.

Prize Competitions.—At the last prize contest instituted by the city of Paris for the best electric meter, the prize of 5,000f. was awarded to Prof. Elihu Thomson. With the desire that this sum should serve for the development of the theoretical knowledge of electricity, he has requested M. E. Thurnauer, general manager for Europe of the Thomson-Houston International Electric Company, to offer a prize for the best work on a theoretical question in electricity, and to organise a committee who should propose the subjects, examine the productions, and decide the prize. The committee has decided that the prize should be given for an investigation on one of the following subjects: 1. The heat developed by successive charges and discharges of condensers under different conditions of frequency, nature of dielectric, and quantity of charge. 2. It has been shown theoretically that when the two surfaces of a condenser are connected by a conducting body, the condenser becomes the source of alternating currents as soon as the resistance of the conducting body decreases below a certain limit. The formula that permits calculating the period of this oscillation has not yet been completely verified. This period of oscillation should be investigated experimentally, under conditions such that the exact measure of resistance, capacity, and coefficients of self-induction may be possible, in order to arrive at a complete and precise verification of this formula. 3. When a condenser made with an imperfect insulating material has been charged and then left to itself, the charge is gradually dissipated. The time necessary for the charge to be reduced to a given fraction of its initial value depends only on the nature of the insulating material. It is proposed to investigate whether, as certain recent theories would seem to indicate, analogous phenomena do not present themselves in metallic conductors, and whether these can be shown experimentally. 4. It is proposed to arrange and systematise our present knowledge of the graphical solutions of electrical problems, and deduce from them some general methods, as in graphical statics. The theses presented may be written in English, French, German, Italian, Spanish, or Latin. They may be in manuscript or printed. The papers must be sent before Sept. 15, 1893, to B. Abdank-Abakanowicz, consulting engineer, 7, Rue du Louvre, Paris.

Cost of Electric Traction.—The West End Street Railway of Boston is now operating 1,000,000 electric car miles per month. In June the revenue electric car mileage was 846,987, in July it was 971,862, and for August it will exceed 1,000,000 miles. The result of this larger electrical mileage is seen in a decreased cost of maintenance and motive power per car mile. In July it was 4·56 cents, against 5·06 cents in June. The total cost of electrical motive power and maintenance in July was 90,320dols., against 87,956dols. in June, and yet the car mileage was 124,875 miles, or 14 per cent., greater. In August, with

1,000,000 miles run, there is no increase in the number of employés. The statement for the month of July is as follows:

	Total.	Electric.	Horse.
Gross receipts	$603,415	$383,149	$220,266
General expenses	27,246	16,666	10,579
Track and car expenses ...	168,716	105,602	63,113
Motive power..................	120,811	50,777	70,033
Total operating expenses ...	373,838	212,589	161,248
Net earnings	229,577	170,559	59,017
Miles run	1,588,663	971,862	616,801
Ratio mileage...................	100	61.17	38.83
Percentage of expenses ...	61.95	55.48	73.20
Earnings per mile run	37.98c.	39.42c.	35.71c.
Expense per mile run :			
Motive power	07.61	05.22	11.36
Other expenses	15.92	16.65	14.68
Total expenses	23.63	21.87	26.14
Net earnings per mile run...	14.45	17.55	9.57

The following table shows gross and net earnings by months for May, June, and July compared with last year:

Gross earnings:	1892.	1891.	Inc.	Dec.
May	$540,846	$521,086	$19,760	—
June	600,450	551,592	48,858	—
July	603,415	555,739	47,673	—
Total	$1,744,711	$1,628,417	$116,294	—
Expenses:				
May	$339,306	$364,210	—	$24,904
June	368,416	353,135	$15,281	—
July	373,838	366,317	7,521	—
Total	$1,081,560	$1,083,663	—	$2,102
Net earnings:				
May	$201,539	$156,875	$44,664	—
June	232,033	198,456	33,577	—
July	229,577	189,422	40,155	—
Total	$663,151	$544,754	$118,396	—

Electric Cranes.—From the Institution of Civil Engineers' *Abstracts* we note that Mr. C. J. Bates has in the *Railroad Gazette* described a "100-ton" (*i.e.*, 200,000lb.) crane built for the Baldwin Locomotive Works by W. Sellers and Co., of Philadelphia. The crane consists of a rolling bridge of two parallel girders of 74ft. 8in. span, and 7ft. deep out to out, placed 9ft. 3in. apart, and carried by four 5ft. wheels, with double-flanged steel tyres, the wheel base being 14ft., and the rails weighing 360lb. per yard, and carrying a rack of 2¼ pitch and 4in. face in which work the travelling gear wheels. As the crane has to lift a locomotive by both ends, there are two hoisting trolleys, which run on rails carried by the lower flanges of the main girders, and each trolley is in itself a complete hoisting machine. The source of power is a dynamo, the terminals of which are connected to two $\frac{7}{8}$in. rods of copper, supported on yellow pine strips and glass-insulated. On the rods run a pair of small four-wheeled trolleys of the Wheeler type for picking up current. Each trolley is coupled to a 40-h.p. United States Electric Light Company's motor of constant speed, shunt wound for a 220-volt current. Their speed is 500 revolutions per minute. They stand on the top of the bridge over the operator's platform, and are belted to the gearing below, which operates the hoisting trolleys, one set of gearing being on each side of the bridge. The two systems are connected by a belt across the bridge, and, so far, there has been no burning of either motor, as might occur if one motor overran and turned the slower one into a dynamo. The systems of gearing, made up of various clutches, etc., transmit power to the hoisting trolleys through three square shafts to each trolley, and on each trolley, for hoisting or lowering, there are four speeds—viz., 5, 10, 20, and 40ft. per minute, and two traversing speeds, 50ft. and 100ft. per minute. A special clutch holds the weight, and prevents a "run" when changing speed or direction. The hoisting-block has two sheaves, and the chains are also in two parts, and the winding of the drums runs towards the middle, so that an object is lifted vertically. Each trolley will lift 100,000lb. On one trolley there is a small 5-h.p. Wenstrom motor and hoisting gear for small weights. There are nine levers to be worked by the operator, and they are arranged to be moved in the direction of motion intended to be given to the loads, as far as practicable.

Miners' Electric Lamp. — The following note appeared in the *Times* of a few days since. We give it for what it is worth, but in our estimation the practical value is infinitesimal. However, we may be wrong, and for the sake of miners hope a suitable lamp has been obtained: "Various attempts have been made to supersede the miners' oil lamp in collieries and other underground workings by the electric light, and of late considerable progress has been made in this direction. The attempts have largely been made in connection with secondary or storage batteries, but it is considered that the conditions of working can best be met by a lamp taking its current from a primary battery, which principle has also been laid under contribution. The main difficulties which have hindered the general introduction of electric lamps underground appear to have been excessive first cost and heavy cost of maintenance, limited duration of light, great weight, and the necessity of skilled labour for their adjustment. These hindrances appear to be overcome in the electric lamp invented by Colonel Engledue, R.E., of Byfleet, Surrey, which constitutes the latest example of electric lamp for mining purposes. In this lamp the current is derived from a primary battery, which is enclosed in a wood case measuring 6½in. high by 5in. wide and 3in. thick, and having a middle partition forming two cells. The cells are lined with lead, to which are attached carbon plates, four in each cell, thus bringing the carbons and lead into electrical circuit. The top of the battery is hermetically sealed by an ebonite cover, which is screwed down to the wood casing, an india-rubber washer being interposed. Two ebonite plugs are screwed into the ebonite cover, one over each cell, each plug carrying a round zinc element which dips into the depolarising resolution. The lamp has a fixed wood cap, and contacts are made in the usual manner with a small glow lamp placed in front of the case and protected by a small lantern with a reflector. The electrolytic fluid consists of a solution of sulphuric acid, hydrochloric acid, and bichromate of soda, with which the cells are charged to within about an inch of the top. After the lamp has been running for about four hours it is turned upside down, and instantly fitted for work again by the aid of an ingenious handle, which can be reversed and locked by a simple movement and without detaching it from the lamp. The reversal gives the zinc elements full immersion in the electrolytic fluid, and the lamp yields a light for another six hours or more, bringing the total duration of light up to over 10 hours, the practical constancy of the light being maintained. Tests of this lamp in workings show that it gives a sufficient light for mining purposes for 10 hours or longer, while the cost of maintenance is stated to be about 6d. per week per lamp. The first cost of the lamp is put at 15s., while its weight when charged for use does not exceed 5lb. In view of the importance in collieries of a light which cannot be exposed without being instantly extinguished, it is to be hoped that the lamp under notice, which appears to meet the requirements of both masters and men, will find a speedy and wide adoption."

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

VIII

(*Continued from page 183.*)

RESISTANCE, *continued.*

Post Office Forms of Wheatstone's Bridge. Some of the earliest examples of the Post Office form of Wheatstone's Bridge consist only of the variable known resistance R_1, and the two ratios R_2 and R_3, together with binding screws for connecting up the galvanometer, the battery, their contact-makers or keys, and the unknown resistance R. An example of this class of instrument is shown in Fig. 15, which illustrates what is known as the Post Office Wheatstone's Bridge, Old Form. The battery circuit is shown with a key K_1 for reversing the direction of the current, while the galvanometer has a simple contact maker K_2. With the exception of the resistance coils themselves, which are shown dotted in Fig 15, this form of the apparatus has no underboard or concealed connections whatever,

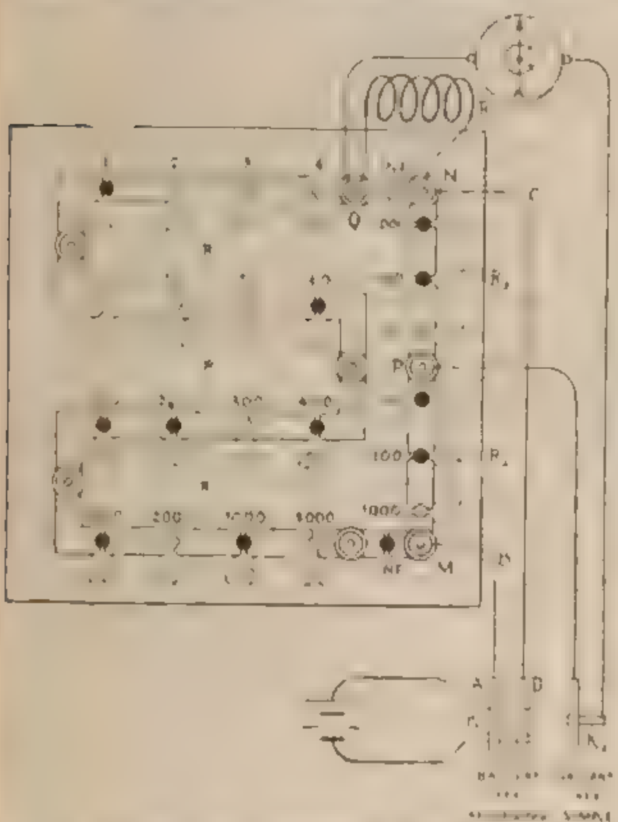

FIG. 15.—Post Office Wheatstone's Bridge—Old Form.

so that the whole arrangement will be readily understood from the diagram, which shows the apparatus connected up in readiness for making a measurement.

The resistance coils, the construction, calibration, adjustment, etc., of which will be treated in a subsequent article, usually consist of lengths of high-resistance insulated wire wound on bobbins or spools which are fixed underneath the baseboard, the ends of the coils being connected in such a way to the brass or gun-metal junction-pieces above, that when the plug between any two adjacent junction-pieces is removed from its seating, the circuit then includes the coil directly beneath. Each coil is carefully calibrated so as to have the exact resistance indicated on the baseboard above. The wire, which is usually of German silver, platinoid, or platinum-silver alloy for the better class of instruments, is wound double on the bobbins to prevent self-inductive action in a coil when a current is sent through it. The baseboard of the instrument, on which the junction-pieces are fixed, consists of a slab of insulating material, usually vulcanite, and the tapered plugs for inserting between the junction-pieces when it is desired to cut out the resistances bridging the gaps between them are usually of the same metal as the junction-pieces themselves, and are provided with vulcanite insulating handles. These plugs are all carefully fitted to their seatings so as to afford a large surface of contact which will offer little or no resistance to the passage of an electric current, and they are made interchangeable so that any plug can be used for any gap.

FIG. 16. Post Office Wheatstone's Bridge—New Form.

Many forms of short-circuiting junction plugs have been from time to time suggested, but the very slightly tapered round plug (of which those used in the instrument illustrated in Fig 16 are examples) now almost universally used, has been found to give the best results owing chiefly to its self-cleaning properties and the excellent contact obtained through the screw-like wedging action when it is pressed and turned in its socket

In the Post Office Wheatstone's Bridge, New Form, of which a commercial example is shown in Fig. 16, and a diagrammatic representation (showing all the connections made in readiness for measuring a resistance) in Fig. 17, the galvanometer and battery keys are both incorporated in the instrument itself, as well as the ratios R_2 and R_3 and the known variable resistance R_1. Besides the addition of the keys K_1 and K_2, it will be seen on comparing Figs. 15 and 17 that the known variable resistance R_1 is arranged in a more compact manner in the new form of the instrument than in the old. The underboard connections from the keys are shown

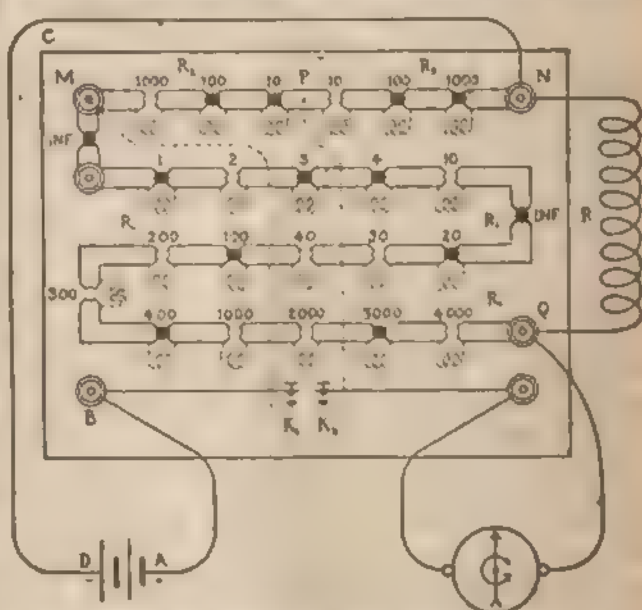

FIG. 17.—Diagram of Post Office Wheatstone's Bridge—New Form.

dotted in Fig 17, the dotted lines representing thick pieces of copper wire which offer practically no resistance to the passage of an electric current through them. The battery key K_1 is connected to M, the point where the ratio R_2 joins the known variable resistance R_1, and the galvanometer

key K_2 is similarly connected to the point P between the two ratios R_2 and R_3.

In both of the examples here shown the coils in the variable known resistance R_1 are arranged on the 1, 2, 3, 4 system, and the two ratios R_2 and R_3 consist of three coils of 10, 100, and 1,000 ohms each. In the New Form, Fig. 17, both of the infinity plugs must be in their places while a measurement is being made, but in the Old Form, Fig. 15, the plug between the binding-screws Q and N must be removed, so as to throw into circuit the unknown resistance R whose ends are connected up to Q and N.

In the example of Post Office Wheatstone's Bridge, New Form, shown in Fig. 16, the instrument is fitted in a polished mahogany case provided with a dust-proof lid which renders it very compact and suitable for travelling.

The binding-screws used in the various forms of Wheatstone's Bridge, and in a large variety of other electrical instruments, usually consist of a shoulder and projecting screw on which are fitted a pair of faced-up nuts with milled edges, two nuts being provided to facilitate the connecting up of two or more separate wires to the same binding-screw. Sometimes additional provision for making connections is afforded by an extra nut on a stud projecting at right angles from the side of the binding-screw, instead of putting both the nuts on the same spindle.

To render these instruments more serviceable and convenient when used for throwing resistances into circuits or for other purposes, it is usual to provide them with more binding-screws than are absolutely necessary for ordinary measurements on the Wheatstone's Bridge principle. If in using either of the instruments illustrated in Figs. 15-17, in the ordinary way, it is found that the known variable resistance R_1 is too small, additional resistance may be thrown in by removing the infinity plug at the bottom right hand corner in Fig. 15, or at the top left-hand corner in Fig. 17, and connecting up the additional resistance to the screws at the side of the gap. Provision for throwing in additional resistance when necessary is similarly allowed for in the various other forms of these instruments.

(To be continued.)

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

I.—EVOLUTION OF ELECTRICAL ENGINEERING.

ADVANTAGES OF THE ELECTRIC LIGHT.

A pure and healthy atmosphere is dependent upon the amount of oxygen present, and the following are the percentages of gases which, being mechanically mixed, form the atmosphere:

Oxygen	23 per cent.	by weight.
Nitrogen	77 „	
Total	100	

There are, in addition, very small quantities of carbonic acid gas (CO_2), hydrogen, ammonia, and organic matter.

All substances and matter, when burning, consume oxygen—that is to say, the act of combustion of any matter signifies the chemical combining or mixing of the vapours of the burning matter with the oxygen of the atmosphere. Hence if matter be burnt in a closed vessel containing atmospheric air, the matter would continue to burn until it had abstracted all the oxygen out of the air, and when that stage had been arrived at, the combustion would cease through lack of oxygen; the volume of the new gas thus given off is often poisonous, according to the nature of the article burnt. The most common ways of obtaining light is by oil, candles, or gas. Of these three, candles are the most unhealthy light, because they abstract more oxygen from the air than the other forms of illumination; all three vitiate the atmosphere and give off poisonous fumes, the carbon which they contain mixing with the oxygen from the air, and so producing the deadly carbonic acid gas, known to chemists as carbon dioxide, or CO_2. The operation of breathing has a similar effect on the atmosphere—pure air is inhaled by the lungs, but impure air, containing carbonic acid gas, is exhaled. It is this that makes a room close or stuffy when a person has been sitting in it any length of time with doors and windows closed. One gas jet of 14 c.p. consumes about 20 cubic feet of air per hour. A man with good respiration will consume about four cubic feet of air. From this it will be seen that one gas jet vitiates a room to the same extent as four persons would do.

The following table shows forcibly the weight of the preceding remarks, each illuminant giving a light of 12 standard candles for one hour:

Illuminant.	Cubic feet of air consumed.	Cubic feet of carbonic gas produced.	Cubic feet of air vitiated.	Heat evolved in lbs. of wat'r raised 10°F.
El'ctric light	None.	None.	None	13¾
Common gas	17¼	3¼	348¼	278¾
Paraffin oil .	34	4½	484	362
Wax candles	42	6	632¼	383

Illumination by means of the electric light keeps the atmosphere pure and cool. Respecting the first claim—namely, that of purity—the proof is made self-evident by simply stating that the light is enclosed in an air-exhausted and hermetically-closed glass bulb, thus absolutely severing the light from any contact with the atmosphere. Under these conditions the lamp filament cannot burn, through absence of oxygen; hence there can be no evolution of heat from combustion. Most people fancy that the electric light does not give out heat; this is a very great mistake, since there can be no light without heat. When a substance burns, its atoms unite with the oxygen atoms of the atmosphere, and this chemical affinity causes such a great evolution of heat that the particles are raised to a state of incandescence, or white heat, consequently we obtain light.

In the case of an electric incandescent lamp, the small amount of heat evolved from it is due to the high temperature of the lamp filament, and on account of the vacuum in the lamp there is no conducting medium for the heat, which is thereby much diminished. This is shown by taking in the hand a glow lamp that has been burning some hours; it will be found that there is a comfortable degree of warmth without burning the hand. Compare this with the effect of placing the hand close to a gas jet of equal candle-power, and a practical example is found at once of the relative heating properties of the two illuminants.

The great value of the electric light and the boon it confers cannot be over-estimated, particularly when it is introduced into manufactories, mills, shops, etc., where the articles about are of a highly inflammable nature, and the danger of fire so great in the presence of naked gas light. The act of lighting by electricity can be done automatically and instantaneously throughout the whole of a large establishment; this avoids the risks and dangers of gas lighting by hand, as well as time and labour, and therefore expense in so doing.

The best proof that can be put forward as to the great safety in the use of the electric light, is that the insurance companies look upon its introduction with favour, yet it must be borne in mind that the insurance people have had to draw up very drastic rules in order to protect themselves and the public, and the electrical industry should be greatly indebted to them on this score, because without any such compulsion unscrupulous firms would scamp their work, thus throwing discredit upon the whole industry. These kind of people never hesitate to do electrical work at prices with which a good firm putting in good work cannot possibly compete. Following in the wake of this type of contractors comes a long train of nondescript individuals, who take unto themselves the title of electricians, electrical engineers, or anything else to the purpose that suits their fancy. These enterprising gentry recruit their ranks from tinkers, plumbers, ironmongers, bellhangers, and such like, and trade upon the ignorance of the public. This is one of the attendant evils that dog the progress of a new industry—a veritable "old man of the mountain," and the same thing occurs in the development of every industry. Time only can cure it. In conclusion, it may be said that *the electric light is the safest of all illuminants, provided that the work of instalment is well and conscientiously carried out.*

Before concluding these remarks, there should be pointed out one other advantage which the electric light possesses, and a matter of paramount importance—namely, the health and personal comfort. Who is there who has not felt the exhausting and injurious effects of a heated and contaminated atmosphere? The stifling feeling in a theatre, or any other place where there is a number of people, is partly due to them, and partly due to the gas lights. The same applies to workrooms of every description. That a substantial improvement is wrought by the introduction of the electric light there is no shadow of a doubt. In the General Post Office, St. Martin's-le-Grand, the electric light costs £700 per annum, but a healthier atmosphere is procured, and the great benefits and comforts which it bestows on the employees is such that it has diminished the hours of absence two hours per day. In addition to this, the staff are able to work better and quicker, due to the absence of the lassitude so often felt in heated atmospheres. Mr. Preece, the chief electrician, considers the increased amount of work obtained from the staff very nearly pays for the cost of lighting.

Cost of Electricity v. Cost of Gas.

A great deal of misleading and incorrect matter has been published concerning the relative cost of gas and electricity. Some writers have made electricity two to three times the cost of gas; others, again, have erred in the opposite direction, and tried hard to show conclusively that it is quite as cheap as, if not cheaper than, gas. The author is of opinion that neither party is correct. The cost of electricity depends a great deal on the circumstances and conditions of production. To show clearly what is meant by this, take the case of a large mill, owner, who has, say, a 200 h.p. steam engine; from this, 20 h.p. can easily be reserved for driving a dynamo, very little more coal will be burnt, scarcely any attention required, the only outlay of money being for the dynamo and fixing up of lamps—here the cost of the light will be far below gas, possibly not much more than one half. Now, take the other extreme, buying current from an electric supply company in London; the general charge is 7½d. per unit, and this works out to an equivalent cost of 6s. 4d. per 1,000 cubic feet of gas, which is more than double the average cost of gas at 3s. per 1,000 cubic feet. From these two examples the reader will at once perceive how absurd it is to make a sweeping solution of a problem which admits of two such diverse interpretations. A detailed comparison between gas and electricity will now be made, assuming the electricity is supplied from a central electric light station, just as gas is supplied from gas works, for this is the way the general public will obtain their electricity.

(a) Comparison with a Glow Lamp.

An ordinary sized gas jet, such as is found in all private houses, may be judged to give out 14 actual candle power, when in good condition, the consumption of gas being taken at the rate of five cubic feet per hour, the gas being of good quality and at a normal pressure. With gas at 3s. per 1,000 cubic feet, the cost of five cubic feet would be 0·18 penny, so that one gas jet of 14 c.p. burning for the space of one hour would cost 0·18 penny, or little less than one-fifth of a penny, or one penny if burning for five hours; and for 1 c.p. the cost would be 0·013 penny or one seventy-seventh ($\frac{1}{77}$) of a penny, or one penny if burning for 77 hours—1 c.p. being taken as the standard measure of light as given out by a pure spermaceti wax candle which consumes 120 grains of wax per hour. Passing on now to electricity, assume the price of current is 7½d. per Board of Trade unit, this being the charge made by the Metropolitan Supply Company in London, and is a fair average price. A unit signifies a certain amount of electrical energy (1,000 watts) acting for the duration of one hour. An incandescent lamp of 16 actual candle-power requires 56 watts or 3·5 watts per candle-power; this works out at 0·025 penny, or $\frac{1}{40}$ penny, per hour for 1 c.p. Besides this cost there is the cost of the lamp itself to be considered. An incandescent lamp costs 3s. 9d., and on an average has a life of 1,000 hours, at the end of which time the filament breaks, or the lamp becomes so blackened that its light-capacity is worthless. Therefore, the cost of the lamp comes to ·0028 penny, or one three hundred and fifty-seventh of a penny ($\frac{1}{357}$ penny) per hour of candle-power. Adding these two costs together we have

Cost of current	=	·0250 penny
Cost of lamp	=	·0028 „
Total	=	·0278 penny.

Hence	1 c.p. per hour from gas	=	·013 penny
	1 „ „ „ electricity	=	·0278 „
or	14 „ „ „ gas jet	=	·18 „
	16 „ „ „ glow lamp	=	·44 „

Gas being reckoned at 3s. per 1,000 cubic feet, and electricity at 7½d. per 1,000 watt hours. ·44 penny means a trifle under one halfpenny, so that in practice it is usual to take the running cost of a 16 c.p. glow lamp at one halfpenny per hour. Similarly, the cost of an 8 c.p. glow lamp is put down at one farthing. Of course this only applies when the cost per unit = 7½d. If the cost be less than 7½d., say 6d., which is what the St. Pancras Vestry charge, then the cost of a 16 c.p. glow lamp per hour would be $\frac{1}{2} \times \frac{6}{7\frac{1}{2}} = \frac{2}{5}$ penny nearly. When the number of lamps used and the hours that they are burning are a fixed number, say in a business establishment, it is very easy to arrive at the total cost of the light. Suppose 50 lamps of 16 c.p. are lit at dusk every day, except Sundays, until 8 p.m., upon referring to the table of the lighting hours given at the end of the book, it is seen that the number is 742; as Sundays are excluded, one-seventh of this ($\frac{742}{7} = 106$) must be deducted, leaving 742 − 106 = 636 hours of lighting, so that ½ × 50 × 636 = 15,900 pence = £66 5s., using electricity at 7½d. per unit.

From the figures given above, it is seen that electricity in the form of glow lamps costs more than double gas, since ·0278 is more than twice ·013, therefore the equivalent cost of gas to bring the price up to that of electricity must be—

$$\frac{3 \text{ shillings} \times \cdot 0278}{\cdot 013} = 76 \text{ pence} = 6s.\ 4d.$$

The table below is taken from a paper written by the author, entitled "Shall Gas Undertakings Supply Electricity?" (see *Transactions* of the Incorporated Gas Institute, 1890), and is worked out to give the equivalent cost of gas for different prices per unit of electricity, the figures here being corrected ones.

	Pence.								
Per unit of electricity	4	4½	5	5½	6	6½	7	7½	
Per 1,000 cubic feet of gas	42	48	53	58	64	69	74	79	
Per unit of electricity	8	8½	9	9½	10	10½	11	11½	12
Per 1,000 cubic feet of gas	85	90	96	101	106	112	117	123	128

The above figures relate only to lighting by means of incandescent or glow lamps, and not to arc lamps. It will be observed that by multiplying the price per unit of electricity by the number 10½, we obtain the corresponding equivalent cost per 1,000 cubic feet of gas. For example, let 5½d. be the cost of a unit, then 5½ × 10½ = 58, and on referring to the table it will be seen that 58 is given as the equivalent cost of gas.

(b) Comparison with an Arc Lamp.

When the greatest economy is required, arc lamps should be used; this kind of electric light is particularly suitable for large spaces, such as building yards, warehouses, etc. A 1,200 nominal candle-power arc lamp takes about 330 watts, or one-third of a unit, and may be said to give out about 480 actual candle-power when a thin ground glass globe is used. With electricity at 7½d. per unit, this works out to ·0053 penny per candle-power per hour. There is now to be added the cost of the carbon consumed in the lamp. This may be put down at ⅗d. per hour, therefore this equals ·00125 penny per candle-power per hour. Adding both together, we have

Cost of current	=	·0053 penny
„ „ carbon	=	·00125 „
Total	=	·00655 „

Hence an arc lamp giving 480 c.p. actual, or 1,200 nominal, costs about 3d. per hour.

It was found that the cost of gas at 3s. per 1,000 cubic

feet was ·013 penny per candle-power per hour—hence the equivalent cost of gas is

$$\frac{3 \text{ shillings} \times \cdot 00655}{\cdot 013} = 18 \cdot 1 \text{ pence, or little more than 1s. 6d}$$

From this it appears that an arc lamp of 480 actual candle-power, when using a thin ground glass globe, only costs about one half the price of an equal amount of light from gas. This is, taking gas at 3s. per 1,000 cubic feet, and electricity at 7½d. unit, and with these same prices for gas and electricity, it was shown that a glow lamp cost more than double that for an equal amount of light from gas, hence the arc lamp costs less than one fourth the cost of a glow lamp for equal candle power. In the case of the glow lamp, the equivalent cost for gas was obtained by multiplying the price per unit by 10½, and since the arc lamps costs less than one-quarter of the glow lamp, therefore multiplying the price per unit by 2½ gives the equivalent cost for gas in the case of arc lamps.

The tabulation below shows in a brief form the respective costs per candle power per hour for arc lamp, glow lamp, and gas jet; also the cost of their respective full candle-power, and finally the ratio of their cost, taking gas as a standard at 100.

Illuminant.	Cost of 1 c.p. per hour.	Full c.p. per hour.	Ratio.
Arc lamp.	·00655 or [illegible] penny	For 480 c.p. = 3 pence	51
Glow ,,	·027 or [illegible] ,,	,, 16 c.p. = ½ penny	207
Gas jet.	·013 or [illegible] ,,	,, 14 c.p. = ¼ ,,	100

Take an establishment lit by arc lamps, say 10 in number, and running the same hours as was given in the example with glow lamps, that is 636, excluding Sundays. At 3d. per lamp per hour, this $= \frac{636 \times 3 \times 10}{20 \times 12} =$ £79. 10s., and is the cost per annum for illuminating power equal to $10 \times 480 = 1,800$ candles, or about 342 5ft. gas jets.

All the above calculations have been based on the standard size of lamp, or that size most commonly used—that is, 16 actual candle-power for glow lamps, and 1,200 nominal, or 480 actual, for arc lamps. As the lamps, both glow and arc, increase in candle power or size, so the electrical power consumed by them becomes slightly less in proportion to the candle power. Hence, their cost will become slightly less also, but against this advantage it must be remembered there is a greater concentration of light, which is a disadvantage. This matter will be discussed fully further on.

Economics of the Electric Light.

So far nothing has been said concerning the numerous small savings that electricity effects. The above detailed comparison of cost simply refers to direct charges. Upon examination, we shall find that the direct charges, or what may be termed "prime calculated cost," will be considerably altered in value. Take into account the great waste of gas that occurs through lights being left burning unnecessarily. How many times a day are gas jets left full on upon the occupier leaving a room for, say, 10 minutes? It is too much trouble to turn the gas out, and particularly to relight it, matches are not always at hand, and groping about in the dark is very unpleasant—a feat more often than not attended with knocking your head or shins against articles anything but soft. Turning out the gas or lowering it may seem to effect a very trifling saving, but it is these trifles that soon add up into a respectable total, and "many a mickle makes a muckle." Three times 10 minutes every day signifies close on a couple of hundred hours per annum. Now perform this operation on half-a-dozen gas jets or glow lamps; it reaches the total of nearly 1,100 jet or lamp hours, or equivalent to one jet or lamp burning for 1,100 hours. In the case of gas this signifies not far off a sovereign wasted, and in the case of electricity more than a couple of sovereigns saved. Where electricity is employed as a lighting medium there is not the slightest excuse for such needless waste, because by fixing the switch close by the entrance door the light can be immediately switched on before entering the room, similarly the light need not be switched off when leaving the room until just at the door. Only those who have experienced it can appreciate the comfort of the electric light in a bedroom, with the switch fixed close to the bed head, and ready t light up or turn out in an instant. Another matter of con siderable importance is the great saving that electricit ensures with regard to expensive decorations, whethe metal work, paint, curtains, and draperies of delicate hue moulding, statuary, and the thousand and one beautifu things that adorn a handsome hall or room. Such place as theatres, hotels, public buildings, etc., recognise thi and it is common knowledge that some of the highly decorate places of amusement save a very heavy sum annually, whic inevitably must have been spent had gas been the illuminan Whilst speaking about amusement places, hotels, etc., it ma readily be inferred that those which possess the cool atmo sphere due to electric lighting are more likely to, and in fac do, obtain a greater share of patronage than the others, othe things, of course, being equal. Each reader can now plac his own figure of value on the foregoing economic featur of electricity, and this, deducted from the "prime calculate cost" of electricity, will give a fair idea of the "true absolu cost" of the electric light as compared with gas.

(To be continued.)

ON THE PHYSICS OF THE VOLTAIC ARC.*

BY PROF. SILVANUS THOMPSON, F.R.S.

The author said if one measured with a voltmeter th difference of potential between the two electrodes of th arc you find, when the arc is steady, the total voltage a observed is something over 40 volts, and it is known tha part of this varies with the length of the arc and th current sent through the arc, and that part is practicall independent of either the current or the length. There i a constant part and another part, which varies nearl directly as the length of the arc when the current is co stant, and nearly inversely as the current when the lengt of the arc is constant. A useful approximate formula fo the steady arc is $e = a + b\frac{l}{i}$, where a and b are constant l the length of the arc, and i the current. The constant varies between 35 and 39 volts; whilst when l is given i millimetres and i in amperes the constant b has value between 8 and 18.

Now, this constant part of the voltage, which is indepe dent of the strength of the current for an invariable lengt and independent of the length of the arc for an invariabl current, is sometimes called the apparent back E.M.F. of th arc. The arc acts as though it were the seat of a bac E.M.F. I am not saying there is actually one, only that acts as though there were. It is possible to account for th thing equally well by saying that there is somewhere in th arc a resistance which proportions itself always inversely t the current. Now, how can any resistance proportion itse so to the current? It can only do so in the following wa If there is at any one surface of the arc a something equiv lent to a transition resistance, then if that varies inversel with the area over which it takes place, and if the area ov which it takes place is proportional to the current, then yo might have something of the kind to explain this. Som years ago I explored the question of the seat of this su posed back E.M.F., and established, by means of th measurements made with a third movable electrode, that th seat of this E.M.F. was at the crater. This was when takin the ordinary method of producing the arc between two carbo electrodes, an upper and a lower. I explored where th great drop of potential, 35 to 39 volts, occurred. I foun that the drop of potential along the arc only amounted t a few volts, and where the great drop took place was a the surface of the positive electrode or crater. This where most of the work of the arc is done. That bein settled as to position, the next question was, what was th physical process going on there which would require suc absorption of energy which made this great fall of voltag and I could only account for it at the time by supposin that the volatilisation of the carbon required it. I was le to this by various reasons, one being Captain Abney's di covery that the surface of the crater is always of an equ

* Paper read before the British Association at Edinburgh.

intensity; the brilliancy for the same quality of carbon per square centimetre was always the same. I was led by that to think it must be simply a question of volatilisation.

Quite recently, however, Mr. Crookes has made the observation that the flaming discharges produced by alternating electric currents at very high rates of alternation and very high voltage, are really endothermic flames of nitrogen and oxygen; in other words, those flaming discharges are simply flames which, instead of giving out heat, absorb heat. Now, in the voltaic arc, as produced in air, something of this kind may occur. There must be a temperature high enough to bring about for the time being the combination of nitrogen and oxygen. We know from Prof. Dewar that such combinations are going on. The question consequently occurred to me whether this had anything to do with the voltage of the arc; and within the last month I have made a number of experiments to put this particular point to the test. A number of experiments were made in my laboratory to test whether the possible combustion of nitrogen and oxygen together had anything to do with the E.M.F.'s there observed. We did this by surrounding the arc by a glass tube, into which we could introduce a number of gases, say oxygen, nitrogen, carbonic dioxide, hydrogen, and so forth. Using always short arcs, and waiting until the current was adjusted to 10 amperes and the arc adjusted to the exact length, we found it does not really make one volt difference. The back E.M.F., or whatever it is, is independent of the surrounding atmosphere.

Incidentally we have observed several effects—namely, that when chlorine and carbonic oxide are used as the atmosphere in which to produce the arc, the crater takes a quite different form from that of the usual arc. The carbon is flattened over the end instead of hollowed, and the negative carbon is also a very obtuse cone. Also when the arc is made with hydrocarbon or coal gas around it the crater is formed, but the edges do not burn away as they do when the arc is made in air. Consequently, there is a regular sooty deposit all round, and the arc is formed up inside a sort of cage. When the arc is made in oxygen both the carbons burn away very fast. Instead of their ordinary consumption there is an extraordinary consumption, which burns them down conically a long way. We have also observed in bringing these gases to the outside of the arc it is necessary that they be introduced gently, without violent draughts, because with even a gentle current of gas the voltage is altered. By blowing on an ordinary arc in air the voltage has been made to rise to as much as 75 volts.

The experiments were conducted by Mr. Eustace Thomas, one of the demonstrators, and by Mr. Portheim, one of my students, to both of whom my thanks are given. There still remains much to do in measuring with exactitude the small variations which may be due to endothermic actions

PORTABLE ACCUMULATORS FOR STAGE EFFECTS.

In the early part of this year we had occasion to notice in these pages some novel electrical effects as shown in the Crystal Palace pantomime, "The Forty Thieves." Recently we have had an opportunity of seeing a further development in this direction in the Crystal Palace ballet, "Little Red Riding Hood."

FIG. 1.—Electric Head Dress.—Back View.

FIG. 2.—Electric Head Dress.—Front View.

It is well known that Mr. Oscar Barrett, the able and energetic manager of the Crystal Palace Theatre, is one of the pioneers of electric lighting for stage purposes. Owing to the pronounced success achieved by the Lithanode Company's batteries at Christmas, Mr. Barrett was encouraged to still further extend their use in his summer production. As a result, a series of charming and beautiful effects have been produced.

A number of ladies in this exceedingly pretty ballet have been supplied with small lithanode accumulators and lamps. As shown in Fig. 1, the batteries are dropped into a small satchel which is securely fixed to the dress. Two silk-covered flexible wires serve to carry the current up to a small four-volt lamp, which is held by spring terminals. The battery used is small and compact, and weighs about a pound. The incandescent lamp is fixed in the centre of a bright metal star with radiating arms, as represented in

Fig. 2. Forked terminals fixed on the ends of the connecting wires serve to complete the circuit between lamp and battery, and these afford a method of instantaneously throwing the lamp in or out of action. The small glow lamp requires from 0·6 to 0·8 amperes and four volts to fully light it. Each cell has a capacity of 1·5 ampere-hours, a capacity quite outside the maximum requirements of the performance. The battery consist of two cells, which are mounted in a thin metallic containing case.

A special feature in these batteries is the precaution taken to prevent any possibility of leakage of the electrolyte, the escape of which has unfortunately been the great drawback to the employment of all forms of batteries for personal or stage decoration, and, as a consequence, although 39 of these batteries have been used at each of the 100 performances given, no accident or damage of any kind arising from this cause has occurred.

Viewed from the front, the effect of the electric lamps is most charming. Each little lamp appears to emit rays much in the same way as a veritable star, and the light reflected from the bright metal background darts about in every direction. It seems almost incredible that such a brilliant effect can be produced from so minute a source of light. A casual onlooker would be inclined to judge the lamps as being from 3 c.p. to 4 c.p., but this enhanced effect is doubtless due to the contrast between the electric light, which is nearly white, and the yellow gas light which forms the background.

In addition to the light shown in Figs. 1 and 2, other novel electric effects have been introduced. In one of the scenes the indispensable "good fairy" is supposed to descend from the clouds to earth, and being somewhat electrical she naturally makes for the nearest and most prominent point, which in this case happens to be a hollow tree. In this piece of stage property the lady is supposed to secrete herself, and she ultimately emerges just in time to frustrate the designs of the wicked fairy. How to produce a halo around the fairy-like form while enclosed within the tree was a problem which could not readily be solved by the employment of the ordinary illuminants; but Mr. Barrett seems to have successfully overcome this difficulty by introducing the electric light. To this end a number of small incandescent lamps are fixed within the tree, and these being backed by reflectors cast their light upon the figure as soon as the current is switched on. This arrang ment is shown in Fig. 3.

Fig. 3. Electrical Effect in Hollow Tree.

In the hut scene, which piece of apparatus is push bodily on to the stage, a glowing fire is represente Under ordinary conditions the fire would be produced b gas jets, which are exceedingly unsafe and not altogethe suitable. Here again, however, electricity is called in, an a few small glow lamps worked from a battery, which fixed to the scenery and goes on with it, gives the desir result.

From time to time during the summer months dramat performances are given at the Crystal Palace. On th occasion of the visit of "Niobe" from the Strand Theatr the management were somewhat at a loss to produce th electrical sparking which is supposed to bring Niobe life.

This difficulty, we are told, was soon overcome by utilisi some of the small lithanode cells to produce a flashing ar which piece of apparatus was fixed at the base of th figure. Again, a similar effect was produced on the visit Mr. Arthur Roberts with his "Two Lovely Black-Ey Susan" company. In this case an electric lamp wa placed in the lighthouse, and was made to appear a vanish at the will of Mr. Roberts, much to the amuseme of the audience.

Doubtless the success of the lighting we have just describ is due to the fact that the whole arrangement was plac in the hands of the Lithanode and General Electric Co pany, they on their part undertaking the recharging a maintenance at a stated charge per lamp per week.

We have probably said enough to show the enormo possibilities for both fixed and portable electric lig when used for stage lighting. It certainly does se somewhat strange that hitherto so very little should ha been done in this direction. A light so safe and eas managed, and capable of so many applications, must sure supersede all others at no very distant period. We a pleased to see theatrical managers co-operating with el trical engineers in the way that Mr. Barrett and the Lith node Company seem to have done. We believe that l affording each other assistance to their mutual benefit ma beautiful, safe, and original lighting effects could be p duced on the stage which would come as a great a pleasant surprise to many of us.

THE

ELECTRICAL ENGINEER.

TO CORRESPONDENTS.

LOOKING FORWARD.

It was Tennyson who sung in "Locksley Hall"—

"When I dipt into the future far as human eye could see,
Saw the vision of the world and all the wonder that would be."

and descending from song to story, it was the able engineer to the Kensington Vestry who, at the meeting of Municipal Engineers, as a section of the Sanitary Institute, jocularly remarked to his fellow-members that Kensington was looking forward to inaugurate the time when dust-bins would be emptied by electrical means. You press a button and electricity will do the rest, was his refrain. That good time coming is still "the vision of the world," but the idea is not so far-fetched as some of those present seemed to think it to be. Mr. Weaver alluded to the 'buses and parcels-carts that are driven by means of a secondary battery, and seemed to think that secondary batteries might possibly take the place of horses in dust-carts. We have no great faith in progress in that direction, but if the mind of the electrical engineer is allowed full play it is easy to see how great a share electricity may play in many necessary municipal operations. Assume that electric lighting becomes general. There will then at every house or every lamppost be terminals that are within easy reach for whatever service may be required. For the moment restrict the outlook to dust-carts and drain gullies. There is little difficulty in designing a cart to be driven by a motor, the motor also being able to be used for other purposes, such as winding a drum connected to a pulley. Imagine, then, the household refuse collected in a pattern receptacle, and placed in certain well-defined positions ready for the collector. The collecting cart could be driven by a motor obtaining current from street lamp terminals or other terminals suitably placed. When it was necessary to lift the refuse the cart would be standing still, and the pulley could be attached to the motor, the refuse lifted as high as required and tipped into the cart. The pulley would be switched off and the cart be switched on, and so on through the whole round. If an electric tram line existed, the work would be still further simplified, especially where overhead wires could be tolerated. Admit that the idea is merely a stretch of the imagination, at the same time it must be admitted that it is perfectly feasible, and that the simplification of details would make it commercially practicable. A reel with a hundred yards or so of flexible armoured wire, with plugs to make contacts at the lamppost or other terminals, and with the motor brushes, would be no very weighty apparatus, and would run the cart from lamppost to lamppost, even when more than the average distance apart. As for the street gullies, it is advisable not to let the solid detritus from the streets get into the drains, and so traps are used to contain the solids, while the water itself runs over into the drain. Mr. Bennett, the engineer to the Southampton Corporation, has devised gully traps to be raised by hydraulic pressure, or by compressed air. We have seen the arrangement and know how admirably it can be made to work and what a great saving is effected

thereby, but it seemed to us that the properly-designed cart with its motor and pulley could lift the trap just as well as the water or the compressed air, and with electricity generally in use would probably be a much less costly process than either the hydraulic or compressed air. Thus, while we agree with Mr. Weaver that there is nothing outrageous in his idea—even though he might not have put forward that idea seriously, but rather as a means of turning the laugh against the advocates of the inexhaustible mine of steam development to be got from destructor work—we do not go with him in the use of secondary batteries, but prefer to "dip into the future" and foresee the development of the motor. We take it that, though speaking jocularly, Mr. Weaver had serious thoughts behind, for the remarks arose during the discussion on a paper by Mr. Jones, of Ealing, upon refuse destructors. The reader of the paper, and the various speakers, seemed to think that properly-constructed destructors in most districts would enable the authorities to obtain sufficient heat to generate a considerable quantity of steam, and that this steam might be used in a variety of ways—among others, to drive engines and dynamos. Indeed, in various towns electric light is even now so obtained, as at Southampton, where Mr. Bennett has a considerable installation. Further, if, as Mr. Mawbey, of Leicester, says, a greater quantity of heat can be obtained by the use of movable bars and other modifications, this excess of heat may lead to more steam being available, till Prof. G. Forbes's anticipation is realised, and the refuse of a household is found sufficient to generate the artificial light it requires.

THE SEARCH-LIGHT AND NIGHT FIGHTING.

When the arc lamp and the dynamo became practical, a modification of the former was soon introduced as a search-light for naval purposes. Now all ships of war and most of the large vessels of commerce are fitted both with search-lights and with electric light generally. The field telegraph is an important auxiliary in all land operations, and now experiments are being inaugurated to obtain information as to the value of movable search-lights for night attack, for the use of fixed search-lights is not so new. The successful use of movable search-lights for military purposes is no easy task, but no doubt in many instances will amply repay all trouble. It has been left for Lieut.-Colonel Tully, 4th V.B. East Surrey Regiment, in conjunction with Captain Ronald Scott, 4th Middlesex Rifles, to attempt experiments in night attack and defence aided by search-lights. Captain Ronald Scott, whose experience with search-lights is very extensive, supplied the electrical equipment, using accumulators to work the search-lights rather than a dynamo. This seems the correct plan, because the object is to remain hidden whilst the enemy is exposed. A dynamo means a portable engine, but the accumulators mean nothing more than waggons and horses. It is impossible for us to enter into the details of the sham fight which was carried out on Wimbledon Common, but it is absolutely certain that valuable experience in the use of the search-light was gained. At first, instead of showing the enemy and hiding themselves, the use of the light produced the contrary effect, but Captain Scott, grasping the situation, took the management of the light into his own hands, and thenceforth obtained the effect desired, with the result thus described in the *Daily Graphic*: "When the foe did appear, therefore, they were ready to meet him with effective volleys, which seemed to leap out suddenly from the wall of night; and directly the attacking skirmishers halted, the search-light began to play a dazzling ripple along their line from end to end, now flashing in one man's eyes and then in another's, so that not only were they seen clearly from our side, but their aim must have been baffled completely. When they began to advance again the light was flashed in their eyes again, so that had there been irregularities of ground marching without mishaps would have been impossible." We have no doubt this successful experiment will lead to a more extended series, so that the correct use and true value of such a movable light for night operations may be determined.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

HISTORY OF LIGHT AND POWER.

SIR,—I feel sure your numerous readers cannot fail to read with pleasure any historical work or comments which may bring to light the evolution of electrical engineering and the historical work of ancient electricians, but as all such works to be of real value to future generations should be based upon solid and indisputable facts relating to the matters in question, under these circumstances I feel sure Mr. Arthur F. Guy will forgive me calling attention to one or two errors which have crept into his articles. First, Mr. Guy fixes the adventual year of the evolution of electric lighting as 1810. Now, I think I am right in suggesting that this should be fixed as the year 1809 instead of 1810, especially as the first practical experiments relating to the production of electric light were carried out, not by Sir Humphrey Davy himself, but by Dr. Wollaston, Sir E. Horne, and Mr. Children, the designer of the Cruikshank-Children battery, as used for the experimental work carried out at the Royal Institution, in conjunction with Prof. Brande, the secretary of the above institution. Sir Humphrey, 'tis quite true, greatly improved upon the earlier experiments of the above in the year 1810 by using a battery of greater intensity and by adopting charcoal rods enclosed in an exhausted globe filled with chlorine gas. Hence more brilliant effects were obtained by him than from the experiments of earlier workers, many of whom, both in England and abroad, were working upon various methods for the production of the new light, and whose names should not be allowed to be buried in oblivion; hence my object in calling attention to some of the work carried out at the early part of the present century, and also prior to Sir Humphrey Davy. I may say I have no desire to underrate the grand work of Sir Humphrey, but simply to bring to light the work of his associates, and other inventors at this early period, who were all deeply absorbed in solving the long-looked-for problem—viz., "the production of electric light"—many of whom deserve great credit for the various contributions and experiments brought to light by them between the years 1803 and 1810. Amongst them I think should be coupled the name of Ritter, whose early and successful experiments on battery work and the storage of electricity is, perhaps, one of the most interesting

in these modern times. His early work is clearly described in Izarus's "Manual de Galvansme," and other French journals published between the years 1803 and 1806. Ritter was apparently one of the foremost electricians of his time, and I have no hesitation in saying, according to Izarus's descriptions of Ritter's work, that to this savant the credit is due of having constructed the first secondary battery known to science, and whose early work and experiments on storage and polarisation batteries gave Nobile, Brugnaletti, Zamboni, Becquerel, Marianini, Joule, De la Rive, Planté, Kirchhof, Niaudet, and other early workers of the more ancient school, also the work of more recent inventors, such as Percival, Faure, Woodward, Brush, Swan, and others belonging to the modern school, whose combined improvements have resulted in reliable batteries; but at the same time, the fundamental and ground work upon which the secondary battery industry has been immortalised certainly descended from the fundamental principles and pioneer work carried out by Ritter, and to him the credit of this invention should be awarded. Moreover, I fail to see how Sir Humphrey Davy could have used a "Grove battery," as suggested by Mr Guy, which battery, if my memory serves me rightly, was not invented until about the year 1839. Probably the battery used by Sir Humphrey would either be a Ritter, Cruikshank Children, or Wilkinson type, as these were the only suitable batteries then known to science and in use at the early part of the present century. In order to make his work of real value I should advise Mr Guy to correct it prior to publication, for as all rights are reserved, I presume this is the intention of the compiler of the articles, which have been read with interest by yours, etc.,

ARTHUR SHIPPEY.

Sept. 15, 1892.

MAGNETIC VISCOSITY.

BY J. HOPKINSON, F.R.S., AND B. HOPKINSON.

The experiments herein described were made in the Siemens Laboratory at King's College. The object was to ascertain whether the cyclical change in the magnetic induction in iron due to a given cyclical change in the magnetising force is independent of the speed at which the change is effected—that is, whether any sign of "magnetic viscosity" or "magnetic lag" can be observed when the rate of change is such as is found in transformers. The question is one of much practical interest, and has been much discussed, amongst others, by Prof. Ewing at the recent meeting of the British Association. Prof. Ewing has devised apparatus adapted to deal with this matter as well as for drawing curves of magnetisation.

We have experimented on two materials. One was soft iron and the other a hard steel containing about 0.6 per cent. of carbon. Both samples were supplied by Messrs. Richard Johnson.

It had been found, in experiments on ordinary transformers, that the local currents in the iron made it impossible to form a correct estimate of the magnetising force. The effect of such local currents can, of course, be diminished by using finer wire or plates and better insulation. Our material was in the form of wire $\frac{1}{100}$in. diameter, and the wire was varnished with shellac to ensure insulation. It was wound into a ring having a sectional area of 1.04 square centimetres in the case of soft iron, and 1.08 square centimetres in the case of hard steel, and about nine centimetres in diameter. The ring was wound with about 200 turns of copper wire, and with a fine wire for use with the ballistic galvanometer. An inspection of the curves showing the results will satisfy the reader that the effects of local currents were negligible.

For determining the points on the closed curve of magnetisation, given by rapid reversals of the current in the coil, the ring was connected in series with a non-inductive resistance to the poles of an alternate-current generator or a transformer excited by the generator (see preceding column), in which A B are the poles of the transformer or generator, C D the terminals of the non-inductive resistance R, H the coil surrounding the ring, P and Q the studs of a reversing

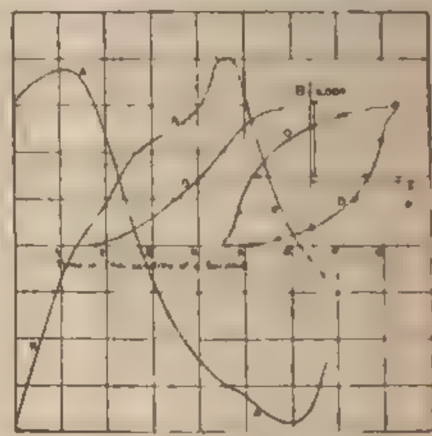

FIG. 1.—Soft Iron. Frequency 103.

key connected to the quadrant of a Thomson quadrant electrometer, L a key, by means of which Q could be connected with C or E at will, and K a revolving contact maker through which P was connected to D. A condenser was connected to P and Q in order to steady the electrometer readings. The contact maker, K, was bolted on to

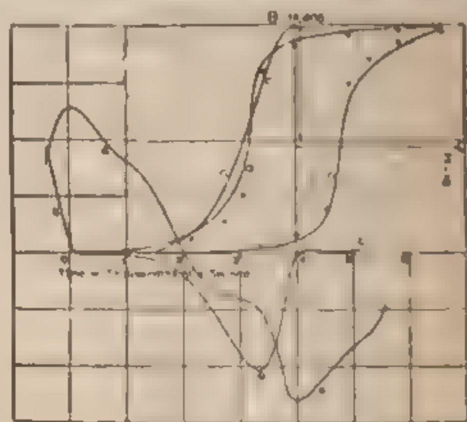

FIG. 2.—Soft Iron.

the axle of the generator. It consists of a circular disc of ebonite, about 13in. in diameter, having a small slip of copper about $\frac{3}{16}$in. wide let into its circumference. A small steel brush presses on the circumference and makes contact with the piece of copper once in every revolution. The position of the brush can be read

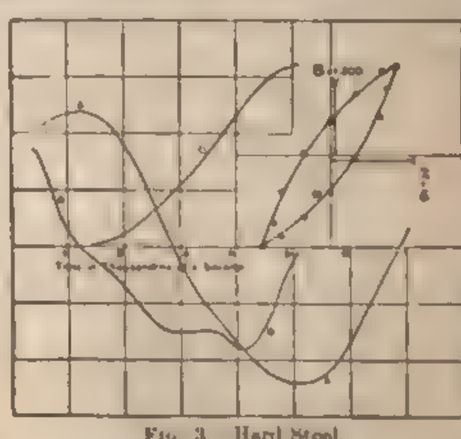

FIG. 3. Hard Steel.

off on a graduated circle, and thus contact can be made at any desired instant in the revolution, and that instant determined by means of the graduated circle. The quadrant electrometer thus gives the instantaneous value of the difference of potential between the points C and D, or the points D and E, according to the direction of the

key L. The frequency was in all cases, except one, 125 complete periods per second. From observations of the values of the potential difference between C and D at different times in the period, a curve (A) was plotted giving the current or magnetising force in terms of the time; a similar curve (B) was plotted for the E.M.F. between D and E. The curve (B) corrected by subtracting

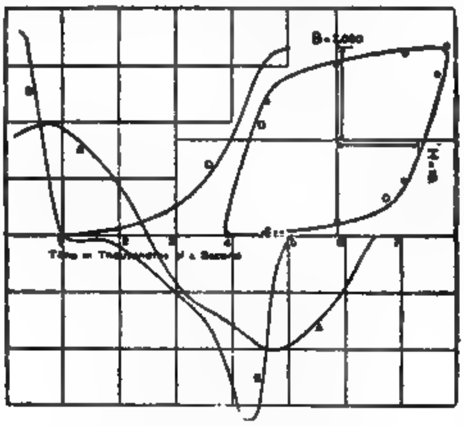

FIG. 4.—Hard Steel.

the E.M.F. due to the resistance of the coil H gives the potential or time rate of variation of the induction in terms of the time. Hence the area of B up to any point plus a constant, is proportional to the induction corresponding to that point. This is shown in curve C, which is the

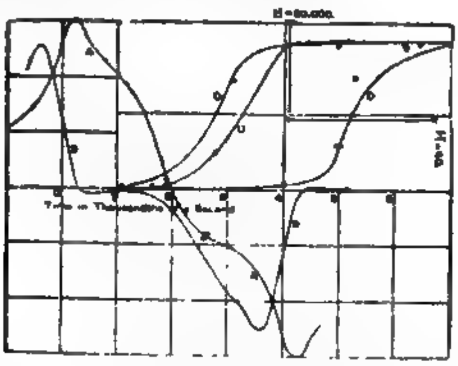

FIG. 5.—Hard Steel.

integral of B. A fourth curve (D) was then plotted, in which the abscissa of any point is proportional to the magnetising force at any time (got from curve A), and the ordinate is proportional to the induction at the same time (got from curve C).

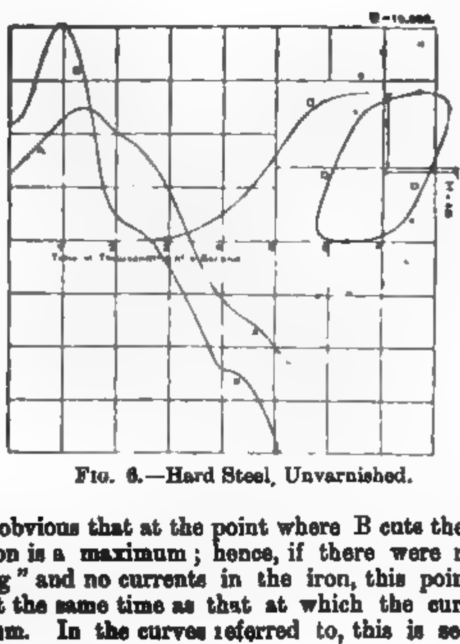

FIG. 6.—Hard Steel, Unvarnished.

It is obvious that at the point where B cuts the axis the induction is a maximum; hence, if there were no "magnetic lag" and no currents in the iron, this point should occur at the same time as that at which the current is a maximum. In the curves referred to, this is seen to be nearly the case.

The slow cycles were obtained from the ballistic galvanometer, by observing the throw due to a known sudden change in the magnetic force. Care was taken always to take the material through the same cycle. The points got by the slow method are in each case shown in absolute measure on the same scale as that to which the quick curves are drawn, and are indicated by black dots; they are hardly numerous enough to draw a curve with certainty, but are ample to exhibit the identity of or the character of the difference, if any, between the curves, as determined by the two methods.

Figs. 1 and 2 show the results of experiments on soft iron, Figs. 3, 4, and 5 were obtained from the hard steel. In all these the agreement between the slow and rapid cycles is fairly close. Fig. 6 is interesting, as showing the large effect of local currents. It was obtained from the same sample of steel wire as Figs. 3, 4, and 5, but the wire was not varnished. It will be seen that the maximum induction lags behind the maximum magnetising force about one-sixth of a complete period, and also that the maximum induction attained is but 10,000 as against 17,200 obtained from the same (apparent) magnetising force by the slow method.

Hence the general result is that up to the frequency tried—*i.e.*, about 125 per second—there is no sign of magnetic viscosity; the magnetic cycle is unaffected by the frequency so far as the maximum induction for a given magnetising force is concerned, but that there is a sensible difference between the curve as determined by the two methods, most apparent in that part of the curve preceding the maximum induction. This difference is well shown in Fig. 5. We have not yet fully investigated this feature; possibly it arises from something peculiar to experiments with the ballistic galvanometer.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES.

LECTURE I.

(Continued from page 268.)

The Northampton Electric Light and Power Company have equal weights of distributing mains and feeders. The capital invested in mains is 42 per cent. of the total capital of the company, the length of mains 2,800 yards, including 350 yards of feeders only, and the total weight of copper 16 tons. The mains consist of bare copper in Crompton culverts, where possible; Henley's A A cable in 2in. iron pipes at road crossings, etc.; Fowler-Waring cables, lead-covered, laid in half glazed-pipes with sand, and covered with concrete, and Callender cables in iron troughs and bitumen, for isolated feeders. The average cost of mains is 45s. per yard. The indicated horse-power at work is 240; 120 additional being on order. The number of 8-c.p. lamps supplied, 33,000. The proportionate cost of buildings and machinery, etc., to paid-up capital is—building and machinery, 46 per cent.; land, 5 per cent.; the paid-up capital being £15,000.

Another company, with paid-up shares and debentures = £73,585, whose expediture on mains is £17,440, has 20 miles of cable in six miles of streets, consisting of 20½ tons of copper for feeders, and 28 for distributing mains. Actual cost of supplying and laying Callender-Webber casing with three 2in. ways, including all charges, with straightforward work = 6s. 6d. per yard, or including the draw and service-boxes, 8s. 9d. per yard run. The lamps = 28,000 of 8 c.p., and there is 830 h.p. in the central station in the shape of steam engines alone.

The Allgemeine Elektricitäts Gesellschaft has over 700,000 metres of copper, weighing 1,500 tons, nearly all in Siemens armoured cable, costing from £2 to £4. 10s. per yard. This enormous mass of copper accounts for the splendidly constant pressure always maintained in the network.

The Secteur Clichy, in Paris, cover 26 kilometres of street with 31 kilometres of feeders and 121 of distributing mains.

* Cantor Lectures delivered before the Society of Arts.

The cost of laying 3in. iron pipes in cement in New York, with manholes 7ft. deep, 8½ft. square inside, with 12in. walls of brick in cement, depends on the number of ducts, and is as follows

No. of ducts.	Dollars per duct per foot run.	Shillings per yard.

The average cost of a house connection, from a large number of actual cases is 66·02dol., say £13.

These special cases are given as a small contribution to the general question. My own general experience is that mains ought to cost, on the low tension system, about half the capital of the company, about equally divided in distributing mains and feeders. I think that far more copper would be put down in mains if people realised the low rate of interest at which money could be raised in debentures on them.

Experience is the best guide as to the proportion between feeders and network mains. The smaller the latter, the more numerous must the former be. The distance that can be covered by a feeder depends on many things, but firstly on the variation in pressure allowed at the house connections. The Board of Trade, wisely I think, has given great latitude, four volts either above or below the normal 100 volts—*i.e.*, an 8 per cent. variation—but it is to be hoped that supply companies will find it to their interest to attain a higher standard. If the feeder point is kept at a constant pressure of 100 volts, the four volts will be lost in 80 yards if the section of copper is based upon a current density of 1,000 amperes per square inch, or in 240 yards if 330 amperes per square inch is chosen; and I am glad to say that in this country a large section like this is recognised as the best design. If now we use a three-wire system, we can go to twice the distance—or 480 yards—with a current density of 330, still with a maximum drop of four volts. If the pilot wires which indicate pressure be not at each feeding point, but half-way to the most distant lamps supplied by a feeder, the length of main which can be fed is again twice as great, or 960 yards, the lamps at the feeding points varying from 100 volts at times of small demand, to 104 at the maximum, the lamps at the distant end varying from 100 volts at times of small demand, to 96 at the maximum. If now the lamps at the feeding points be 104-volt lamps, and those at the distant end 96-volt lamps, with graduated voltages at intermediate points, we can increase the length of main supplied by a feeder to 1,920 yards, and no lamp will have a greater variation than four volts above or below its normal value. Of course, this result has never been attained in practice, because in most cases it is difficult to accomplish. I do not generally approve of using lamps of different voltage on a circuit. The only time I ever sanctioned it was when I settled what was to be done by the St. James's and Pall-mall Company. Here the district was so compact that I could see easily that we would not be bothered by the future extensions. There is also some trouble in putting the pilot wires in the place indicated. There is also some difficulty in arranging the feeders so that they all feed into the network at the required pressure. Some engineers are also afraid of the three wire system, having had no experience of its use. And, again, in a badly-fitted station, it is difficult to ensure that the engines are working quite uniformly, so that a 2 per cent. variation, up and down, may be all that can be calculated for in order to conform with the Board of Trade requirements. All these reasons may reduce the workable distance, even when the low-current density here assumed is taken, from the above 1,920 yards down to 240 yards. I wish to impress strongly on you the fact that there are four distinct methods of improving the distribution—(1) increasing the regularity of the engines, (2) using the three-wire system, (3) putting the pilot-wire connections halfway between feeder points, and (4) varying the voltage of lamps according to the distance from a feeder point. The last is the only one which cannot be safely done in all cases, and each of these four remedies enables us to go to double the distance, the introduction of the three-wires being the only one which increases the weight of copper a little; or we may say, especially with relation to the position of the pilot wires and the voltage of lamps, that these remedies each halve the weight and cost of copper in the mains, and, combined, reduce it to one-quarter. The practical objection to using lamps of different voltages is that generally the network is first laid down and the feeders added in greater number as the demand increases, hence the voltage of lamps in any house will be changed. But the improvement on existing methods which I have advocated, of putting the pilot wire attachment half way between feeder points, saves half the copper, and can always be applied.

Management of Feeders.

In the central station the arrangements for supplying the feeding points with the same pressure are not always satisfactory. It has been customary in many cases to make the resistance of each feeder the same, so that when the same current is flowing in each the fall of pressure along the feeder is the same. Other people use adjustable resistances to regulate the pressure. In both these cases omnibus bars can be used to connect all the dynamos in parallel and all the feeders in parallel. This is very wasteful. Another plan is to use the dynamos at different pressures, and group the feeders on them according to their requirements. This is perfect in theory, but difficult in practice. It involves frequent shifting of a feeder from one dynamo to another, and it involves engines running at low loads. Another plan has been suggested, to put in a few secondary battery cells in the feeders in place of resistances, some to raise and others to lower the pressure according as they assist or oppose the current. The two volts given by such cells is a convenient unit for such a purpose. The best plan seems to me to be one which has not hitherto been adopted. Connect all the dynamos in parallel on omnibus bars. Between this and the feeders put switches, by means of which one or more low tension dynamos (of two volts, say) can be switched in to assist or oppose the current. I would not suggest this were I not now thoroughly satisfied with the low tension non commutating dynamos with which my name has been connected. To show their suitability, I will merely record an experiment with one of these dynamos used with a Parsons steam turbine. The armature was merely a solid bar of wrought iron, 3in. in diameter, and it rotated between two magnet poles, which enclosed it, at a speed of 24,000 revolutions a minute. With this we welded pieces of iron ⅝in. diameter, and then heated a rod of ⅛in. iron, 15in. long, to a white heat for an hour and a half, and everything was working quite smoothly, and could have gone on like that for 24 hours. The E.M.F. on open circuit was four volts, and on closed circuit two volts.

Loss in House Wiring.

I hope that before long the Board of Trade will reduce the variation now allowed of 4 per cent. up and down to half this amount. There is always a certain loss of pressure in the house wiring, which ought never to exceed two volts. But as householders seldom engage an electrical engineer to protect their interests against the contractors, the latter generally use thinner wires than is right, and so reduce the pressure in the lamps still more. A variation of more than 2 per cent. from the normal pressure at the lamps is very objectionable in practice, though I suppose we must put up with it for some time.

Recording Voltmeters.

I will now show you some results of actual work. I have on the table one of the recording voltmeters made by Messrs. Richard Frères. It is like the well known recording aneroids. A cylinder is revolved by clockwork and carries a ruled sheet of paper, while the paper travels horizontally, a voltmeter causes a pointer filled with ink, and just touching the paper, to rise and fall with the electric

pressure, and thus we get a continuous record of the pressure which a house is receiving from the supply company. This instrument is very convenient and useful. The one I have been using is made to work up to 120 volts, and its range of greatest accuracy is at half this pressure. The controlling force of the magnet is weak at 100 volts, and the friction of the paper comes into play to diminish the actual irregularities. Still, I have been able to obtain

FIG. 2.

interesting curves in a variety of places, and I wish to draw the attention of administrative bodies like the London County Council to the necessity of using such instruments in the interests of the community, and as the only real check upon the supply companies. The instrument which I have used reads low at 100 volts. I have a number of curves taken at four places on the mains of one supply company, and except at one place they come out very nicely, only we must remember that the full irregularities

FIG. 3.

are not shown by this instrument. The places of which records are shown are my office, at 34, Great George-street, 39, Victoria-street, 13, Ashley-gardens, and the Scottish Club in Dover-street, Piccadilly. (Some of these curves are here reproduced. Figs. 2 and 3 are records taken at my office in Great George-street; Fig. 4, one taken at the Scottish Club; and Fig. 5, one from Ashley-gardens.) To show the real irregularities, I have added drawings from actual observations at frequent intervals of an accurate

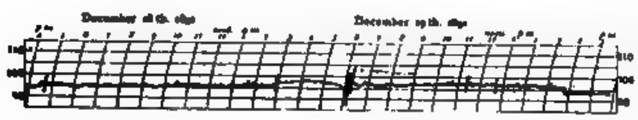

FIG. 4.

voltmeter, when you see, Fig. 6, that the pressure in my office is always high, and sometimes reaches 109 instead of 100 volts. Of course this is very destructive to the lamps, and renders the company liable to fine. The pressure at this part of the distribution system is always too high, and apt to injure the lamps. At Dover-street, on the other hand, the pressure is always too low, and the illumination is bad. When the busy evening hours come on, the pressure at Dover-street always falls. The influence of a

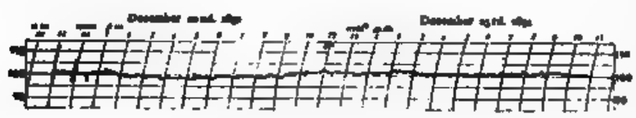

FIG. 5.

fog is shown in the same way. It is not to the interest of a supply company that such defects should go on. While exhibiting these curves, I had one taken at the Athenæum Club, Fig. 7, which is supplied by a gas engine and dynamo of its own, with accumulators as regulators, and for use during slack hours. Notice the violent irregularities, simply owing to the carelessness of the attendant, and also notice the effect of the pulsations of the gas engine, showing a pulsation of two or three volts, which goes on every second or half second, and is most trying to the eyes.

FIVE-WIRE SYSTEM.

The evident advantages of the three-wire system can obviously be extended to a greater number of wires, if we do not object to bringing the higher electric pressure into our houses and up to the lamps. This has been done with five wires, by the company lighting the Secteur Clichy at Paris, and in other places. Since five wires here take the place of eight, the advantage is greater than when three wires take the place of four. By using it we can also go to twice the distance of the three-wire system. I shall have something to say about this method in my next lecture, to which it is more suitable.

BATTERIES.

I must conclude this part of my subject with some mention of a class of electrical apparatus which has been improved more than anything else in connection with low-

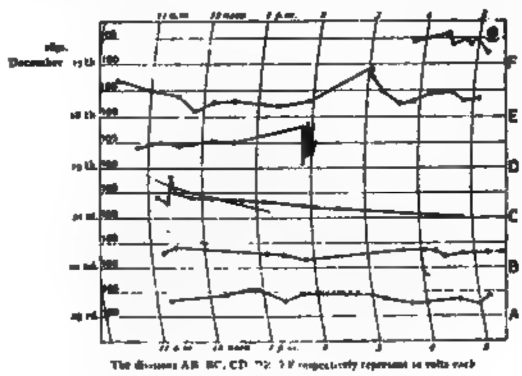

FIG. 6.

pressure supply since I gave my previous Cantor lectures. The position which I then took up was this, that there was no plan for electric lighting so satisfactory as the secondary battery plan, but it was hopeless to think of it until one important element was invented—namely, a practical secondary battery. That *desideratum* is much nearer realisation. In the last 10 years dynamos have been much improved, and so have lamps, but in no branch has the improvement equalled that in secondary batteries.

These improvements are partly in the way of making the plates more substantial, and less liable to buckle or scale, or for the pellets to drop out, and partly in their management, the chief step in the latter direction coming from the discovery that batteries will stand any amount of overcharging, and really improve in the process, and also that they should never be allowed to run down, and that low specific gravity should be remedied by persistent overcharging, recourse to adding acid being only resorted to at rare intervals. To keep batteries in a high state of preservation in this way involves great expense from the

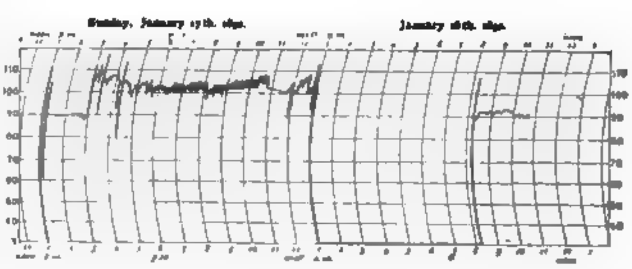

FIG. 7.

frequent overcharging, and also from the fact that, if we never take much out of the battery, we must have a larger outlay in them to do our work. At the present time the only objection to batteries is their expense, and that is now far less serious than six years ago, when their life was very short. Secondary batteries are often called accumulators, or storage batteries, according to the purpose for which they are wanted. They are used for five different purposes: (1) As regulators; (2) to replace dynamos, and give workmen a rest at idle hours; (3) to add to the total output of a central station at a time of maximum demand; (4) as a reserve in case of breakdown; and (5) to transform down from high pressure in the streets to low pressure in the houses. All these are most useful purposes,

and seem so desirable that many companies have adopted them even at a greater cost of supplying the electricity.

Of course, you will always find the manufacturers of any such special plant saying that it does not increase the cost to use it, and when, as often happens, the manufacturer acts also as consulting engineer, you may expect the use of such plant to be more extensive than their costliness warrants. This has been the case in England in many cases, but it is not to be regretted by the general public, because these cases have given us much valuable experience. In this year, 1892, however, the improvements in storage batteries are such that it hardly costs anything more to use them than to do without them, and we see the desirability for storage of some kind in our central stations so much in actual working, that we may hope the time will soon come when some kind of storage will be possible for a large part of our generating plant, so that we will not require to fire up a lot of boilers just for a few hours' work. When a battery is put across the mains at the central station it acts as a regulator, and keeps the current steady in spite of irregularities in the engine. This ought not to be an important point in central stations, but it is in isolated plant worked by a gas engine. The battery in the central station, however, offers a splendid means of regulating the pressure in the feeders, which can then be supplied at any pressure with current, and the size of copper can then be chosen to fulfil the economical law of being proportioned to the current, and not to the barbarous law of making the resistance of all feeders equal. Much discussion has arisen about the value of accumulators in central stations, but it is remarkable that, up to the present time, the one great advantage has been overlooked, which is that you can use them in shunt on the mains as a means of regulating the pressure supplied to feeders. This action is the only solution that has been tried which gives perfect satisfaction. I do not believe that the introduction of accumulators into a central station has ever introduced economy, but in many ways it leads to a better service, and in no way more than in this which I have just indicated. So much is this the case that, except in the few cases where economy overrides quality of light, or in some cases where a fall of water is the source of power, I do not think that any low tension continuous-current central station on a large scale is complete without a small supply of accumulators. The other use of accumulators as transformers of high pressure into low pressure belongs to the subject of my next lecture.

LECTURE II.

In my last lecture I urged the importance of not slurring over the actual difficulties that are before us. We are looking at the question of distribution from an engineering point of view, and it is desirable always to face the difficulties and see our way as far as possible, rather than to slur them over and pretend that they do not exist. Now, I pointed out the chief causes of excessive expenditure in electrical distribution through towns. They are two—first, the cost of distribution; second, the cost of generation. In both of these cases of production and distribution the expense is greater than it would be if we were producing it for our own purpose at a constant rate. Distribution is particularly expensive at the present moment, because there is only a small number of houses connected. Mains are being laid through great lengths of street, and perhaps only one in 30 houses is taking current. That will mend as time goes on, and that cause of excessive cost will diminish in consequence. The other great source of expenditure that any supply company has to face lies in the fact that electricity is not wanted uniformly throughout the 24 hours. This is, perhaps, the most important point to which attention has been drawn of late years in the question of distribution. It injures us in two distinct ways—first, through our engines; secondly, through our boilers.

Owing to the fluctuating demand for light, we are compelled to vary the number of engines which are working to supply the mains, and employ the engines sometimes at below their economical load, and that is extravagant. Besides this, the boilers consume more fuel than if a continuous supply is given, because so much coal is spent in heating them up in the evening. With regard to light loads of engines, few people realise what enormous loss there is when we are running powerful engines at light loads, more especially compound engines. It is quite possible that a 100 h.p. engine, which would be consuming, say, 22lb. of water or steam per indicated horse-power per hour when running at full load would, running at light load—1 h.p. or 2 h.p.—be consuming as much as 600lb. of steam per horse-power hour. This great source of loss could be got over by having the units in the way of engines tolerably small. The smallest size of engine is efficient, so that by employing a number of them, and putting them on in turn, we never have much loss through under loading; but with respect to boilers, we are without remedy at the present time. Great attention was drawn to this point in the paper read by Mr. Crompton before the Institution of Civil Engineers last year, in which he introduced the term "load factor." Load factor is a very important thing, but the one peculiar thing about it is that no one knows what it is. Mr. Crompton introduced five distinct definitions of the load factor, each of them giving a totally different meaning to the other cases where the words are used without alluding to what is meant. I will give you a series of definitions, which, I trust, will suffice for the future. I had hoped that Mr. Crompton would have given us an exact definition, but he has failed us in that, and, therefore, I will give you what I think will be sufficient for engineers.

I will draw attention to these diagrams which belong to the Berlin station.* The heavy load lasts only for a few hours. The thick white line indicates the load which is passing out. During the winter months, at about six or eight in the morning, a small peak is shown. There is nothing else till the afternoon, when it rises to its maximum. The same general features prevail throughout the year in the different months, except in the mornings of the summer months, when the demand for current ceases, and in the summer months the height of the peak diminishes, and the number of hours. Similar curves have been taken in many other central stations, and I would refer to a similar set of great value relating to the St. James's and Pall Mall Company's station, which show the same general fluctuations as the Berlin curves. There are two consequences to be noted from this great irregularity in the demand. In the first place, owing to the high peak that we have during winter, we must have a large amount of machinery ready to take part in supplying current; in the summer months a great part is not in use; and during the day, even in winter, a great portion of our machinery is absolutely idle. It is in this way idle for the greater part of the year. In the second place, we have to fire up our boilers during the slack hours, just before the rise, so as to be able to cope with the demand at the busiest hours, which means waste.

That being the general state of things, let us come to actual definitions about "load factors." Mr. Crompton tried to indicate that it was the ratio of the average quantity of electricity to the maximum, but what maximum was to be chosen for the whole year was not defined. I propose to adopt three distinct definitions—the machinery load factor, the current load factor, and the temporary load factor. By the machinery load factor for any period, I mean the ratio of the average current during that period to the maximum current obtainable from the machinery. By the current load factor for any period, I mean the ratio of the average current during that period to the maximum current ever supplied from the station; and by the temporary load factor for any period, I mean the ratio of the average current during that period to the maximum current supplied during that period. If we adopt these three I think they will be sufficient for all our purposes.

(To be continued.)

* These diagrams are published in a paper read by Prof. George Forbes before the Institution of Electrical Engineers, 28th February, 1889, on "Some Electric Lighting Central Stations in Europe, and their Lessons."

MOTORS USED FOR FOG SIGNALS IN THE NORTHERN LIGHTHOUSE SERVICE.*

BY MR. D. A. STEVENSON, M.I.C.E.

The author dwelt upon the necessity of a means of signalling on the coast line during foggy weather, and enforced his statement by details as to the duration of fog in this country. It appeared that the number of hours in Scotland is 395 per annum. The most powerful sound signal in use is the siren, actuated by compressed air. The author described the various motors used for the purpose. The sources of power are motion of the sea by waves and tide, manual labour, clockwork, steam, hot air, gas, and oil engines. After discussing these various methods, the author sums up by expressing his opinion that the best motor for fog signal purposes yet tried is undoubtedly the oil engine. Mr. Stevenson, however, points out that the best sound signals are feeble and unreliable, and it is his opinion that the solution of the problem of warning vessels in times of fog will be found in the method proposed by Mr. C. A. Stevenson, in which an electric cable or conductor is laid down off a coast or dangerous place. This would act on an instrument attached to each vessel, and so give warning of the approach to danger.

The discussion on this paper was opened by Mr. JEREMIAH HEAD, who pointed out the great advantage of the petroleum engine for fog signalling purposes in isolated spots, such as those upon which the installation was usually required. The smaller weight of the material used, compared to the coal and water of the steam engine, and the quickness with which the motor could be started, were dwelt upon by the speaker.

Colonel CUNNINGHAM pointed out that in many lightships there was no sound signal other than a bell. He considered it desirable to introduce an automatic arrangement of some description. He asked the maximum duration of any fog.

Mr. SENNETT said the paper was of particular interest to him, as mention had been made of the probability of some system of electric cable protection being perfected by means of which vessels could be warned of their approach to the land during fog. He had devised a scheme for this purpose and had just commenced experiments. His system was to produce a sound of known pitch beneath instead of above the water; for this purpose an ordinary siren worked by compressed air, and having independent motion imparted to it, so that it would emit a note of constant pitch, would be suitable. On board the vessel he would arrange an electrical receiving instrument, consisting of a micro-telephonic apparatus tuned in unison with the sound of the warning station. This instrument would be located in a padded cabin, and the officer would listen for the code signal which would give him the name of the station from which the sound emanated. This direction in relation to the course of the ship could be read off by a suitable dial. Mr. Sennett pointed out the great danger in the present system of aerial fog signalling. This was caused by the existence of what Prof Tyndall had termed acoustic clouds, which are in reality strata of air of various temperatures which had the power of refracting the acoustic ray, tilting it upward so that it failed to reach the vessel. Thus, with apparently the same atmospheric conditions, a fog signal which had been heard at one hour of the day at a distance of 10 or 15 miles might not be heard at another hour more than 3 or 5 miles. Mr. Sennett pointed out the fact that the velocity of sound in water was some five times as great as in air, and that the disturbing conditions above mentioned did not exist in the sea. With reference to the communication with lightships, the speaker had devised a system in which the signals were given entirely by induction, so that no material or cable connection between ship and shore was necessary. He had only the River Thames to experiment in, and he would be glad to hear of Mr. Stevenson following the matter up, as he had better facilities for working in the same direction.

Mr DAVID CUNNINGHAM, the Dundee Harbour engineer, said the great advantage of the petroleum engine was that the sound was got directly the fog came on, without waiting to get up steam. They could hear a fog signal for 10 miles under favourable conditions, but the sound was not to be always depended upon for more than a half to a quarter that distance. He had known one case in which a steam yacht had started from the harbour when the siren was in operation, but at the distance of half a mile it could not be heard, although when four miles had been traversed, the sound was again audible.

Mr. WIGHAM said that however good the signals described might be, it was no good for mechanical engineers turning their attention to the matter unless they were adopted. It seemed to him that when a reasonable demand was made by the shipowner to have a danger signal put up, that demand should be attended to, and not refused on the paltry ground of want of money. Two years ago the "City of New York" was within a yard or two of the very rock on which the "City of Chicago" had been recently wrecked. The sudden clearing up of the fog had revealed the danger. At that time the shipowners memorialised for a light to be put on the Old Head of Kinsale, but the request had been refused on the ground of the expense. The speaker considered the gas engine superior to the petroleum engine when gas could be got; in other cases the petroleum engine was best.

Mr. PERRY F. NURSEY gave some very interesting results of his experience with submarine explosions, as bearing upon the conveyance of sound by water.

Mr SENNETT added that Prof Hughes had made experiments in Lake Geneva. An ordinary bell was rung under water, and the sound could be heard a distance of nine miles by the aid of a small speaking tube to convey the sound from the water to the listener's ear. While bathing two stones were knocked together, and at a distance of half a mile the noise was so unpleasant when the head was put under water that the experiment was not repeated.

Mr. C A. STEVENSON, in replying to the discussion for his brother, who was prevented from being present by illness, said that the cost of a first-class installation, such as he had described, was £1,700. The maximum duration of any fog in that district was 80 hours. With regard to the under-water signalling he did not think that the indications would extend for five miles. In the case of a dynamite explosion under water it was not audible at very short distances, whilst it was well known that divers could not hear the firing of guns. It may be pointed out that neither of these cases are analogous to that quoted by Mr. Sennett.

* Paper read before the British Association at Edinburgh.

PRIMARY AND SECONDARY CELLS IN WHICH THE ELECTROLYTE IS A GAS.*

BY PROF. SCHUSTER.

It is well known when you have a discharge passing through a tube the tube thereby becomes a conductor, and you can send a current in any other part of the tube from a Daniell or any other cell through. It seemed to the author that it would be of interest to study the laws of that conduction which he would like to call secondary conduction in gases, because we are evidently having a more simple phenomena than in the other. For this purpose I have a tube with electrodes, then in some other part of the tube there is introduced platinum wires which are connected to ordinary batteries. While refraining from entering into the principles of the laws of secondary discharge, there is one point which is of interest on the theory started by different physicists, that the primary phenomena of discharge depends upon the dissociation of molecules, we have never yet found effects of polarisation similar to that when water is being decomposed in gases. Attempts have been made to explain why such phenomena could not happen in gases. We have looked very carefully for that phenomena of polarisation in this secondary conduction. When we got hydrogen in the tube there was no trace of polarisation with aqueous vapour or hydrochloric acid, or with a number of combined gases there was only a trace of polarisation, but as soon as we introduced hydrocarbon or some particular gas in the gas, then you at once got very

* Paper read before the British Association at Edinburgh.

marked phenomena of polarisation. Start first with platinum electrodes, send a current through the secondary electrodes from a battery of 10 or 20 cells, and you get a steady current which can be measured with a galvanometer, as soon as you introduce this gas; then break the current and connect the electrodes with a galvanometer or electrometer; then you get four or five volts back E.M.F. from these cells, and the way in which the effect falls off is exactly that in which it falls off in water—the law of tracing out polarisation effect is exactly the same, of course the resistance in the air is enormous, so that the currents are very small. We found the safest way was working electrometers, with proper precautions. The falling off, so far, seems to point necessarily to some work done by the current of the nature of electrolysis, but when we introduced other electrodes, we found that the effect depended to an enormous degree on the nature of the metal which forms the electrode. With copper or iron we hardly get any effect, and that may be in itself a proof of the reality of the phenomena. In tubes after tubes, with different kinds of hydrocarbons, whatever the platinum was in itself, we got certain E.M.F.'s which we proved to be independent of a number of other circumstances, such as gas. But while with copper or iron we only got very small effects of polarisation, with magnesium the effects of polarisation increased to an enormous extent. I am almost afraid to give the number, but with magnesium electrodes after currents had been passed for a long time, so that the changes appear to take place and become permanent we got a back E.M.F. of 35 volts from a single cell. That shows it is not an ordinary effect of the gas decomposition, but that it is an effect which may be similar to that of the secondary cells, and that is what I call these effects of secondary cells. The magnesium electrodes which were used in these experiments, both a positive and negative, have on them a deposit, which appears to be a finely-divided surface of carbon, which is deposited by the discharge on the magnesium, which probably forms a loose compound with the magnesium. The gas under the influence of primary discharge is able to act as an electrolyte, in so far as the primary cells are concerned. Prof. Arrhenius has been working independently of me in the same line. His experiment was arranged a little different; he introduced plates or wires of zinc or platinum, simply connecing them to the galvanometer. The results obtained from these experiments have been already described by Prof. Arrhenius.

ON CERTAIN VOLUME EFFECTS OF MAGNETISATION.*

BY PROF. CARGILL G. KNOTT, D.SC., F.R.S.E.

The experiments had to do with the changes of the internal capacity of five iron and five steel tubes, each set having been cut from the same bar and bored to various bores. All had the same length, 18in., and the same external diameter, 1½in. The iron tubes were distinguished by the Roman numerals I. to V., and the steel tubes by the corresponding Indian numerals 1 to 5. Tubes of the same number had equal bores. Thus the internal diameter of Nos. I. and 1 were 1¼in., of Nos. II. and 2 1in., and so on to Nos. V. and 5, which had each an internal diameter of ¼in. Each tube was closed below. When set up for experiment it was closed above by a screw nut through which a capillary glass tube passed, and was then placed vertically in the heart of the magnetising coil. The whole of the metal tube and part of the capillary were filled with water, and the changes of internal volume were measured by the motion of the liquid meniscus in the capillary. In strong fields this motion was easily seen by the naked eye. It was shown at the meeting projected by the lantern on the screen. The measurements were made by means of a micrometer microscope.

The observed changes of volume amounted in some cases to nearly 5×10^{-4} cubic centimetres, and in the narrower bored and thicker-walled tubes it was evident that higher fields than those used would have produced still greater volume changes. The highest field that could be safely used was 1,100 C.G.S. units.

* Paper read before the British Association at Edinburgh.

The general characteristics may be briefly described thus: In No. I., 1 and 2, the effects were very similar, differing only in detail. In low fields the capacity was diminished, in high fields increased. In other words, the graph showing the relation between magnetising force and change of volume began by passing under the line of zero change, then crossed it and continued thereafter above it. In Nos. II. and III. a similar form of graph was obtained, only it did not reach the zero line after the maximum decrease was passed. In these cases, as in the case of No. IV., the capacity was always diminished. No. 3 showed increase of capacity in all fields from the lowest to the highest. Nos. 4 and 5 began by showing increase in low fields, but in fields higher than 200 units showed decrease of capacity. A similar but less marked effect was obtained with No V.; in other words, the graphs of Nos. 4, 5, and V. passed first above the zero line, then cut through it, and passed in almost rectilinear course below it, continuing so to the highest fields attained. The following scheme gives the nature of these changes, minus meaning a diminution of bore—i.e., an average contraction of the walls of the tube as a whole—and plus an increase of bore or average expansion. By low fields we mean fields of less than 200 units. The numbers are the greatest measured values of the dilatations, or changes per unit volume, and are maximum or minimum values in all the low fields, except in the case of No. 3 and No. IV.

Increase of Capacity (in 10^{-5} cubic cm.) of Iron and Steel Tubes.

Iron tubes.			Steel tubes.		
Nos.	Low field	High field.	Nos.	Low field.	High field
I.	17	+ 11	1	10	+ 42
II.	− 19	6	2	− 12	+ 15
III.	25	26	3	+ 12	+ 40
IV.	− 14	31	4	+ 2·4	41
V.	+ 0·5	32	5	+ 2·3	13

The greatest change per unit volume was obtained in the case of tube 4. In field 1,000 the dilatation amounted to -4×10^{-6}.

It was necessary to subject the tube to each magnetic field taken first in one direction and then in the other. If this precaution were not taken, the material got into a state of magnetic bias. Very interesting results were obtained when a smaller field was applied after a greater field, the magnetic bias, or "after-effect," due to the larger field having a very pronounced influence. To get rid of this magnetic bias it was sufficient to neutralise the tube by subjecting it to a series of fields of diminishing intensity and alternating direction.

THE ELECTROMAGNETIC STEELYARD.

BY PROF. M. H. JACOBI.

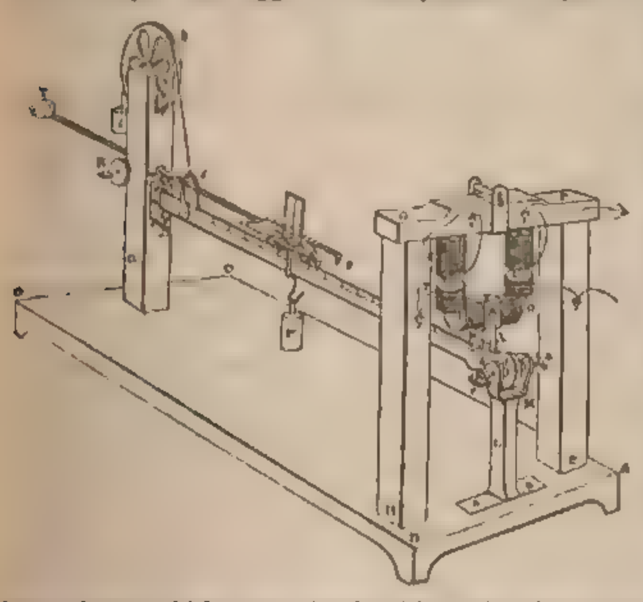
[We think this apparatus should be better known than it is, and have for a long time intended to find room for the description which we now give.—ED. *E. E.*]

A, B, C, D is a strong board resting on four feet, on this is fixed a frame, consisting of two strong posts and a cross beam, E, F, G, H. F, G is designed to support an iron bar, K, bent into the form of a horseshoe, and surrounded with copper wire.

It is of a paramount importance to secure this bar firmly in its position. L is a strong iron stem, divided at the top in order to receive in its two branches the steel screws denoted by *a* and *b*. These screws are pointed, and between them moves, with very little friction, the axis *c*, *d* of the iron lever M, N. This lever is 4½ft. long. Its upper edge is perfectly rectilinear, and fines off on each side like a sloping roof. Exactly 2¾in. from the central point of this lever it is made stronger, and is perforated perpendicularly, to receive a strong pin, which is fitted with tolerable accuracy, and which terminates above in a screw.

Underneath the pin has a nut, *e*, and is fastened below by a joint-piece, but above by a female screw, so that the free revolution round its axis is not prevented. The screw in

which the pin terminates above supports, as regulated by the female screw, a strong piece of brass, *f*, *g*, in which is firmly fixed the anchor, O, P, surrounded by copper wire. This piece of brass has on each side an oblong cleft, into which are introduced two corresponding connecting bars, fastened to the lever, of which one, *h*, is visible. It is evident that when the bolt is turned on it axis, the brass piece, *f*, *g*, together with the anchor, O, P, surrounded by wire, may be raised or lowered perpendicularly, so that the poles of the opposite horseshoe may be brought nearer, or kept further away. The end of the lever supports a gimbal, *i*, to which is fastened a string that passes over the pulley, *k*, and supports the weight, *e*, which counterpoises the lever to the post, O. This last supports the regulating plate. On the shoulder-piece, *m*, *n*, are two adjusting screws, *o*, *p*, employed partly to keep the motion of the lever within due bounds, and partly—so far as the upper screw is concerned—to check the motion of the lever, *i*, when, after the same is counterpoised, the battery circuit is complete, and the magnetic attraction takes place before the measuring begins. P′ is a running weight that hangs on a hook attached to a small waggon furnished with tram wheels, and which may be moved to and fro between the fork-like termination of a toothed rod, S, T, in which the ratched wheel, R, works. By means of a sliding bar (not visible in the sketch), the latter may be used as a catch, so that till then the toothed rod can be moved freely. The waggon carries a plummet suspended



from a frame, which must coincide with a point that is on the waggon in order to secure the horizontal position of the lever. For this purpose I afterwards applied a level. The distance from the fulcrum of the lever to the point whence the weight is suspended is exactly 4ft. 2in., that is 20 times the distance from the fulcrum to the axis of the pin, which distance has been taken at 2½in. The poles of the horseshoe, as well as those of the anchor, are cylinders rounded off, so that their four extremities and the axis of the pin may be situated in a plane at right angles to the surface of the lever. This plane may be regarded as that in which the centre of gravity of magnetic attraction is situated, so that if we designate the distance of this plane and that of the running weight, P′, from the fulcrum, by *a*, and *n*, *a*, the attractive power, $M = n, P'$. The scale on the side of the lever is divided into $\frac{1}{10}$in., so that by means of an index on the waggon of the running weight $\frac{1}{12}$th of the weight may be immediately read off, and $\frac{1}{120}$th estimated. Unfortunately, the apparatus is not strong enough in many parts to measure any very great lifting powers.

In the experiment which my colleague, M. Lanz, and myself made with it, we confined ourselves to from 200lb. to 300lb. I may also mention that there are several circumstances which, notwithstanding the utmost precautions, affect the accuracy of observations. These, experience will point out, and I may add that if anyone would desire to perform exact experiments on the lifting power of the electromagnet, he may advantageously make use of the instrument here described.

BUSINESS NOTES.

Commercial Cable Company.—This Company has declared a quarterly dividend at the rate of 7 per cent. per annum, payable October 1.

Waterford.—The inhabitants are protesting against the decision of their Town Council to abandon the use of the electric light for its streets.

Dundee.—Mr. James Small has been appointed Inspector of the conduits now being laid in different streets for carrying the electric wires.

Burnley.—The town clerk of Burnley has received from the Local Government Board sanction to borrow £23,500 for the electric lighting of the borough.

New Telephone Company.—Share certificates of the New Telephone Company, Limited, may now be received at the offices, 110, Cannon street, E.C., in exchange for bankers' receipts.

Western and Brazilian Telegraph Company.—The receipts of this Company for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,753.

Henley's Telegraph Company.—A dividend at the rate of 7 per cent. per annum on the preference shares of this Company, for the six months ending the 30th June last, will be paid on the 1st Oct. proximo.

Telephony.—The work of laying the telephone between Madrid and Barcelona is well advanced. A telephone line will shortly be installed between Teocuitatlan, Tuxcueca, Tizapan, Pueblo Nuevo, and other villages and haciendas.

Concentric Wiring.—Andrews's concentric wiring is being adopted in five of the beautiful chapels and dining halls of the colleges at Cambridge. This system has been selected to avoid the disfigurement of the interior that would result by wood casing.

City and South London Railway Company.—The receipts for the week ending September 11 were £768, against £665, for the same period last year, or an increase of £103. The total receipts for 1892 show a total increase of £724 over those for the corresponding period of 1891.

New Branch.—A new branch and showroom has been opened in Hull by Messrs. Woodhouse and Rawson United, Limited. It is at 13, Paragon arcade, and is managed by Messrs. Horne and Livingstone, under the superintendence of the Company's branch at 41, Piccadilly, Bradford, Yorkshire.

Ryde.—The traffic upon the electric tramway at Ryde is increasing, which is only natural during the summer months. The charge now is one penny for the journey. The whole installation seems to be in admirable order, and exceedingly well managed under the superintendence of Mr. Roberts.

Whitehaven.—In addition to the tenders which were notified as being accepted in our last issue, viz., those of Messrs. Ramsay Bros., Messrs. Galloway, and the Okonite Company, we understand that the tender of Messrs. Willans and Robinson for four sets of Willans engines and Crompton dynamos has been accepted.

Bradford.—The committee proposed to the Council the acceptance of tenders for the extension of the works in Bolton road, at a cost of £2,745. 9s. 4d., and the purchase of an additional length of main cable from Messrs. Siemens Bros. for the extension of the Kirkgate service. This cable will be 1,075 yards long, and the cost £828.

Bradford.—On Tuesday at the meeting of the Bradford County Council, it was stated that there had been a profit in the electricity department during the past year of £387. 7s. 2d. Since the commencement of the works in 1888 there had been a loss of £799. 10s. 8d., but it was hoped to materially reduce that during the next half year.

Scarborough.—Mr. Bernard Drake has attended a meeting of the Electric Lighting Sub-Committee and fully discussed with them the question of the electric lighting of the borough. He has been instructed to prepare a report as to the terms on which he would advise the Corporation to transfer their powers under the provisional order to a company.

Portsmouth.—The latest time for sending in tenders for the buildings pertaining to the electric light station is 6 o'clock to-day. We have carefully examined the plans of these buildings, and the arrangement seems admirable. The consulting engineer for this scheme is, as is well known, Prof. Garnett, and the engineers Messrs. Waller and Manville.

Wiring and Fitting.—We are informed that the contracts for the supply and fitting with electric light of three of the largest buildings in the City of London, namely, Leadenhall House, New Zealand chambers, and Billiter avenue buildings, comprising over 1,500 16 c.p. lights, have been signed this week by Messrs. H. Binko and Co., of 34, Leadenhall street, E.C.

Aberdeen.—As the result of the decision of the Town Council to introduce the electric light, which was reported in our last issue, in which report reference was made to Prof. Kennedy's estimated expense, he having been consulted on the subject, we understand the Gas Committee are in communication with Prof. Kennedy to ask him to make the plans and specifications for the proposed installation.

Great Western Railway The Directors are inviting tenders for large quantities of stores; among other things, for telegraph apparatus, telegraph ironwork, copper wire, telegraph poles, and, in fact, all the materials pertaining to telegraphic work. Full information can be obtained from the stores superintendent at Swindon or Paddington. Tenders must be received on or before Monday, the 3rd proximo.

Edison Swan Co This Company has just opened offices at 110, Cannon street. A portion of the space has been fitted up with specimens of the Company's manufacture. A great portion of the showroom is fitted with the exhibits which were lately at the Crystal Palace. Besides the showroom, however, storerooms are also being fitted with goods, so that orders may be supplied direct from the Cannon street premises.

Electric Light on Railways The Midland and the other great railway companies with lines running out of London are preparing to follow the example of the Metropolitan Railway and provide electric lamps for the use of their passengers. The experiment on the Underground Railway, which has now been continued for some weeks, has been found so successful that it is said 10,000 lamps have been ordered for the carriages of the Metropolitan and District.

Internal Work Messrs Vaughan and Brown have fitted the whole of the installing of electric light at the new Trafalgar square Theatre, St. Martin's lane, including all fittings and stage lighting; also at the Bedford Head Hotel, Tottenham Court road, for Mr. Woods, with 800 lamps; the Marble Hall, Strand, for Messrs Gatti Bros; also No 75, Strand, with 200 lamps; the Albert Music Hall, Canning Town, with 600 lamps and plant complete; and the Polytechnic Institution, Regent street.

Brush Company The Directors of the Brush Electrical Engineering Company, Limited, have resolved to recommend to the shareholders that, subject to audit, a dividend at the rate of 6 per cent per annum be declared on the preference and ordinary shares of the Company for the six months ended June 30, 1892 making, with the interim dividend paid last February 6 per cent for the year upon both classes of shares. The transfer books of the Company will be closed from September 19 to 28, both inclusive.

Siam Electric Light Company The affairs of the Siam Electric Light Company are at length to be satisfactorily settled: £20,000 has been advanced by the Treasury out of which the creditors are to be paid. The Brush Company, on receipt of the first instalment awarded by the recent court of arbitration, will send out a staff of men to put the machinery in order, after doing which they will receive the balance of the sum due to them. The concern will then either be put up to auction or taken over by the Government by private arrangement with the Company.

Personal Mr W. H Stevenson informs us that he has resigned his position as country traveller to Messrs Woodhouse and Rawson United, Limited, and has accepted a position as town traveller with Messrs Laing, Wharton, and Down, of 82A, New Bond street W. After a connection of 10 years with Messrs Woodhouse and Rawson, Mr Louis Brockman has resigned his position as supply superintendent, and availing himself of an offer from Mr L. Epstein, the managing director of the Epstein Electric Accumulator Company, Limited, has been appointed manager of that Company.

Western Union Telegraph Company This Company announce that a new office has been opened at 40, Mark lane, E.C., for the reception and delivery of messages for and from all parts of North, Central, and South America, Canada, Bermuda, Bahamas, West Indies, etc. This Company owns the largest telegraphic system in existence having two Atlantic cables, both duplexed, running from Penzance, via Canso, into New York City, connecting with its land line system which comprises 725,000 miles of wire and 21,000 telegraph offices. The central cable office in New York has direct wires to Galveston, Texas, connecting at that place with the cables of the Mexican and Central and South American Telegraph Companies; and also direct wires and cables to Havana, Cuba connecting at that place with the Cuba Submarine and West India and Panama Telegraph Companies for all points in the West Indies.

New Catalogue. We have received from Messrs Dorman and Smith, of Ordsall Works, Manchester, a copy of their most recent catalogue, which contains an illustrated price list of their various manufactures, such as their patent porcelain lampholders and switches. We have at various times illustrated these lampholders and switches, and, so far as we are aware, porcelain has shown that it is admirably adapted for use in this direction. The other illustrations and prices are those of a variety of balance suspension pendants of various kinds, and fittings of every type for shipwork and millwork. It is hardly in our province to enter into the question of cost: the customer must compare the prices of one manufacturer with those of another, remembering always that the lowest priced fitting may in the long run be less economical than a higher priced fitting. Much depends upon the material used and the workmanship employed.

Country Houses It is satisfactory to find that Wales is moving with the times in the way of electric lighting. Messrs F. B. Saunders and Co. have just completed an installation at Velindra for Mr Vyvyan Robinson. The house and stables are lighted throughout, the motive power for charging the accumulators being obtained from a Priestman oil engine, this being the second engine of that type which the above named firm have supplied in this district during the past few months. The same firm have just received instructions to proceed with the lighting of Cottrell for the Mackintosh of Mackintosh, and when completed this will be one of the most important installations in the country. Messrs Saunders and Co. have the lighting of Ely Court now in hand for Mr Insole, and are also arranging for several other large installations in the district. This all points to electric lighting becoming almost universal at no very distant date.

Direct Spanish Telegraph Company. The report of the Directors for the half year ended June 30 states that the accounts for the half year show, after providing for debenture interest, a balance to the credit of profit and loss of £6,178. The traffic receipts show a decrease of £45 as compared with those of the corresponding period of 1891. They may, however, be considered satisfactory, as in the half year of 1891 with which they are compared the present reduced tariff had not come into force. The working expenses are £170 in excess of those for the corresponding period of last year. After putting the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £2,938. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares and a dividend at the rate of 4 per cent. per annum, free of income tax, on the ordinary shares. A balance of £441 will be transferred to the reserve fund.

Southampton. The electric light installation at Southampton is progressing slowly. The apparatus installed is sufficient to generate electricity for about 3,000 lamps. It consists of Marshall's boilers, supplying steam to a Robey engine, which drives a Crompton dynamo for the heavy work. For the lighter work a combination of a Willans engine and Crompton dynamo is used, and this also charges, we believe, three sets of batteries installed. The whole installation is under the charge of Mr. Moncrieff. We understand that the channels for the electric mains have been made from the ground clinkers obtained from the Southampton municipal destructors. It ought to be well known to most people that the ground clinkers from a destructor, mixed with cement, makes a far better mortar than the best sand. At an inspection of the new baths and washhouses the other day we noticed that an electrical generator, supplied by Mr F. M. Newton, of Taunton, has just been erected, and in the course of a few days will be at work.

Leeds Tramways. The negotiations for the acquisition of the entire tramway system of the borough, excepting only the Roundhay Park electric cars, is progressing. The Board of Trade have approved the proposal of the Corporation to serve notice upon the tramways company requiring them to sell the local authorities their undertaking, and the Corporation have instructed their town clerk to serve a notice upon the Company. The town clerk was also instructed to apply to the Board of Trade for the appointment of a referee to fix the price at which the Corporation may acquire the tramways. Progress has also been made as to the purchase of the New Wortley and Meanwood road sections, which do not come under the compulsory powers. The proposals of the Company in a draft agreement have been approved, subject to a few alterations. At the meeting of the Tramways Sub Committee the other day, a letter was read from Mr Graff Baker calling attention to the fact that his agreement with the Corporation for the working of the Roundhay road electric cars terminates on the 31st October next. It was decided to recommend that the agreement with Mr Baker should be extended for a period of 12 months from the date mentioned, on the same terms as before.

Essex Shire Hall The County Councillors of Essex had a recommendation from the Shire Hall Sub Committee under their notice at the last meeting, that Mr M. I. M. Williams be required to make a general preliminary inspection and report as to the probable cost and nature of the work of lighting the shire hall by electricity. The chairman of the sub-committee moved the adoption of this report, and a long discussion ensued, when Colonel Howard moved the rejection of the recommendation, and his amendment was finally carried by 15 to three, 15 members voting for the amendment and three against it. The Essex County Council seem to have a very exalted opinion of the powers of its sub-committee, for subsequently to the rejection of the recommendation it was proposed that the sub-committee should report upon the best means of improving the atmosphere of the courts, and this proposal was carried, but a motion which was also made that an expert should be engaged was lost. In other words this sub-committee of the Essex County Council is supposed to have a sufficiently practical knowledge to make a report that will be worth dealing with. It would not be surprising when the committee report to find that, among other things, recommended for improving the atmosphere would be the introduction of the electric light. At any rate, if it is a question between gas and electricity, we are quite sure that electricity will assist somewhat in making the atmosphere less obnoxious.

Electric Pumping Plant A few days ago a supper was given at the Peddlers Arms Hotel, Hirwain, to a number of workmen and officials of the Aberdare-Merthyr Colliery, in celebration of the starting and working successfully of an expensive electric plant for pumping, erected at the above colliery, owned by Messrs. the Aberdare Merthyr Collieries Company, Limited. The plant was supplied by the well known firm of electrical engineers, Messrs. the Crompton Howell Electric Power, Light and Storage Company, Limited, Llanelly, under the management of Mr G. Beith, of Pontypridd and the careful supervision at the colliery of Mr Joseph H. Evans, now of Cross Inn, formerly of Ynysybwl. The electric power is

supplied by one of Crompton's compound dynamos, driven by one of Marshall and Sons's engines, of 150 h.p., having a flywheel of 14ft. diameter, weighing about $7\frac{1}{2}$ tons, and grooved for 16 1in. diameter ropes. The power is conveyed to the pumps, which are about 2,000 yards from the surface, by means of cable supplied by Messrs. Callender and Co. The pumps, three in number, were built by Messrs. Warner and Son, Walton-on-the-Naze; one has three plunges, 10in. by 18in. stroke, the other two have three plunges 6in. by 9in. stroke each. The water is cleared in the course of eight to nine hours daily, thus doing away with night pumping. This step has been a great benefit to the Company and workmen, as the Company suffered a deal of trouble and expense by keeping the water down by means of steam power, and the workmen losing time and having to work in intense heat owing to the steam connection.

City of London Electric Lighting Company, Limited.—The Directors of this Company have issued a full report of the meeting, which, however, is but little more in detail than our report which appeared last week, though the report as issued contains a number of figures which it is always difficult to obtain with accuracy from a speech. From this we may give the following extract: "The contracts with the City for arc lighting in main thoroughfares required the laying of trenches in 47,072 yards of streets. On June 30 43,134 yards were laid, and now 45,410 yards, leaving to complete 1,662, which will be finished during the next two or three weeks. Of the work in the lesser streets, which is not compulsory, on June 30, trenches were laid 46,378 yards in length, or about $26\frac{1}{2}$ miles; now there are completed 49,412 yards. There has been laid to this date 303 miles of ways. The length of cables drawn in to date is $63\frac{1}{4}$ miles of high tension, and 22 miles of low tension. On June 30 there were in the streets 184 arc lamps, now there are 334. By the middle of this month all arc lamps under the City contracts will be running, excepting a few delayed for special reasons, such as building operations, reconstruction of refuges, etc., our last day really being November 5, so that we are unlike most contractors in being ready before our time. On June 30 there were 11,800 8-c.p. glow lamps on 6,735 yards of main, giving a lamp density of two lamps per yard of main. If this density were to hold good throughout the area of the street work now ready to receive mains, this would give 100,000. In Lombard-street the density is six lamps per yard, and in Cornhill it is very nearly the same." With the report there are a series of very interesting curves, and which, if followed by similar curves year after year, will enable everyone at a glance to see and to answer a great many questions as to progress and cost.

Chelsea.—The surveyor to the Vestry thus reports to the Vestry upon the electric lighting of the district: "At the beginning of the year the Vestry had under consideration the St. Luke's, Chelsea, Electric Lighting Order, and decided to offer opposition thereto, although it was drawn up on the lines of the Board of Trade model order. In April I attended with the chairman of the Electric Lighting Committee at the offices of the Board of Trade, and the Vestry's objections were stated to Mr. Courtenay Boyle and subsequently embodied in writing. The Board of Trade, however, in reply stated that the provisions to which the Vestry objected had been inserted in so many provisional orders which had been confirmed by Parliament, that they could not accept the amendments. The Vestry informed the Member for Chelsea of their objections, but did not at first see their way to appealing direct to Parliament. The matter, however, I considered of such importance that I again brought it before the Electric Lighting Committee, who authorised the preparation of a petition to Parliament against the Bill. The Vestry opposed the Bill in the House of Lords, and, in spite of the objections of the County Council, obtained the desired alterations so as to make the Vestry the electrical authority for the parish of Chelsea.

"At the end of July the Vestry appointed me an inspector under the Electric Lighting Acts, so as to empower me to examine the records of pressure, etc., kept by the electric lighting companies. The Cadogan Electric Lighting Company, not yet having complied with that Act as regards a money deposit, the Board of Trade have not served them with the usual regulations as to safety and supply, so that the only company keeping records which the Vestry's inspector can examine is the Chelsea Electricity Supply Company. From time to time I have inspected the records kept by this company, and find that the pressure recorded by their instruments is always above 100 volts, it usually being about an average of 103 volts, except on one or two occasions when alterations were being made to the engines. I consider that their system shows very satisfactory results, and I am of opinion that they keep well within the limits laid down in the Board of Trade regulations.

"The number of houses lighted by electricity in Chelsea was:

	1889-90.	1890-91.	1891-92.
Chelsea Electricity Supply Company	113	215	312
Cadogan Electric Light Company	25	16	18
London Electric Supply Corporation	1	2	2
	139	233	332

It thus appears that about 100 houses have adopted electric lighting during each of the last two years.

"The Overhead Wires Act, which was passed in July, provides that by-laws for the regulation of such wires were to be made by the County Council with the approval of the Board of Trade. In December the Council forwarded a copy of the suggested by-laws to the Vestry, and certain slight alterations I suggested therein were approved by the Vestry and forwarded to the Board of Trade, but at the end of the year no enquiry had been held, nor had any by-laws been approved. On November 3rd I was formally appointed by the Vestry inspector of overhead wires under the London Overhead Wires Act."

Blackpool.—We were able in our last issue to give the definite statement that the troubles relating to the Blackpool tram lines had been sufficiently overcome, and that the Corporation were to purchase for a stated sum. We believe that last Friday a cheque for the sum of £15,750 was paid in to the account of the Blackpool Electric Tramway Company, and that on Saturday the Corporation commenced to run the line, Mr. J. Hesketh, the Corporation's electrical engineer, taking charge in the place of Mr. J. Lancaster, the latter gentleman remaining as outdoor traffic manager. The *Blackpool Gazette* gives the following information upon the whole question: "The Directors of the Company had sent in a claim for over £18,000, as being the amount they required for the transfer of the works in Princess-street, the cars and the electrical installation generally. Auditors on behalf of the Corporation had gone through the accounts and found the sum the Company were really entitled to was £14,840. However, there had to be a give-and-take principle adopted, and as a result of the first part of the conference, the Directors reduced their claim to £16,000, and the Corporation representatives increased their offer by slight advances to £15,500. Neither side, however, were prepared to give in any further, and a deadlock was arrived at. Threats were now used on both sides, the tramway directors intimating that they would refuse to permit the Corporation to work the line after Friday unless their claims were satisfied. The members of the Council, however, responded that they did not fear any action the Directors might take, as they had no doubt a mandamus compelling them to hand over the works could easily be obtained. The negotiations were thus broken off and the parties were separating—in fact, some of the gentlemen had left the room—when, fortunately, wiser counsels prevailed, and the Mayor and Mr. Horsfall, chairman of the directors, had a word or two together. The result was that the Corporation representatives offered to 'split the difference,' to divide the £500 in dispute, and the Directors accepting this decision it was therefore definitely arranged that the price to be paid by the Corporation for the whole of the electrical installation should be £15,750. All things considered, this arrangement may be said to be a very satisfactory one, as it prevents many difficulties and considerable expense in the way of arbitrations, etc., in the future. The next course will be to wind up the affairs of the Blackpool Tramway Company, and after returning the original capital invested by the shareholders, it is expected that they will receive a fairly handsome bonus. The Company have altogether issued 3,000 shares, but upon 2,850 of them only £8 10s. has been called up. One hundred and fifty shares of £10 each have been allotted to Mr. Holroyd Smith under the agreement of seven years ago. The total share capital therefore is £25,725. In the last balance-sheet, the Company showed a sum of £6,069 in hand as a depreciation and reserve fund account, £2,000 of this amount being invested in the Bank of New Zealand, and £1,500 in the Bank of British Columbia. Then, of course, the profits for the present year, which should amount to close upon £3,000, will be available for distribution among the shareholders. Add these approximate amounts to the £15,750 they are receiving from the Corporation, and you have a total not far short of £24,000. All things considered, therefore—though, of course, we do not advance these figures with any definite degree of accuracy—the shareholders should receive a very handsome bonus upon their original investment, in addition to the good dividends—last year's was $7\frac{1}{2}$ per cent.—they have been paid during the last seven years. Mr. Alderman Bickerstaffe, who owns 115 shares, is the largest holder on the Board of Directors; Mr. T. Shaw, M.P., owning 58, Mr. T. Ormerod 30, Mr. T. H. Morris 20, Mr. J. Addie and Mr. J. Broadbent 10 each."

Barnet.—At a special meeting of the Local Board on Thursday in last week, the question of the electric lighting was formally discussed. As we have previously stated, a committee has been obtaining information, which may perhaps assist others if we give the replies obtained from Chelmsford and St. Pancras to the questions which were prepared by the clerk of the Board.

How long has the electric light been in use in the district?—Chelmsford: Since April 14, 1890. St. Pancras: Since last November.

Do you use it for public or private lighting, or for both?—Chelmsford: Both. St. Pancras: Both.

What is the area lighted?—Chelmsford: Thirteen miles of streets. St. Pancras: Five and a half miles public, five and a half miles private.

Is the light supplied by yourselves or by a company?—Chelmsford: Crompton and Co., Chelmsford Electric Lighting Company, Limited. St. Pancras: Ourselves.

Does your system of private lighting pay, and if so, to what extent?—Chelmsford: No answer. St. Pancras: No answer.

Under what authority, special Act, provisional order, license?—Chelmsford: License from Board of Trade; minimum, five years. St. Pancras: Provisional order, confirmed by Act.

Has more than one company been admitted into the district? Has any inconvenience been experienced therefrom?—Chelmsford: No other company. St. Pancras: None.

What system is in use for public lighting?—Chelmsford: incandescents 32 c.p., alternating transformer system, parallel; arcs 1,000 nominal, direct current (series). St. Pancras: Parallel wire, high tension.

What candle-power lamp is found to combine efficiency and economy, (*a*) as to public, (*b*) as to private lighting?—Chelmsford: 32 c.p., 80 c.p. lamps where possible. St. Pancras: Nominal 2,000-c.p. public, 10,000 16-c.p. private.

What is the cost of the light, as compared with gas, having regard to the illuminating power? Chelmsford 32 c.p., £2 6s 10d; arcs, £22 10s., cleaning, etc. St Pancras No answer.

What is the price of gas per 1,000ft., and what do you charge per unit for electricity? Chelmsford: Gas, 4s. 6d *Vide* agreement. St. Pancras. 2s 2d gas per 1,000ft public; 6d. per unit Gas, 2s 9d per 1,000ft. for private consumers.

Is payment made by meter or by periodical sums (*a*) for gas, (*b*) for electric light? Chelmsford. Streets per lamp, private by meter St Pancras By meter.

What method is adopted to provide against failures of the light? Chelmsford All plant is duplicate St. Pancras: Good plant.

How is uniformity and steadiness of light maintained? Chelmsford: No answer. St. Pancras: Seven machines; two spare.

Are the lines carried overhead? Has any accident or inconvenience been experienced therefrom?—Chelmsford: Overhead; no. St Pancras Underground

What control is possessed by the lighting authority over the undertakers *a* as to charge for private lighting, *b* as to public safety or damage to property, (*c*) as to interference with roadways or footways? Chelmsford License St Pancras: Dual control

What was the cost of obtaining your order beyond the £50 deposit to the Board of Trade (*a*) with regard to the printer's charges, (*b*) solicitor's costs, (*c* machinery? If the provisional order is in your own hands, do you practically sublet it to a contractor? If so, at what cost?—Chelmsford About £100. St. Pancras Total £250. No.

Had you any opposition, and was it successful? Have you successfully objected to any application from outside undertakers? Chelmsford No opposition either way St. Pancras Not known. Order obtained 1883 Application 1890 was made by another company. Vestry asked Council to extend order

Other information was received from Maidstone and from Chatham, and the committee recommended "that the Board take the necessary steps to obtain their own provisional order in the ensuing session" After a long discussion, the reports of the committee were adopted, and by another motion the Electric Lighting Committee was reappointed with an additional member

PROVISIONAL PATENTS, 1892.

SEPTEMBER 5.

15876. **Improvements in and relating to telephonic instruments** James Muirhead, 96, Buchanan street, Glasgow.

15887. **Improvements in and apparatus for obtaining metals by electrolysis.** Hans Heinrich Frei, 46, Lincoln's inn fields, London

SEPTEMBER 6.

15958. **Cox's "Multum in Parvo" electric top band for boots** Charles James Joseph Cox, 81, Lavender hill, Clapham, London.

15959. **Improvements in pneumo dynamo meters** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall gardens, London

15960. **Improvements in the means of conveying or administering electricity for medical purposes or others** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall gardens, London

15961. **Improvements for charging vapours for inhaling purposes or others with electricity** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall gardens, London.

15962. **Improved means for administering electricity to animals or human beings** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall gardens, London

15963. **Improved means for administering or conveying electricity for medical or other purposes** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 55, Cornwall gardens, London.

15969. **Improved electric cork ribbed belt** George James Speed, 18, Denman street, Regent street, London

15972. **Improved arrangements of pulleys and bands for driving machines from electromotors** Siemens Bros and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs Siemens and Halske, Germany)

15991. **The manufacture and production of compositions of matter suitable for use for bearings, packings, projectile guides or rings, electrical conductors and analogous articles.** Philip Henry Holmes, 47, Lincoln's inn fields, London. (Complete specification)

15992. **Improvements in the manufacture of composition bearings, packings, projectile guides or rings or analogous articles, applicable also for use as electric conductors** Philip Henry Holmes, 47, Lincoln's inn fields, London (Complete specification.)

15994. **Improvements in electrical conductors** Philip Henry Holmes, 47, Lincoln's inn fields, London (Complete specification)

15998. **Improvements in the manufacture of electric circuits and cables** Alfred Vincent Newton, 6, Bream's buildings, Chancery lane, London. (John Arnold Barrett, United States.) (Complete specification.),

15999. **Improvements in the manufacture of electrical circuits, cables, and other articles alike subject to flexure.** Alfred Vincent Newton, 6, Bream's buildings, Chancery-lane, London (John Arnold Barrett, United States) (Complete specification)

SEPTEMBER 7.

16014. **Improvements in phonographs.** John William Mackintosh, 55, Chancery lane, London (Complete specification)

16046. **An improved process of and apparatus for the electrolytic decomposition of alkaline salts.** Hamilton Young Castner, 55, Chancery lane, London

16055 **Improvements in dynamo-electric machinery** Thomas Richard Freeman and William Waller Pope, 45, Southampton-buildings, Chancery lane, London.

SEPTEMBER 8.

16114 **Improvements in signalling announcing and advertising by electric or other light on the clouds or other vapour, and in apparatus therefor.** Edward Curtice, 77, Chancery lane, London

16124 **Improvements relating to telephonic switching apparatus** Alfred Rosling Bennett, 45, Southampton-buildings, Chancery lane, London.

16128. **Improvements in soldering joints of electric wires** Walker Moseley, 82, Montpelier road, Peckham, London.

SEPTEMBER 9.

16138. **Improved means for transmitting telegraphic signals through submarine and like cables.** Henry Alfred Charles Saunders, 124, Chancery lane, London

16142. **Improvements in telegraphic receiving instruments** Johannes Feydenlahl Hoffgaard, 17, St Ann's square, Manchester (Hans Peter Fryd, Denmark)

16176. **Improvements in the means or apparatus for measuring electricity** Edward Howard Percy Humphreys and William Friese Greene, 35, Chancery lane, London

SEPTEMBER 10.

16201. **Improvements in galvanic batteries.** Jean Baselli Fachris, 151, Strand, London.

16234. **An improvement relating to electrical switches, sockets, cut-outs, and like electrical appliances** Samuel Thomas Wynd and Louis Schraumm, 9, Warwick-court, Gray's inn, London

16262. **Improvements in the electrolytical decomposition of alkaline chlorides for the production of chlorine and alkalies and in apparatus therefor** Camille Alphonse Faure, 46, Lincoln's inn fields, London

NOTES.

Havre, like Portsmouth, is to have transformers under the public streets.

Platinum, in good quality and of considerable quantity, has been found on the Pacific coast.

Houses of Parliament.—The House of Lords is to be lighted throughout by electric light.

Electric Velocipedes will be made for sale shortly by the Société des Etablessements Decauville at Paris.

Heilbronn, the only town using the multiphase current in a central station, has already a demand equal to 4,200 lamps.

Popp Company.—M. Victor Popp is leaving the post as director of the Popp Company to take the position of consulting engineer to the company.

Specifications.—A work entitled "Electric Lighting Specifications" has been issued by Mr. E. A. Merrill, at the W. J. Johnston Company, of New York.

Ammonite.—The new explosive, ammonite, by the use of electric firing and careful tamping, does away with any flames, and is coming into use for fiery mines.

Crewe.—A definite scheme for the establishment of a technical institute at Crewe is being considered. A special feature will be made of engineering in all its branches.

Coast Communication.—It was stated at the meeting of the Dover Town Council on Wednesday that the East Goodwin lightship is to be telegraphically connected to Dover.

Church Decorations in Paris.—The church of the Sacred Heart, on the heights of Montmartre at Paris, has been lighted up during the celebrations with a large cross of electric lights.

Atlantic Lightships.—The French Transatlantic Company is stated to be considering a proposal that light ships connected by telegraph cables be stationed at intervals of 300 miles across the Atlantic.

Telephone in Austria.—The long distance telephone between Trieste and Vienna has been connected to Prague, a total of 728 miles. From end to end the sounds are perfectly clear, and conversation is carried on with ease.

Electric Fly Trap.—A new fly trap is driven by an electric motor, and kept in shop windows. It drives a broad band smeared with some sweet substance, the flies alight, and are carried along, and then swept off into a wire trap.

Naval Indicator.—The Italian Minister of Marine has definitely adopted an electric indicator invented by an officer of the Italian naval service, and the commandant of the navy has expressed his opinion that it is of incontestible service.

Cyrus Field's Mementos.—Mr. Cyrus Field's collection of curios, medals, and reminiscences of the laying of the Atlantic cable, which, besides his insurance, were all that remained of his once princely fortune, will be exhibited at the Chicago Exhibition.

Barnard Castle.—A correspondent to a Teesdale paper says that in his visit to Ireland he saw both Dublin and Londonderry lighted by electricity, and the lighting was satisfactory. He says the town of Barnard Castle has the advantage of water power and could easily adopt the new illuminant.

Book Received.—We have received from M. Julius Springer, of Berlin, the issue of *Fortschritte der Elektrotechnik* for 1891, being the fifth year of appearance. It contains a large and carefully-arranged mass of information upon electrical subjects, and the advance of electrical industry in Germany generally.

Spain.—The central installations in Spain are extending, much work being done by the firm of Planos, Flaguer, and Co., of Barcelona. The firm have lighted some 20 towns in Spain, and the contract for Tolosa has been awarded to them, in spite of severe competition from foreign firms. It will comprise three turbines of 26 h.p. each, working at a fall of 460ft.

Mount Washington.—The electric search-light on Mount Washington enables a newspaper to be read at Maplewood, 17 miles away. A peculiar appearance is noticed against the white walls of the hotel of dark spots the size of a leaf, floating in the light, which are thought are probably due to the magnified shadow of minute dust specks near the intense arc.

Alhambra.—The Alhambra Music Hall has been beautifully decorated and fitted up with electric light in electroliers of special design round the balcony fronts, and upwards of 120 incandescent lamps have been placed in front of mirrors in the grand circle and stalls. The electroliers are in hammered metal, finished in silver and gold ormolu, and present a most handsome effect.

Car-Motor Regulation.—Herr Kolben having claimed for Sprague the first introduction of combined field-magnet coils instead of resistances for the regulation of electric car motors, M. Reckenzaun writes to the *Electrotechnische Zeitschrift* to say that he patented a similar combination in 1884, and that one of his cars fitted with this regulation was run experimentally in Berlin in that year.

Canal Boats.—The trolley system applied to canal boats is now being once more urged. It would be interesting to know if any experiments or trials whatever have yet been made in this direction. The bargee is proverbially an ignorant and rather degraded specimen of humanity. The smart electrical engineer is replacing the horsey element to some extent, and may invade the domain of the lazy bargee, with profit to his own soul and the purse of his master.

Belfast.—A "Mill Manager" writes to the *Belfast News Letter* to raise the question of introducing electric light into that town. He says he spends over £250 a year for gas, and is told by his friends that they find great benefit from electric light. He thinks that if the Corporation undertook the supply, numbers of mills would take it, and wishes to know the cost. Probably the *News Letter* would insert a contribution from responsible firms giving a few details.

Milan Exhibition.—The proposed electrical exhibition at Milan is to be privately carried out. A charge of 10f. to 20f. per square metre will be made. The programme is extensive, including generators, mains, motors, telegraphy instruments, medical, raw material, engines, teaching historical, literature, and plans for electrical installations. Particulars can be obtained from the Comitato Esposizione di Electrotechnica, Via Amone 9, Milano.

Atlantic Telegraph.—That most interesting and even exciting work, the "History of the Atlantic Telegraph," is about to be issued in a revised form by Mr. Henry M. Field—Mr. Cyrus Field's brother. It was first issued in 1866, and in its revised form should form one of the books necessary to the library of every electrician. It is also one of the best books possible to give to a lad for a Christmas gift—far preferable to fire the enterprise and

inventive imagination than the usual schoolboy adventures, and while being quite as exciting has the inestimable advantage of being true.

Train Lighting.—In the discussion on a paper by Mr. E. C. Riley on "The Development of Gas Lighting in Trains," before the South-West of England District Association of Gas Managers, the author said: "Several railways that have experimented to a considerable extent with the electric light, but have now adopted gas lighting, are in consequence using larger lamps and better burners; the consumption being nearer one cubic foot than the ½ft. previously used." He also remarked that the heavier and darker upholstery in the first-class carriages necessitated the use of two lamps to give as good a light as the lighter and less-upholstered second and third-class carriages.

Electric Lighting of Frankfort-on-the-Maine.—We have received a copy of a printed report prepared by Messrs. W. H. Lindley and Oscar von Miller concerning the proposed central station for Frankfort-on-the-Maine. This report, which is addressed to Mr. Adickes, the mayor of that town, deals generally very fully with remarks made in letters to the mayor in August by the Accumulatorenfabrik Actien-Gesellschaft, of Hagen, and Messrs. Schuckert and Co., of Nürnberg, both of whom had presented schemes for the electric lighting of the town. The reporters do not see their way to any material change being made in the advice given in their previous report made in June last.

City of London College.—The prospectus of the City of London College, or, as it is also termed, the City Polytechnic, contains a very extended list of classes, ranging over 63 different subjects, from agriculture to wood carving, including arts, languages, and sciences, all at the most moderate fees of three to ten shillings per term. Membership at half a guinea entitles to numerous advantages, besides admission to classes at reduced fees. Much attention is given to engineering instruction, and the college in Moorfields evidently gives great opportunity to hard-working students to give themselves higher instruction in special subjects, which they may make good use of for future progress.

New Ventilator for Underground Conduits.—With a view to extract any coal or other explosive gas which may find its way into underground conduits and close to manholes, and so prevent explosions in case of short circuits, the Paris Muncipality has introduced a portable ventilator which can be trundled and worked by one man. It is a centrifugal turbine mounted upon two wheels, and when the hauling handle is lifted up the ventilator is lowered and fits accurately into the top of a manhole, when, of course, the cover is removed. It is possible in the short space of 10 minutes to renew the air in a 600-metre length of conduit, but the Town Council only uses the ventilator for 100 metres at a time. This portable machine has already been successfully applied to the municipal electrical conduits, and one electric light company in Paris is about to adopt it. The idea is worthy of emulation.

Institution Portraits.—Every member and associate of the Institution of Electrical Engineers received, a few months ago, an invitation from Messrs. Barrauds, photographers, of 263, Oxford street, to be photographed for the large picture of the Institution which they proposed to prepare. A free proof of the portrait was sent to each person who accepted the invitation, and now the large photograph is ready. We have received a copy of the photograph, in which the figures of the honourable and ingenious company of electrical engineers are grouped in an imposing hall with side galleries. It is accompanied by a key, 537 being the total number of members present. Those who wish to possess this interesting portrait group can obtain it for two guineas, or framed for a little extra. A key photograph will accompany each picture, which certainly forms an interesting personal reminiscence of the Institution.

Single Arc Lamps.—Arc lamps on a 110-volt circuit are usually run two in series, and if only one lamp is required this means wasting a large amount of voltage in resistance. Why not use incandescent lamps as resistances for the arc lamps, asks Herr C. Heim, and he experiments and reports at length upon his thesis. He used four, six and nine ampere lamps, and concludes that it is perfectly possible to use incandescent lamps thus, and that they may be used for lighting, their fluctuation being not more than 10 per cent., and often not over 6 per cent. He says "With the application of groups of incandescent lamps, an arc lamp burns as quietly as if the excess of voltage were absorbed for wire resistances, and better than if burned in series with a second arc lamp." The protection of the incandescent lamp is secured by a small resistance consuming five volts, which is cut out of circuit after starting. The system has been employed for some time in the Central Hotel of Berlin.

Telegraph Improvement.—The Associated Chambers of Commerce, at their meeting at Newport (Mon.) on Wednesday, passed some recommendations to the Post Office with reference to improved telegraphic communication. In the first place, a resolution was moved that the executive should take steps to obtain telegraphic facilities from all railway stations not closely adjacent to public telegraph offices. This was passed with the addition that telegrams should be retransmitted by telephone where facilities existed. On the motion of the Wakefield Chamber, a resolution was carried that it was unfair to the public to consider the telegraphic department as a separate financial concern as causing unwarrantable delay in much needed reforms, and that the time had now arrived when the address, if not exceeding six words, should be transmitted free. A deputation is to wait on the Postmaster General to urge upon him the adoption of this suggestion.

Exhausting by Mechanical Pumps.—Every improvement in the manufacture of incandescent lamps is being watched with the keenest interest in England at the present moment, when so many manufacturers are holding themselves ready to spring forward upon an open market of the magnitude this has now assumed. A season of cutting prices will set in, and no means to secure economy with efficiency will be left untried. The method recently introduced in America of exhausting the bulbs by mechanical pumps jacketed with a vacuum chamber, seems likely to render considerable service in reducing the cost of this delicate part of the process. A recent test shows the character of the vacuum to be high—higher even than that usually obtained by mercury. A lot of two dozen lamps, after burning 350 hours, only showed a falling off of 1 c.p., with but the slightest trace of blackening. The cost of exhaustion is also very much less on this system than with mercury pumps.

Making it Simple.—Our cousins on the other side have the knack of making people understand, even if they are not scientifically accurate. This is the way voltage has been explained by *Stone* "When a criminal is electrocuted in the State of New York, the newspapers tell how many volts they hit him with, which forthwith sets the reader to wondering what is meant. We might explain this way. Suppose we had a body of water 1ft. deep, to

the bottom of which we attach a hose with three-fourths nozzle, and play the stream on a man at a distance of, say, 4ft. He would, of course, know that he was getting doused with a stream of water, but it would have no other effect. In this case we would be hitting him with what we will call one volt of water, but he would not mind it a bit, as he would scarcely know he was being hit. But suppose we change the hose from the 1ft. head of water to one of 200ft. in height, and let loose on our imaginary criminal. This time we hit him with 200 volts instead of one as before, and if conscious at all, he is conscious that something has hit him, and hit him hard."

First User of the Telephone.—In a recent interview, Prof. Graham Bell says that the first actual telephone line for use was run from Somerville to the office of Stone and Downer, bankers and brokers, 15 years ago. "Mr. R. C. Downer," he says, "now president of the Broadway National Bank, was the first to use it, and when I recall the crude manner in which the line was then constructed, I am surprised that it worked at all." He thinks a great deal of useless talk is indulged in, and advises the tollage system as likely to stop indiscriminate talking, and to conduce to better use for business men. He thinks there is a fortune for the man who will simplify the switchboard service. Mr. Downer, already spoken of, was a young man at the time of the invention of the telephone, and wished to invest, but his father declined, and the chance for future millions thrust upon him were thrown away. The first paid message ever sent over a telephone was sent by Prof. Bell to his *fiancée*, Miss Hubbard, in Cambridge. It was sent from Somerville to Boston (which was the extent of the line at that time) by telephone, and thence by paid messenger to Cambridge.

Foundations.—One of the most important duties of the consulting engineer to a town or public electric company is to be sure that the site is far enough from likely complaints of nuisance, or if in the town that the foundations are of such a nature that no vibration is felt in the houses around. Few electrical engineers except the managers of public supply companies know to what extent complaints are, with reason and without, urged against electric works. The Grosvenor installation was simply bombarded with complaints and injunctions, and the officers' lives were rendered miserable by the constant complaints. They have gone far enough from such a danger now, however. Now there is Morecambe, the Hastings of the North, bearing its tide of complaint on the same score. At the Local Board meeting a deputation of lodging-house keepers attended to protest against the vibration of the machinery of the electric light company's central station in Edward-street, which damaged their business, frightening away intending visitors. The deputation were advised to sue the company for damages, and the chairman said the Board would do what they could to have the nuisance remedied.

Automatic Controller.—In certain cases it is found advisable, on account of simplicity, to charge by the number of lamps lighted, instead of by meter, for energy supplied. The company so supplying must have a check to prevent a larger number of lamps being lighted than is bargained for, and M. Laille has recently perfected for these circumstances an ingenious controlling apparatus, which is described diagrammatically in *L'Electricien*. A swinging armature is pivoted between the poles of an electromagnet which has three windings, one being in the same direction as the main winding, and the other opposed. These are connected in such a manner that which the resistance in the circuit decreased beyond a fixed amount, as when too many lamps are thrown in, the armature swings over and cuts in a large resistance to the lighting circuit, and all the lamps go down to a dull red. This, of course, is sufficient indication to the householder that he is exceeding his agreement, and the armature swings back when a few lamps are turned out. To illustrate the sensibility of the Laille controller, we are told that one of these instruments was set for 60 lamps on a circuit of 110 volts, and it was found impossible to light more than 62 lamps.

Elihu Thomson's Telephones.—Telephony is a peculiar business, inasmuch as the wholesale supply does not become cheaper than a retail or smaller supply, but rather the reverse. Switchboards are more costly, batteries and instruments have to be inspected and tested, and multiplicity of wires adds to the difficulty. New systems to vary or obviate practical disadvantages are brought out from time to time, and Prof. Elihu Thomson is now coming forward with a new telephone system. Instead of a continuous dynamo or battery power an alternating current is used, but a current of such low periods of alternation—32 per second or so—that although the instruments respond the vibrations do not seriously interfere with speech, as the low hum they produce is almost inaudible in the instruments, and indeed can only be heard by specially listening to it, and then affords a test as to whether the lines are in order. All local batteries are dispensed with, the system having a closed circuit of great flexibility, and may be not grounded at all if desired. The annunciators at the exchange are worked by the simple act of lifting off the telephone, which momentarily opens the circuit. The system is described with diagrams in the *Western Electrician* for September 10, but it does not appear whether any application to an exchange has yet been made in practice.

High-Voltage Lamps.—The attention of incandescent lamp makers has lately been attracted to the production of high voltage incandescent lamps—that is, lamps of from 150 to 300 volts—and a short but interesting article on the subject is given by Mr. Henry E. Vineing in the New York *Electrical Engineer* for the 14th inst. He points out that by the use of such lamps the capacity of the lamps would be doubled. The quality of the glass is an all-important factor in the manufacture of incandescent lamps, and fully 90 per cent. of the maker's troubles are due to this cause, and the quality, he says, should be different for different voltages. Instead of lengthening the filament—the only fibrous material available for such lamps being bamboo—he advises a chemical treatment. He has succeeded in making lamps of a voltage ranging from 200 to 280, with a life of over 500 hours at 3·6 watts per candle by chemical treatment previous to carbonisation at 4s. per 1,000 filaments. High-voltage lamps do not blacken. There is a greater percentage of uniformity in candle-power. During exhaustion the fall of resistance is less in proportion than lamps of lower voltage. His conclusion is that makers of high-voltage lamps will find the solution of the problem in chemical treatment rather than in the use of mechanical devices.

Jerusalem.—The progress of modern civilisation leaves no corner of the earth revolutionised. With the first railway train entering into Jerusalem, bringing at last the steam engine within the sacred walls—a fact which was accomplished for the first time last week—we feel that civilisation, as we understand it, is advancing quickly. Cook's have already set up their tent in the Holy City. We suppose, now that Rome is lighted, Jerusalem can hardly tarry long before introducing the electric light, or even electric tramcars, and we shall hear of "transmission of power from the Brook Cedron," or other source of water power. It is perfectly true, however, that a steady migration of the Jews has been going on for some time

past into Palestine, and the renovation of the old cities under their business instincts is astonishing. The importance of Palestine as a centre between East and West is not less nowadays than it used to be, and with the introduction of railway trains, telegraphs, cars, and lighting along with the Jews, Palestine may regain its prestige, and perhaps not lose its associations any more than other countries have done. The modern colony may prove an important customer in the market, and the interest of the place for travellers of all countries should not make it less prosperous in the future than the Rhine or Switzerland.

Telephone Companies.—In all probability, the secret history of the fine splash made by the New Telephone Company and the neat collapse at the psychological moment of the promised competition will never be fully written. The combination is pretty complete, apparently. The offices of the "New" have passed over into the ancient enemy's camp, and the officers are working in the once hated corner of Oxford court, whence the National spreads its network of wires. The combination was effected, we believe, by a gentleman entirely unknown to electrical fame, stung by the apparent waste of energy (and money) likely to accrue—a mutual friend of both—and once a path was found the two opposites met as quickly as positive and negative. The final result, we may venture to predict, will be that the National part of this electrical centaur will keep and work their provincial business, which is already well organised, well erected, and well maintained in most parts of the country; but that the "New" part of the combination will take the large towns, reorganise as soon as possible the wiring on the twin-wire system in London as in Manchester, and at last, let us hope, we shall have a decent and not too dear service. The question of active competition will be settled, though the true solution in the Government acquisition of the monopoly is yet as far off as ever.
